THE LAWS OF PIGMENTATION AND THEIR BEARING ON MEDICAL SCIENCE.

By A. Bleloch, M.A. Glasg., Sc. D. Edin.

Cutaneous discolorations in so far as they are not the result of bile pigment misdirected to the dermal surface with the current of blood, or partake of the nature of blood extravasation in the cutaneous tissue, are closely allied with all natural pigmentation. The natural pigments are all carbonaceous. An exception has been supposed to exist in the green of feathers and the red of beetroot. Be this as it may, all other natural pigments are carbonaceous, and they are produced in each separate plant and animal according to its climate, type of life, and means of nutrition. That the exhibition of colour in plants and in animals is regulated by a fixed law, does not admit of dispute. Climate, type of life, and means of nutrition form, as it were, the sphere in which this law of pigmentation operates. In tropical countries where there is abundance of moisture, a very high temperature, and intense light, we have also a luxuriant vegetation and a very rich inflorescence. The plants fix their carbon in greater quantity, and hence their blossoms are more brilliant, and their foliage more ample. The plumage of birds is more brilliant in warm climates because the atmosphere is much rarer, and the natural temperature of the animal does not require any great consumption of carbon by the lungs. As we travel towards the pole, pigmentation in plants and in animals decreases. The inflorescence of our native plants is very tame when compared with the tropical beauties; and in still colder countries the difference is more marked. In the animal kingdom, except where the type of life and the means of nutrition prevent a diminution of pigmentation, the phenomena of colour are the same. In our own country the ptarmigan and the mountain hare become white during the winter, because they breathe more oxygen and have not such an abundant supply of food during the cold months. They use all their carbon for purposes of temperature. So also the common squirrel, which is brown in the more temperate countries of Europe, is snow white in the dreary forests of Siberia. The Polar bear is white, not because nature intended him to be white in particular, but because her carbon in his case is otherwise employed. So with the other Polar land animals. The temperature of the water, however, is much higher than that of the land, and hence the animals living in the Polar seas exhibit colour. Pigmentation observes this law in man himself. The skin of all the races of men possesses a pigment-secreting function. This function is active or the reverse according to their climate, their habits, and their means of nutrition. Two causes operate in particular to effect the pigmentation of the negro. He lives for the most part on vegetable food, and he inhabits a country whose climate is very moist and very warm. He has an abundant supply of carbon, and a deficiency of oxygen to carry it off by means of respiration. Hence the pigment-secreting function of his skin is called into special activity. He excretes carbon by his skin. When the brownish-red negro of the north of Africa migrates to the marshy districts further south, in course of time he becomes jet black, thus proving the doctrine advanced. It is also confirmed by the Esquimaux, a coloured race. In their habits the Esquimaux approach the Negro. During nine months of the year they are crowded together in small huts badly ventilated, and they live almost entirely on carbonaceous food.

From the foregoing brief review of natural pigmentation, we conclude that the production of colour is effected in the same manner in both animal and vegetable organisms. In physiology we expect to find the phenomena of colour the same in both kingdoms. Whatever pigmentation is natural in the animal is produced after the same fashion as in the vegetable. In physiology, nature has but one law of pigmentation. In animal pathology connected with discoloration we may expect to find a retrogression to the vegetative type. In the vegetable kingdom the production of chlorophyll is, as it were a chief function. It is paramount in vegetative physiology; In the higher animal kingdom it is reduced to a minimum because the economy of the living being no longer requires

and no longer admits of, this arrangement. The exception in the case of the coloured races of man is more apparent than real. The excessive pigmentation of the negro is produced by an augmentation in the activity of a natural function. This exaltation of function arose, as must be supposed, in the school of adversity; it originated in a pathological condition induced by a course of endemic disease during which the negro became acclimated. The consequence was not merely a discoloration of the skin, but a depreciation of the entire organism. The heredity includes more than a coating of carbon. There can be little doubt that the coloration of the negro is closely allied physiologically with the lower ethnic skeleton, that in fact the excessive excretion of carbon by the skin indicates a retrogression in the whole economy. As a strumous European, in so far as his skeleton is concerned, resembles a healthy negro, so the normal coloration of the negro would indicate a very cachectic European. In accommodating the negro to a lower physiological type, nature has made a great conquest. She proceeds on the same plan to combat all disease. The human body is a very elaborate organism. Specialisation of function is carried to a very high pitch; but the general structure is so wisely arranged that one organ can assist another in an emergency. When disease of one organ threatens the general well being, one or more come to the rescue, and, though not always successful, they seldom fail to render valuable assistance. The evil day is put off. For the time being, nature carries on her operations according to a lower type of life. She stoops to conquer. This is the indication in all cutaneous discolorations.

There are three points of view from which the pathological production of pigment may be regarded. It may be the result of the imperfect oxidation of carbon, so that it is not eliminated as carbonic acid, lactic acid, and such like. It may be the result of imperfect elimination of carbon proper, when that is a normal excretion, as in the hairs and epidermic scales. It may be the production of carbon from highly carbonaceous food. When the blood corpuscles become impaired as oxygen carriers through a deficiency in the hæmaglobin, the normal excretion of carbon waste will not be effected by the usual channels. We are thus enabled to understand the pigmentation which takes place in cases of Leucocytosis, in the anæmia of chlorosis, in Bright's disease, and in all cachectic states in which the hæmaglobin is defective in oxygenating power. In addition to defect in hæmaglobin as such, impaired action of the lungs from whatever cause leads to imperfect elimination of carbon as carbonic acid. There are also conditions of the liver and kidneys which result in the imperfect elimination of the colouring matter of the bile and urine. The excretion of carbon is, in these instances, thrown upon the skin and mucous membranes, and even glandular structures and morbid growths take on a carbon secreting action.

Pigmentation in connection with the function of generation is interesting and important. The menstrual fluid is highly carbonaceous. It is most likely of the nature of a carbon excretion. The elimination of carbonic acid by the lungs during the menstrual period has been shown to be less in quantity, and the condition of pregnancy is characterised by the production of pigment. The blood during the period of gestation approaches the condition in which we find it when cachectic cutaneous discoloration exists—there is an excess of white corpuscles. Besides, it has been shown that supra-renal melasma has relations with the sexual hair and cutaneous glands. The supra-renal capsules, the ovaria in the female, and the testes in the male are closely associated by means of their nervous supply. Pigmentation in animals, as in plants, is intimately connected with seed production. In order to the formation of the embryo plant and its proper nourishment, a large quantity of starch and sugar is necessary. In plants the storing up of this material is indicated by a superabundant production of chlorophyll. In the animal kingdom there is a provision of like nature for the embryo animal, and there is a corresponding deposition of pigment in the dermal surface. As in the vegetable kingdom chlorophyll is more largely produced during the season of vernation and inflorescence, because special provision is being made by nature for the production of seed; so in the higher animal kingdom she has not wholly left the vegetative type, but maintains a community of operation in both kingdoms, as far as the embryo plant and animal agree in their mode of development and nutrition. During the pregnancy of the human female we have a peculiar areola round the nipple, the colour of which increases in intensity as the period of gestation advances. Analogy would refer this to the fact that nature has to provide nutrition for the fœtal life. Starchy substance, or glycogen, is found to be present in the placenta, and that it is there for the service of the fœtus does not admit of doubt. The areola round the nipple is the complement of the physiological process by which this substance is formed, just as the luxuriant green of Spring and the splendid inflorescence of Summer indicate the provision which nature is making for the embryonic plants about to be evolved. During pregnancy we have a condition of the blood resembling Leucocythemia, but this must not be considered a pathological state. It is simply the way in which nature brings to perfection her arrangements for the growth of the new animal. In some plants the whole force of life is expended in the elaboration of the seed. To accomplish this the human female recedes one step towards the type of vegetable life. The blood becomes a less efficient oxygen carrier, while more than the usual amount of starchy material is manufactured; and as the condition of blood necessary to, or induced by, this formation does not admit of carbon in the normal quantity being excreted by the lungs in the shape of carbonic acid, nature deposits it as chlorophyll in the animal as in the plant. The natural pigmentation of the human body will be the index of the normal condition of the glycogenic function, just as the extraordinary pigmentation during pregnancy is the index of its additional activity for the service of the fœtus in utero; while all cachectic cutaneous discolorations will indicate a retrogression to the vegetative type beyond that which is required in the healthy condition of the economy. Examples of these discolorations are presented to us in the syphilitic cachexia, in the cancerous cachexia, and in the cachexia of Addison's disease.

The nervous system has to do with pigmentation. The symmetrical deposit of pigment and the occurrence of Leucopathia without any known local disease of the skin indicate this. Wherever a nervous system obtains, it modifies all physiological changes. The numerous organs which in the animal economy operate to produce the general effect of healthy nutrition and growth, are directed, in their several capacities, by appropriate nerves. Each organ moves on harmoniously with the others, while a state of health continues, because nothing can be done without the sanction of some nerve centre. Animal pigmentation is, therefore, under nervous control. As the result of investigation, it has been determined that the changes of colour observed in the skin of the frog and the chameleon, under varying conditions, are due to the influence of the nerves distributed to the pigment cells. In the course of these observations it has also been determined that the cerebro-spinal axis is chiefly concerned in regulating the functions of the pigment cells. Pigmentation, however, whether governed by a nervous system, as in the animal kingdom, or produced without such regulations, as in the vegetable kingdom, observes the same economical law, and is equally the index of glycogenic change.

When a man builds a house he procures artificial colours and paints his saloons and apartments. Nature does nothing of this sort. The production of colour in the physiology of living beings is not a result of design in the sense of being aimed at, but takes place when the economics of the organism so require. Even when the coloration is not produced by carbon in any form, as by the grooved structure in the wings of certain lepidoptera, it is not contemplated

for its own sake. The light falling on the scales of many fishes produces beautiful coloration, but this is not a design in the structure of the fishes. The grooved surface on the wings of the lepidoptera subserves the purposes of flight. The organ is so constructed that it may be at once light and efficient. The scales of the fish are formed according to the principles which govern the economy of the animal. They are made with groovings and polishings, and are set at angles such as shall most efficiently aid the animal in its progress through the water, and protect it from external injury. The coloration in both cases is present apart from any design as to colour in the construction of the animals. The beauty is the result of perfection in mechanism, the complement of adaptation to the conditions of life. The principle is the same in natural as in physical science. All carbonaceous pigmentation is economical whether it be in physiology or pathology.

From all these considerations it follows that in observing clinically cutaneous discolorations, we must note them in relation with the general physiological laws in accordance with which they arise. Race, sex, and age must all be taken into account. In order that our observations may lead us to a scientific treatment of disease, we must be able to connect the discolorations with the pathological conditions of which they are the complement. In order to this we must settle it in our minds that in producing pigmentation, nature has but one object in view—namely, to maintain the living organism. This is her aim whether it be in exhibiting the chlorophyll of the plant, or the coloration of the palate of the well-bred dog, or the discoloration of the palate of the cachectic human being. To cure diseases attended with cutaneous discolorations, is to assist nature to carry on her operations according to the normal type of life which she has set up for the particular organism.

ON THE PROSPECTS OF THE SEWAGE QUESTION.

By Henry Letheby, M.B., &c.,

Professor of Chemistry at the London Hospital Medical College, Medical Officer of Health to the City of London, &c.

(Continued from Page 509.)

In a former communication to you I spoke of the investigations of Dr. Angus Smith on the polluted water of the Clyde, which were to the same effect. Engineers also, who have been largely concerned in such inquiries, have always spoken of the remarkable self-purifying power of water. Mr. Hawksley, whose experience of this matter renders him a very high authority on the subject, said, in answer to a question from the Rivers Commission, as to the quantity of water, compared with the volume of sewage discharged into it, as necessary for the purpose of breaking up the sewage into inoffensive compounds, that generally 20 to 1 was sufficient; but if the water flows rapidly, and is very much disturbed, so as to be continually receiving fresh oxygen, a smaller quantity—even 12 to 1—will effect the process; and if it proceeds very tardily it may take a little more, but 20 to 1 is abundant. "I could," he adds, "give you very remarkable instances of it. Take Sheffield. Nothing can be fouler probably than the state of the water at Sheffield, whereas if you go down to Doncaster (about 20 miles below Sheffield), the water is supplied by the water-works, and is actually drunk in the town." Again, says Mr. Hawksley, "Take the river Irwell, (the very river which Dr. Frankland has been examining). After leaving Manchester it receives the Irk, the Matlock, and all the refuse of the manufacturing population for a great many miles; when it travels down only eight or nine miles to Warrington it is perfectly changed; it ceases, or nearly ceases, in that short distance, to be an offensive river." "At Leicester, likewise," to use his words, "the water was as black as ink—nothing would live in it, and the smell was abominable; but by the time it had got to Loughborough (which is about twelve miles below Leicester) it was entirely restored to its pristine condition. You could stand on the bridge there and see the fish swimming amongst the beautiful reedy and other plants growing in the water, just as in the purest stream. You could see every pebble at the bottom. That is an instance of oxidation." You may remember the instance which I gave you last year of the river Trent, which receives the sewage and manufacturing refuse of some of the largest, busiest, and dirtiest towns in the kingdom, with an aggregate population of more than a million and a half of persons, and yet when it arrives at Nottingham it is not only clear, pellucid, and inoffensive, with abundance of fish and aquatic plants, but is actually used for the domestic supply of the town. But why need I multiply such instances, or dwell upon such self-evident empirical facts, when they are within the common knowledge and experience of everybody; for even Dr. Frankland is ready to admit, in the case of the London water supply, that "by gradual oxidation, partly in the pores of the soil, partly in the Thames and its tributaries, and partly in the reservoirs, filters, and conduits of the company, this sewage contamination had been converted into comparatively innocuous organic compounds before its delivery to consumers."

"I believe," said Dr. Frankland, in his evidence before the Royal Commission on Water Supply, "that the noxious part in sewage is that which is held in mechanical suspension, not that in solution;" and no doubt the sedimentary matters of sewage are capable of producing an offensive condition of the rivers, for when they are discharged into a sluggish stream they quickly subside, and form accumulations of persistently putrefying mud. This is the chief cause of complaint wherever sewage enters a river.

At the time of the inquiry into the state of the Thames in 1858, it was admitted on all hands that the filthy mud-banks of the river were the great source of annoyance; and Dr. Hofmann and Mr. Witt, in their report of the matter to the Government referees, declared emphatically that the formation of this mud deposit in the bed of the river appeared to them to be by far the most serious evil which results from the discharge of London sewage into the river, and they strongly urged this point upon public attention. Dr. Odling, in his report to me on this subject, for the information of the referees appointed by the Metropolitan Board of Works, said that "any means which would prevent the deposition of organic mud in the bed, but more particularly on the exposed banks, of the river, would effect an amply sufficient purification of it." The same was my own opinion, for in reporting to the referees I stated that the mischief produced by the discharge of sewage into the river "was not occasioned, as I once supposed, by the soluble matters of the sewage, but by the mud or insoluble constituents which settle and putrefy upon the banks of the river." These constituents being in a solid form, and not easily accessible to atmospheric oxygen, continue to putrefy for a considerable time. In my laboratory operations I have found that they will keep up a persistent decomposition, with a constant evolution of offensive gases, for many months, the air being excluded from them. I am therefore of opinion that the chief point to be aimed at in the purification of sewage is the rapid and effectual separation of its suspended matters, leaving the soluble matter to mix freely with proper proportions of running water, in which it will be quickly appropriated by infusorial life, or be destroyed by atmospheric oxidation; and this leads me to consider the means whereby this may be effected.

One method of accomplishing it is to keep the solid matters out of the sewage, as is practised with more or less success in Manchester, Salford, and chief towns of Lancashire. In Salford, according to the report of the medical officer of health, Dr. Syson, the most satisfactory results have been obtained with a modification of N. Goux's plan, whereby the soil is received at once into tubs lined with some refuse absorbent; and the advantages of the plan, according to Dr. Syson, are that the manure becomes of

great commercial value; that the excrement of the whole town can be readily removed at least once a week; and that in case of fever or contagious diseases the whole of the excrements can be readily and economically disinfected; besides which the plan is simple and economical. Earth-closets are not so manageable, as they require about 3½ times their weight of earth to the excreta, and the difficulties of carrying the material to and from the closets are not manageable on a large scale, although I have seen them in satisfactory operation in factories, as they may be in military camps, where the organization of labour is easy. Instead of earth, Mr. Stanford recommends charred seaweed, which is not only an excellent deodorizer, but does the work of three times its weight of earth. In Edinburgh in olden times there were no closets in the poorer houses, but there were numerous public privies, which still exist. These are provided with from 8 to 40 compartments, beneath which there is placed by the scavengers, every morning, a tin can, like the modern milk can on the railways, and the can of the previous day, with its contents, is taken away. The soil is mixed with ashes and road sweepings, and sells for about £7,000 a-year, which is half the entire charge of the scavenging of the older part of Edinburgh. Nearly everywhere on the Continent some such method is adopted for the collection of the refuse and excreta, and they are profitably utilized. How far an improvement of this condition of things, instead of the present water-closet system, may have met the requirements of hygiène and the demands of agriculture, is an important question. The Pollution Commissioners, however, condemn this plan *in toto*; and so far are their views disturbed by the medium of their predjudices, that they cannot perceive any difference in the quality of the sewage of a place retaining its solid matters, and of another which lets them flow into the public sewers. Liverpool, for example, which collects and disposes annually of about 139,000 tons of privy soil; Manchester, 74,000 tons; Salford, 46,000 tons; Oldham, 50,000 tons; Preston, 30,000 tons; and Bolton, 22,500 tons, furnish in each case as much sewage, and of the same composition, as the towns which discharge everything into the sewers. The inconsistency of the thing is so striking that it creates most serious doubts of the accuracy of the analyses and of the reliability of the determinations of organic carbon and organic nitrogen.

And now let us turn to the pet scheme of the Pollution Commissioners—the disposal of sewage in all places and under all places and under all circumstances by irrigation. Fortunately for us, the thing has been tried, and is now being done in many places, so that we can test it by its practical results, and examine it by the light of something more than that of abstract speculative chemistry.

To begin with its absolutely required conditions. You must have a soil that is sufficiently porous to allow the sewage to filter through it, and this soil must be well drained to carry off the subsoil water. The situation of the farm must be convenient as regards the flow of sewage to it by gravitation, and the discharge of water from it by drainage. It must not be within reach of danger from atmospheric miasms, or the pollution of wells by the subsoil drainage. It must have a ready market for the disposal of its only merchantable produce, green Italian rye-grass; and lastly, there must be an area of not less than two acres for every hundred people, one of these acres being actually in use while the other is resting to recover itself.

These conditions cannot always be secured, but, even if they could, let us see if the objections to the process, on sanitary grounds, are not conclusively against it.

1. In the first place, the land irrigated with sewage is always a fœtid, swampy morass of the most offensive description. Nowhere, of all the places which I have visited, is there an exception to this condition of things. At the Craigintinny meadows, near Edinburgh, which I have often seen, the stink from them is hardly endurable—to use the words of Dr. Ligertwood, who was stationed at the neighbouring barracks, "the stench is sometimes quite sickening." At Norwood and at Beddington it is a subject of serious complaint by those who reside in the neighbourhood of the farms. I have myself experienced it on several occasions, and have been surprised at the statements of Dr. Carpenter, of Croydon, whose pet thing it is, that nobody complains of it. Mr. Creasy, the surgeon at the Female Orphan Asylum, at Beddington, tells a different story, for he says it so damages the value of the neighbouring property that the villas near the farm do not let so well as others, nor at so high a rent.

At Aldershot, which is frequently referred to as a well and successfully managed sewage farm, I ascertained, on a recent visit with Mr. Hawksley, Mr. Eggar, and Professor Ansted, from the occupants of the few cottages which skirt the farm, that the stench is frequently unbearable and most sickening. At Banbury there is but one house upon the estate; it is a public-house called the Bowling Green, and the landlady described to us, in very graphic terms, the nuisance she was obliged to submit to.

2. But these miasms are not alone offensive, they are also dangerous to the public health; in fact, the early proceedings of those who have brought about this condition of things were devoted almost entirely to the proof of their morbific action, and it was this apparently clear proof which was made the lever of their parliamentary movements, and was the main cause of our present difficulties. Now, however, they will tell you that the emanations from acres of land sodden with putrefying sewage are neither offensive to the senses nor injurious to the health. I put it to you, gentlemen, as a simple matter of common medical experience, whether you are of such an opinion; for, if so, where is the necessity for all our elaborate and expensive machinery for getting rid of these matters from our houses, and for preventing the escape of such offensive emanations? Why feel, in fact, the least concern for an untrapped drain or an overflowing cesspool? One of the highest medical authorities on the subject of fevers, Dr. Murchison, has traced a particular fever to this particular source, and has devoted a large portion of his classical work to the proof of sewer gases being the primary cause of what he has termed *pythogenic* or enteric fever. It is true that he has some doubts, like Dr. Christison, of the effects of the diluted gases; but time will prove whether these doubts are well founded. Already enough has been seen to show that they are not so harmless as many suppose. Mr. Creasy, to whom before I have alluded as practising at Beddington, said very recently, before a committee of the House of Commons: "I know the sewage farm belonging to the Croydon Board of Works, at Beddington, and have had experience in my professional capacity of what condition of health is around those flats, for I have known the district ever since it was a sewage farm. The first case of typhoid fever occurred in the place in 1867, and from that time to this there has been typhoid fever in every cottage on the estate; and I find around it that almost every disease assumes a particular type, accompanied with what we call a sewage tongue."

In the Spring of last year I was inquiring into the condition of a stream called the Hebble Brook, which receives the sewage of Halifax, and I was informed that at a place near the outfall of the brook into the Calder, some of the sewage was distributed upon the land, and that it caused such a serious outbreak of typhoid fever in the neighbouring model village, belonging to Mr. Acroyd, that it was found absolutely necessary to discontinue it.

Again, in the Autumn of 1863, I had an opportunity of witnessing, on a very large scale, the morbific effects of sewer gases in the town of Shaftesbury, and the adjacent village of Enmore Green. The town had been recently drained by a gentleman of no great practical acquaintance with the subject, and he carried the sewage into the ponds and ditches around the town. It was an experiment of a very instructive kind, for soon the people were attacked with enteric fever, and in less than a year one-eighth of the whole population was down with the disease; for out of

about 3,500 persons, 448 were attacked. I am afraid, therefore, that these miasms, even when diluted with air, are capable of producing serious mischief, and that such facts are more more conclusive than the statistics of Dr. Carpenter, which seem to show that the people of Beddington and Norwood have actually been better in health since the sewage was brought to them than before.

3. I would remind you that the efficacy of sewage irrigation is entirely dependent on the percolation of sewage matter, and the distribution of it through the subsoil water. It cannot but be, therefore, that this water is polluted to such an extent as to endanger the neighbouring wells. Many instances of this have already come under my notice; and it would seem, from the remarks of Dr. Carpenter, that Dr. Frankland had himself stated that the chalk well at Croydon, from which the public supply is obtained, is actually polluted with the soakage of foul matters from the irrigated grounds at Beddington. The morbific effects of such water are but too frequently observed, as the annual reports of the medical officer of the Privy Council abundantly testify; and then, again, if the doctrines of Professor von Pettenkofer, of Munich, be correct, as they certainly seem to be, that fluctuation in the level of ground water charged with sewage is the most active agent of fever and cholera, the consequences of irrigation may be most serious.

4. And now there is another very important objection to the system—the danger of propagating parasitic diseases. Sewage contains myriads of ova of intestinal entozoa—every segment of a tape-worm discharged from the human body is crowded with them; and, if distributed with sewage upon the land, will become attached to the grass and other green fodder which is produced thereon. This is eaten by cattle, whose bodies quickly become infected with the parasite in its larval condition, and thus the measly meat becomes the agent of disease in our own bodies. At present, the distribution of these ova, and their access to the bodies of herbivorous animals, is entirely a matter of accident; but make it a matter of certainty, as most assuredly you will by distributing sewage upon the fodder-producing land, and the consequences must be serious. Dr. Cobbold, who is our highest authority on this subject, has published an essay to warn the public against the danger of this method of disposing of town sewage; and he has hinted at the probable introduction into this country of a terrible helminthic malady (*Bilharzia*), which is now common in Egypt, in Africa, and the Mauritius, and which would assuredly be propagated throughout the land by this dangerous scheme of irrigation. "Have the kindness," he says, "to observe that every colonist returning from the Cape is liable to bring this parasitic treasure with him as a 'guest' indeed, dwelling in his blood, and feeding on his life stream. In the advanced stages of the malady, the afflicted individual must frequently evacuate the eggs and their contained embryonic larvæ, which are thus conveyed into the ordinary receptacles of such voidings. There let them remain, or convey them into a cesspool, and no harm follows. If deemed preferable, you may transport them, along with myriads of other human parasite eggs and larvæ, into a common sewer, and thence into the sea; still, entozoologically speaking, no harm follows. Here, however, let me invite you to pause; for if, without due consideration, you adopt any one of the gigantic schemes now in vogue, you will scatter these eggs far and wide; you will spread them over thousands of acres of ground; you will place larvæ in those conditions which are known to be eminently favourable for the development of their next stage of growth; you will bring the latter in contact with land and water snails, into whose bodies they will speedily penetrate; and, in short, you will place them in situations where their yet higher graduations of non-sexual growth and propagation will be arrived at. After all these changes, there is every reason to believe that they will experience no greater difficulty in gaining access to our bodies here in England than obtains in the case of those same parasites attacking our fellow creatures, whose residence is found in Egypt, in Natal, in the Mauritius, or at the Cape. In the natural history point of view, it would not be an altogether singular result if, 20 years hence, this parasitic malady should be as prevalent in this country as it is now known to be in particular sections of the African continent. Foreseeing the possibility, not to say probability, of this contingency, am I not right," he says, "after years of long study, to raise my voice in the hope of preventing such a disaster?"

Nor is it unlikely that the Trichina may be distributed in the same manner, for it swarms in the intestines of those who have just become infected with it, and may be discharged into sewage, and scattered upon the land, and eaten by creatures whose flesh will give it back to us again. No one, indeed, but the helminthologist can say what particular parasite may not be distributed and propagated by this dangerous agricultural process. "May we not indeed," as Dr. Cobbold observes, "but too reasonably conjecture that the wholesale distribution of tape-worm eggs by the utilization of sewage on a stupendous scale, will tend to spread abroad a class of diseases, some of which are severely formidable? So convinced am I," he says, "of the truth embodied in an affirmative reply to this latter query—so certain am I that parasites are propagated in this particular way—so surely do I foresee unpleasant results, if no steps be taken to counteract the evil, that I feel myself bound to speak out boldly, and to produce no uncertain sound in the matter which most closely concerns humanity." The whole question, in fact, is of vast hygienic importance.

But, fifthly, let us see if the process, in a sanitary point of view, is so successful as to render the sewage innocuous before its admission into a running stream. Go to a sewage farm after you have given due notice of your intended visit, and you will be taken to places where the subsoil water is running from the land apparently pure and drinkable; and no doubt with proper management, under proper conditions of thorough and effective filtration, such a result may be achieved; but the real question is how far this is really and practically accomplished, for it involves such a nice adjustment of all the appliances, such a continuous distribution of the sewage over successive areas of land, and such constant supervision, that it is rarely effected. To judge of the results, therefore, you must visit these places, as I have done, without previous notice, and you must examine the whole district, for it is not uncommon to find byways for the disposal of the sewage which the land will not take. Not long ago, as I have said, I visited Aldershot, with Mr. Hawksley, Mr. Eggar, and Professor Ansted. This you know is a pet place with the advocates of the system, but at the time of our visit we found that nearly all the sewage was passing along the carriers to the outfalls, and going bodily into the river. I took samples of the sewage as it entered the farm from the two camps, and as it flowed from the farm to the river. The original sewage contained 54 grs. of soluble matter per gallon, and 44 grs. of insoluble, each of which contained about 30 grs. of organic matter. As it left the filter tank it contained the same amount of soluble matter, and 35 grs. of suspended, of which about 26 grs. were organic. As it ran along the carriers to the lower part of the farm, it retained its black offensive character, and this was very marked upon that portion of the land where a little of it was disturbed. At one of the outfalls into the Blackwater river it contained 52 grs. of soluble matter per gallon, of which 28 grs. were organic, and 3·84 grs. of suspended matter. At three other outfalls from the farm the soluble matters amounted respectively to 52 grs., 58 grs., and 54 grs. per gallon, of which 24 grs., 20 grs., and 22 grs. were organic; the suspended matters being 26 grs., 6 grs., and 5 grs. per gallon respectively, of which 12 grs., 2 grs., and 3 grs. were organic. At the several points of discharge into the river the sewage was black and fœtid, and there were large accumulations of sewage mud in a high state of decomposition. I took a sample of the river water before it received the outfall sewage and after; the

former contained 19 grs. of soluble matter per gallon, and the latter 24 grs., of which the organic amounted to 3½ grs. and 5 grs., the ammonia in the two cases being 0·264 of a grain, and 1·545 gr., showing an enormous pollution of the river by the so-called defœcated sewage. Everywhere upon the land where the sewage had been distributed there were masses of fœcal matter, waiting for the first heavy shower of rain to wash them away into the nearest outfall, and the neighbouring ditches were in a most offensive condition, and we were told by the occupants of the houses adjoining the farm that in times of flood the whole roadway was covered with sewage matters. Considering the praise which has been bestowed on the alleged success of this farm, I was not prepared to witness such a frightful condition of things.

At the Craigintinny meadows, near Edinburgh, it is notorious that the outfall water from the farm is shockingly offensive, but as it runs into the sea it is not complained of as a nuisance. A like condition of things, but not to such an extent, I have seen at Norwood, at Rugby, at Warwick, and at Banbury—in fact, at the last-named place the ditches around the farm were full of sewage, and the water was running from the outfall in a very offensive state, showing that the process, although susceptible of good results, is rarely so in practice, unless it receives an amount of attention that makes it a serious business. Besides which there are times when no attention will prevent the discharge of foul sewage from the land, as when the soil is heavy, and a flood of rain sweeps over it, and when vegetation is dormant. In winter time it will freeze upon the land and kill the grass, and, as it thaws, run off to the nearest stream. At Warwick we saw acres of ground thus despoiled, where the defœcation of sewage was entirely a matter of surface filtration. All authorities, indeed, agree that the success of this process is dependent upon a combination of circumstances which are not always attainable, and upon the strictest care and supervision. Even then, according to Dr. Frankland, although it may purify sewage to a great extent, it does not sufficiently purify it to render it admissible into potable water without danger; "the risk arising not only from the considerable amount of animal organic matters which the effluent water still retains in solution, but also from the absence of any guarantee for the removal of the germs or other noxious suspended matters which are frequently present in sewage."

(To be continued.)

DOCTORS AND TEETOTALLERS.

By a Physician.

The subject of alcohol is one of the most stirring of the present time in the domain of hygiene. Is there anything like orthodoxy to appeal to in this, as there is in some other medical questions? Are the members of the medical profession by any means so unanimous in their condemnation or in their approval of the habits of modern society in partaking of alcoholic drinks as they are on the question of vaccination as a preventive of small-pox? The answer, we maintain, must be in the negative. There is nothing like unanimity on this point amongst us. Such being the case, it behoves each of us to argue the question by the lights that are in us, without in any way appealing to authority. Well, as far as we ourselves can see, there can be no doubt that the teetotal party can make out an admirable case when they assert that a very large proportion of the disease and crime among us is traceable directly to the use of spirituous liquors in some form or other. Specialists, who devote their attention to diseases of the kidney, the eye, or the brain, will at once probably corroborate our assertion, that hosts of cases of disease in these organs are traceable to alcohol. The pallid and dull skin of the habitual drinker is well known to the hospital physician; the bronchitis and emphysema of old drinkers is one of his most common experiences. Gout, and dropsy, and disease of the heart are the usual terminations of the lives of swillers in our large cities. What is there to be said on the other side? The doctors who advise us to use beer and wine daily at our chief meals say that we are living in "an artificial state of society," and hence require stimulation to get through the wear and tear of existence without breaking down. This looks well in theory, but does not hold true in nature; at any rate, in all cases. Those persons—and they are not a few—who have witnessed the practice of hydropathic institutions, know well that many persons who are accustomed to habitually partaking of a certain number of glasses of wine or pints of beer daily find the simple fare and unexciting beverage there obligatory more conducive, in most cases, to health than their ordinary more exciting *régime*. And persons who train for prize-fights or for boat-racing are obliged, if they would quickly get rid of the softness of their tissues and attain to good wind, almost entirely to abandon all their beer and wine for a time. If such persons often become ill and die young, it is that they are often very idle and intemperate when not in training. Boerhaave said truly that water-drinkers live longer, have a better appetite, and preserve their sight longer than those who drink beer,—he might have added, or smoked tobacco, as he was, we think, a Dutchman. Our conviction is that alcohol is a medicine, just like opium, and should only be used for some temporary purpose, and steadfastly avoided by all persons as a daily part of diet. It is true that many persons can use opium daily, and seem to live pretty healthily notwithstanding; but the vast majority who do it are deeply injured and depraved by opium-eating or smoking: and, in the same way, the ingestion of alcoholic beverages cannot be defended, in our humble opinion, by any physician who has the facts in his recollection which we have alluded to above. There could not be many changes in civilized society to promise a greater improvement in human affairs than the abandonment of drinking of alcoholic liquors; and for more reasons than one. Our concern, of course, is not with the moral aspects of the question, except in so far as the use of alcohol takes away from the amount of money which its habitual consumer, if poor, is able to expend on nutritious food; the economical argument is not fit for our pages; but we have no hesitation in saying that the habits of gin and beer drinking in London and elsewhere produce a callousness to questions of human suffering and disease which would be certainly lessened if drinking were nearly abandoned. Brains sodden with gin and beer are less able to take interest in the great questions of the hour, the removal of pauperism and ignorance, than those left clear by the use of simple beverages such as the aromatic infusion. We are not in the least anxious, by these remarks of ours, to seem to dogmatise on what is evidently a difficult question. Doubtless, numerous persons, especially among the well-fed classes, are but slightly injured by the moderate amount of wine and beer they consume, whilst they are rendered gayer, and have more pleasures of a physical kind, from the moderate consumption of alcoholics. But, taking all things together, we are strongly of opinion that it would be much better for one and all of us to resort to aromatic infusions, such as tea and coffee, instead of using alcoholic beverages. Human life would be simpler, less costly, and more impressionable; besides which, hosts of cases of dropsy, of palsy, of atrophy, and degeneration would cease to sadden the physician's eye. Temperance in all things is good; abstinence from alcohol is one of the virtues which should be inculcated upon the young.

It is announced that a competitive examination for the admission of assistant-surgeons into the Royal Navy, to fill at least twenty-five vacancies, will take place at the London University on the 8th August, 1870, and following days, at ten o'clock.

Hospital Reports.

ROYAL FREE HOSPITAL.

At a recent visit to this hospital we found that an enormous improvement had taken place in the aspect of the wards. The magical effects have been brought about by the assistance of a nursing sisterhood, named the British Nurses Association, which is under the superintendence of Miss Coles. In company with the surgeon, Mr. John D. Hill, we were shown by that lady the admirable arrangements for the accommodation of the nurses, consisting of a dormitory and a parlour, as clean and wholesome as any one could desire. We predict that this will raise the subscription of that admirable hospital to a degree before unknown. With surgical skill, such as that of a De Meric, a Grant, or a Hill, we see no reason why this hospital should not take its place among the best schools of surgery in the metropolis. Its beds are always full of severe and most interesting cases.

ARMY HOSPITALS.

We begin, according to promise, our usual extracts from the new Army Reports.

Case of Resection for Disunited Fracture treated with Carbolic Acid.

By Assistant Surgeon W. Collis, R.H.A.

R. T., aged 22, belonging to F Battery C Brigade Royal Horse Artillery, sustained a compound comminuted fracture of the lower portion of middle third of the right tibia, by means of a kick from a horse which he was grooming.

He was taken to hospital, when the injury presented the following appearances :—

A contused wound extended an inch longitudinally along the bone, and about one inch and a half across it; the upper portion of the bone was riding to the extent of two inches over the lower, being also impacted into it to a considerable extent, whilst its spiculated extremity was forcibly pressed outwards, extending the sound skin. On passing the finger into the wound, three fragments of bone about one inch in size could be felt. The fibula was also obliquely fractured, but not comminuted; little or no bleeding took place, and the patient suffered but slightly from the shock. The fragments, being quite detached, were removed, a slight enlargement of the wound being found requisite. The patient was placed under chloroform, and extension and counter-extension used, when, after considerable difficulty, the fragments were placed in good position; the wound was then dressed with carbolic acid (one part of the acid to sixty of sweet oil) and closed up, several layers of lint saturated in the lotion, oiled silk and sheet lead being used for that purpose. The ordinary tibial splints having been applied and a bandage used, the thigh was flexed on the abdomen, and the leg on the thigh. A mild laxative with an anodyne was then given.

When seen next morning the patient was found to have passed a good night, no constitutional disturbances having taken place.

The case went on favourably, not a bad symptom appearing. On the tenth day the dressings were removed for the first time, when the wound was found entirely healed up, no suppuration whatever having taken place. The injury was then converted into a simple comminuted fracture.

Having left Benares for six months' leave to the hills at this stage, I am personally not aware of the history of the case during those months; however, a few days after my return, he was again brought under my notice.

I now found that the man whom I had left in an excellent condition was in a very debilitated state of health, in consequence of mental anxiety and extreme pain at the seat of fracture. Upon examination the fracture presented the following appearances:—The upper fragment of tibia overlapped the lower to the extent of about one and a quarter inch, and pressed strongly on the integuments. Complete union had not taken place between the fragments, motion being readily obtained by fixing the upper part of the leg and moving the lower. With regard to the exact state of the fibula some doubts existed, but it seemed almost certain that union had taken place. No deposit surrounding the seat of fracture could be determined.

The man being again admitted into hospital was given good nourishing food, rum being given as a stimulant. Under this treatment his general health very much improved; but all action had evidently ceased at the seat of injury, and the limb remained, not only perfectly useless, but a source of intense pain and an incumbrance to the patient.

The question of either amputation, resection, or some other procedure, had now to be thought of. I did not find much difficulty in deciding against amputation for the following reasons :—

1st. From the man's position in life, he would be left destitute and unable to get his living.

2nd. Knowing the constitution of the patient, it seemed likely that other and milder means would obviate the adoption of this ulterior one, and at the same time secure to the man a good and useful limb,—besides, as is common with natives, he objected most strongly to have amputation performed.

With reference to the other measures usually adopted in the treatment of disunited fractures, viz., setons, rubbing the ends of the bone together, ivory pegs, &c., the very unfavourable position of the fragments rendered them inapplicable to the present case. Resection of the ends of the bones, being thus the only course left open for adoption, was resolved on.

The patient having been placed under the influence of chloroform, I made a longitudinal incision over the seat of fracture along the spine of the tibia, to the extent of about four inches. I also made a cut at right angles to this directly over the protuberance caused by the riding of the fragments: this cut was about two inches and a half in length. The flaps having been dissected back the bone was exposed, and presented the following appearance :—

No surrounding callus existed, although there was some filling up of the interstices caused by the qualities of the fragments. Between the ends of these a considerable amount of callus had been thrown out; this was hard and very firm, but allowed an amount of semi-rotatory motion between the ends of the bones; of these the upper overlapped the lower to the extent of an inch and three-quarters. The extremities of the fragments had become smooth and rounded, and all reparatory action had evidently ceased. The oblique fracture of the fibula was found to be completely united, though an amount of longitudinal displacement existed; the shortening from this cause was, however, not considerable. No callus existed about the seat of this fracture.

The necessary operation was simple. I removed the overriding ends of the tibial fragments, with the included callus, to the extent of about three-quarters of an inch. The space thus formed between the ends of the fragments corresponded to the amount of shortening which had taken place in the fibula. The patient lost but very little blood, neither the anterior nor posterior tibial vessels having been met with.

Ligatures had to be applied to some small vessels—simple torsion was found sufficient for some superficial ones. The wound was allowed to remain for an hour exposed to the air as some oozing had taken place. At the end of this time, the bones having been placed in good position and a few sutures introduced to keep the edges of the wound together, it was thoroughly saturated with carbolic acid lotion of the strength formerly used. Pledgets of lint, saturated with the lotion, were placed on the wound, these again with gutta-percha tissue, the whole being made air-tight by means of oil-silk cloth. The ordinary leg splints having been applied and a flannel

bandage having been wrapped round the limb, the whole was kept in position by a bandage applied from the foot to the knee-joint. The thigh was now flexed on the abdomen and the leg on the thigh. Thirty drops of tr. opii was now given him; this quieted him considerably, but did not induce sleep. About 10 P.M. (14 hours after the operation) a similar dose was given, which had the desired effect, and the patient enjoyed a good night's rest.

14th Dec.—Patient very comfortable; complains of but little pain; pulse 104; temperature in axilla 100°; tongue slightly whitish, skin moist: ordered beef tea and dholl (a kind of Indian pulse); a dose of oil was also given.

From this date, up to the 21st of December, nine days after the operation, the condition of the patient continued most satisfactory, the pulse having fallen from 104 to 92, and the temperature of the body from 100° to 99°.

The appetite continued good, and the bowels were opened daily. On this date he complained of some uneasiness about the wound. The dressings having been removed, the longitudinal incision was found completely healed, with the exception of where the sutures interfered. The transverse cut was also nearly healed up, while the space between the ends of the bones was filled up with plastic material.

The ligatures being loose were removed: a very slight trace of pus was found present, resulting evidently from irritation caused by the sutures. The wound was dressed in a similar manner as after the operation.

30th Dec.—On the dressings being removed for the second time, the wound was found to be completely healed up; callus was forming between the ends of the bones most favourably. The general health of the patient is excellent. Wound dressed as before.

29th Jan., 1869.—Patient going on most favourably; callus continues to be thrown out; removed the splints and put on a starch bandage. Patient allowed to go about with the help of crutches.

Literature.

LECTURES ON SOME SUBJECTS CONNECTED WITH PRACTICAL PATHOLOGY AND SURGERY.*

Mr. Henry Lee is known to the Profession for more than one of his writings. As a writer on syphilis he stands among the best men in this country; and, indeed, so pre-eminent is he in this department of pathology, that we are hardly able to realise the fact that he is in addition to this an able general surgeon and scientific pathologist to boot. There are nineteen lectures contained in the volume before us. The first upon purulent infection; the three following on phlebitis; the fifth on varicose veins, and the sixth and seventh on varicocele and varicose veins; the eighth and ninth lectures treat of the repair of arteries, and on mortification, and other affections following disease of the arteries; lecture ten is on the diseases of the rectum; and lecture eleven on piles. The diseases of the rectum occupy most of the remaining part of the work; but in chapter eighteen he treats of long continued pains in bone, and in lecture nineteen on the excision of joints.

Several diseases, says Mr. Lee, have been grouped together under the name pyæmia. Some of them are different in origin, and probably not altogether allied in their pathology. But they all have a common tendency, sooner or later, to produce abscesses in different parts of the body. Up to the time of Virchow, the generality of surgeons admitted that the symptoms of purulent infection were due to the introduction of pus into the blood. When symptoms of pyæmia have actually occurred, but little is to be hoped from therapeutics. Three distinct affections have been described under the general name of phlebitis—viz., a primary inflammation of one of the larger veins of the body; the secondary affections, which occur in veins situated at a distance from the original lesion; and the general infection of the system resulting from the admixture of diseased secretions with the blood. Phlebitis has an undoubted existence. When some external injury has been applied to a varicose vein, and pain, heat, tenderness, and swelling follow, the symptoms leave little doubt of the presence of inflammation, and a coagulation of the blood at that part is the effect; but then the inflammation appears to have been propagated from without inwards. The coagulation caused by the phlebitis seems to be occasioned by some morbid impression made upon the blood through the lining membrane. Although it is undoubted that the internal coat is not liable to be inflamed in the same way as serous membranes are, there is no reason why it should not be affected with a perverse nutrition allied to a state of inflammation. In phlegmasia alba dolens, for example, the obstruction to the circulation generally results from the influence of the blood, of materials absorbed through the uterine veins. At one extremity the venous clot is multiple, adherent, and composed of root-like processes, extending into the tributary branches; the opposite extremity lying free in a large vein, and terminating by a large rounded end. The marks of phlebitis are rarely present. If the clot be of a simple kind, it will generally liquefy, and become so thoroughly disintegrated as to disappear, without leaving any trace of its existence, and without having induced any constitutional symptoms; but it sometimes happens that portions of the coagulum are detached and arrested in the heart or large pulmonary trunks, producing fatal forms of cardiac or pulmonary emboli. If several small portions are detached, or the *débris* of the clot carried away by the current of the blood, the particles become arrested in the smaller pulmonary vessels, and give rise to obstructions, local œdema, or a form of pneumonia of a less dangerous and active form than where the pulmonary emboli are formed of decomposing or putrefactive matter.

When a patient in other respects influenced by predisposing causes has been exposed to the influence of some mineral poison, or when a woman who has been recently delivered has been exposed to the erysipelatous or scarlatina poison, there is probably systemic poisoning from the first, out of which these secondary affections may or may not arise. We do not yet know on what the fluidity of the blood depends, and we cannot say why, at one time, the impression made on it by an animal poison should cause its coagulation, and at other times fail to do so. But Mr. Lee thinks that we are warranted in concluding that the liability to, or the actual occurrence of, coagula in these disorders, results from one of these conditions:—viz.: 1. Some injury or morbid alteration of the coats of a vessel. 2. The introduction of some diseased product or foreign material into the circulation. And, lastly, from the impression made upon the blood by the action of an animal poison. When secondary affections result from the two first of these, they will show themselves in the capillaries of the organ nearest in the course of the circulation to the place of the primary affection, or to that where the materials gained their entrance. When secondary affections are the result of the last, however, they may appear anywhere. The whole of this work is well worth reading, both because it is full of matter and because it is so readable. We can confidently recommend any of our surgical brethren to place it on the shelves of their libraries.

* Lectures on Some Subjects Connected with Practical Pathology and Surgery. By Henry Lee, F.R.C.S. Churchill, London. Pp. 309.

As an election for Dublin may be shortly expected, Sir Dominic Corrigan has announced himself as a candidate, and, as the list of voters has been greatly modified since the last contest, he may probably go in without opposition. Our Profession will then have an able exponent of its views; and, if he had already possessed a seat, it is questionable whether so inefficient and hurtful a measure as the Government Medical Bill would have been introduced.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 6, 1870.

THE MEDICAL REFORM CRISIS.

The Government Bill has passed the House of Lords. Clause 18 has been restored, and some amendments withdrawn. That is the news of the week, and although Clause 18 gives the Bill some slight value, it is by no means such a measure as will give satisfaction, or last a long time. It must, therefore, be attacked in the Commons. What does it effect? It sets up three portals into the Profession, one for each of the three kingdoms, as if medicine were a different science in London, Dublin, and Edinburgh. The Profession cries out for a single portal. Let the three United Kingdoms be seen to be really united so far as medical licensing is concerned. A single imperial diploma, giving the right to practise every branch of the art of healing wherever the Queen's authority prevails, would be the best protection for the public, give the most satisfaction to the Profession, and interfere least with the examining bodies.

The Universities and Corporations might then make what rules and regulations they pleased. They would only be forbidden to grant their honours to unlicensed persons. Justice would thus be done. Those Universities and corporations whose diplomas were of real value would have plenty of applicants for them; and if a few were really useless, they would quietly die out, or amalgamate. This is the great reform that all earnest men have for years demanded, and the Government Bill gives us only a feeble attempt at compromise—a wretched three-portal system, possessing the elements of competition downwards, and sowing the seeds of jealousy between the three "United" Kingdoms. What is to keep three examining boards to the same level? If that were possible, what is to convince students or others that the level is the same? What is to prevent the licentiate of the Irish Board from sneering at his neighbour as the possessor of a "Scotch diploma," or the two trying to persuade the public that the English licentiate is more easily passed than the others? If we are to have a change, let us have a measure that shall effectually settle all such differences. Give us a single State licence. Let that be the sole entrance into the Profession, and we will decide for ourselves what other diplomas we will take as honours.

There is a worse feature still in the Bill. It is going to effect by legislation what has been nearly accomplished by the voluntary combination of the bodies. The Scotch amalgamated boards are doing as well as the Bill will compel them. The Irish and English are on the point of agreement to an amalgamated scheme when the Government steps in to order what is being really done. If legislation is to give us no more than the corporations are ready to offer, then let legislation leave us to arrange our matters with the corporations. Those which combine in a reasonable way will be supported by the masses of the Profession, and the obstinate ones will be left out in the cold, and soon must die of inanition.

Again, there is the vital defect of the Bill—the absence of any clause securing the representation of medical practitioners in the General Medical Council which is supported by money extracted from their pockets.

Nothing is more monstrous than that a dozen or a score of men should depute one of themselves to represent thousands of their brethren; yet this is the condition of things. At the Meeting of Fellows and Members of the College of Surgeons of England, as will be seen from our report, this subject continually recurred. The President himself spoke of it in a manner that will enhance his popularity. He may be looked upon as pledged to advocate the extension of the College franchise in this matter. Mr. Busk, indeed, spoke contemptuously of the agitation, and thereby sealed his fate for any future election—for one so completely out of tune with the progress of medical reform can have no right to assist in governing.

Mr. Christopher Heath put his finger on the blot in this matter when he said that after the President's speech it was known that the Council of the College, *without any need for hurry,* were about to hold a special meeting to depute one of their number to elect a representative for five years. He condemned this as a monstrous usurpation. We, knowing that there are members of that Council who hold our views, add our utter condemnation of the indecent haste thus displayed in the very act of usurpation: Why could it not be delayed?

Dr. Prosser James, who has done much work on this question, was present, and proposed an amendment which was evidently well received, but which he withdrew at the suggestion of those who supported it, in order that, if the Bill is to be imposed on the Profession against its will, there might at least appear unanimity as to the fact that Clause 18 is the only one of any value. In withdrawing it Dr. James appealed to the President to call together the Members and Fellows to discuss this question, and the appeal produced strong marks of approval. In fact Mr. Cock can hardly recede. He has entered on a course that will make his Presidency memorable—let him respond to that appeal and he will have the support of the whole mass of the Profession. And why could not the selection of a representative have been postponed till after such a meeting? It would be an honour to represent 17,000 Members and Fellows. It is a disgrace to usurp the rights of these, and the man who, being sent to the

General Council by the College Council, pretends to speak in the name of the whole body of Fellows and Members, lays himself open to the charge of being a rank impostor.

Mr. Christopher Heath spoke as a genuine reformer. A Fellow himself, he included Members as well as his own class, and thus adopted to the full extent the views so long advocated by Dr. Prosser James. These views have now also been adopted by the *Lancet;* several Councillors have given in their adhesion to them; and we hope they may be introduced into the Bill by the House of Commons.

POOR-LAW MEDICAL RELIEF.

A FEW months ago we had the painful duty of recording the death of a woman at Chesterfield during parturition, when several practitioners, called upon to attend her, refused, so that the unfortunate parturient, unassisted and neglected, was permitted to perish. We expressed our regret then that the relieving officer of the district did not supply an order for the parish doctor, as want of means to defray the midwifery fee must have been the cause of so many different medical gentlemen refusing. This week a provincial correspondent tells us of a somewhat similar case which occurred in his practice a few days ago, the facts of which are as follow:—A woman was seized with labour; her husband, an industrious man, owed a large bill to the parish doctor for attendance upon his family, which he was unable to settle. The doctor refused to attend unless the midwifery fee either was paid in advance or an order obtained from the relieving officer. This the latter refused, and the man was without money, so that before assistance could be obtained from another place the patient was well-nigh worn out. This brings us at once to the subject matter of a letter on this question lately addressed to us by Dr. Waring-Curran, wherein the writer forcibly calls for the abolition of the extra fee system as pertaining to Poor-law medical officers, for in the case of our correspondent, just cited, there would have been no difficulty in granting an order were it not that the relieving officer felt he was incurring a debt of ten shillings, which his masters—the gentlemen of the Board of Guardians—might seriously object to. Again, the difficulty about granting the order might have been overcome if *the loan system* advocated in our pages and elsewhere by Dr. Waring-Curran were adopted, whereby, in all cases in which doubt exists in the mind of the relieving officer respecting the circumstances of the applicant, the order could be given *on loan*, and on a future day the amount of fee and other expenses be recovered back again. Were this general, as Dr. Waring-Curran tells us, many would prepare to have the fee at such a time ready, since they could not "sponge" upon the parish authorities without being held liable in a court of law to refund the debt.

We have little doubt the *loan* system would work well. We know in those workhouses wherein tramps seek and obtain a night's lodging, with a breakfast the ensuing morning, and they are compelled to do a certain amount of work in return for it, that the vagrants, knowing the system, avoid the institution; so do we believe it would be with the pauper and the *loan* system. At all events, no woman, for the want of proper professional help in the hour of parturition, should be allowed to die. The parish doctor is very often imposed upon, and his post is one of great difficulty, which we see no way of remedying other than the constitution of a *special* Poor-law service, the abolition of the extra fee system—which we repeatedly find endangers human life in the time of suffering, because of a few paltry shillings being the question at stake—and the organisation of a *loan* system of relief. No doubt the latter would materially add to the responsibility and importance of the relieving officer's duties. "But let him," as Dr. Curran elsewhere suggested, "be paid extra for the work done according to the amount he annually saves the parish by the working of such a system."

Notes on Current Topics.

Dr. Henry Bennett on Midwives.

WE are quite of the opinion of Dr. Bennett, that the introduction of skilled women into the practice of midwifery would prove an immense boon to the more scientific practice of the healing art. The immense majority of cases of labour are weary affairs to the educated practitioner, and he feels almost in despair when he sees the weary hours glide away whilst attending on a straightforward case of labour at the waste of time it entails on him. Everyone who reads statistics knows that, probably on this very account, the most cases of death in labour occur in those countries where midwives do not usually attend labour cases. The practitioner, longing to be released from his weary watch, is tempted to have recourse to forceps to shorten the labour, and this is a very serious drawback to the utility of male accoucheurs. Let women, then, be admitted freely into the medical Profession, whether as physicians or midwives, and we are confident that the Profession will by no means lose in public estimation by the change.

Vaccination versus Variola.

THE Medical Department of the Privy Council appear at last to be doing their duty. As mentioned in our last, they have severely rebuked the Guardians of the Oldham Union for neglecting to comply with the Vaccination Act. Of course, they were awakened to a sense of duty by a severe epidemic of small-pox prevalent there. Recently, in the MEDICAL PRESS, we have directed, in very sharp language, the attention of the Privy Council to the fact of many Boards of Guardians ignoring the last Act and refusing to contract with their medical officers under it. Will every parish wait until small-pox invades them, and will the Privy Council rest with folded arms until death stares them in the face before the law is universally carried into force? Surely there must be lethargy and carelessness somewhere. If Boards of Guardians won't obey the law, why not make them, and hold them equally responsible with the parent who refuses or neglects to have his offspring vaccinated? When disease becomes epidemic, it is not the time to manifest the power of official life. If legislators consider certain codes of law necessary to be enacted, and create and pay certain functionaries for carrying them into effect, we hold that the latter are as much to blame as the miserly Board of Guardians, who dread a little extra expense being incurred, and that both are worse than the ignorant and negligent parent, who knows no better than to refuse having his child preserved against the ravages of so dire a disease as variola.

House Painting.

At this season of the year the physician not unfrequently has his attention directed to cases of insidious colic, which, upon enquiry, can be traced to living in a house recently painted, or occupying for sleeping a chamber whose wood-work is being improved by the hands of the painter. A word of warning is not, we conceive, out of place. Where white lead is being used, the greatest possible care should be exercised; upon some its trying and deleterious influence is resisted, whilst upon others of more delicate constitution, or possessed of an idiosyncrasy to the effects of lead, very grave consequences result, which provoke much suffering to the incautious and difficulty to the physician in eradicating the poison out of the system. There are some kinds of white lead paint used which dry very slowly, and when it does dry, rubs off in a white powder-like form if the temperature of the apartment be higher than ordinary. This is a very serious matter indeed to those occupying a house where such paint is employed. Lately we have visited several patients suffering from lead colic entirely dependent upon living in houses recently painted. We recommend, where it is possible, that the house should be vacated to the painter, and that all smell of paint should have gone off before re-inhabiting it; and when this is not feasible, we advise our patients, as preventative measures, to ventilate sufficiently, and use vinegar freely with their meat, and partake of salad prepared with vinegar. When the colic manifests itself, then, of course, we must adopt the usual remedies. But, as prevention is better than cure, we have no hesitation in remarking that many of the cases to which we were called might never have occurred had a little judicious care been exercised in guarding against the evils of freshly-laid-on white lead.

Hold! St. Pancras.

The "worm" is again busy amongst the Guardians of St. Pancras parish. This time the raid is upon the district medical officers—and why not? for, according to Guardian Salter's public statement, "the hall may be (at any time) filled by gentlemen," each of whom suffers a thirst insatiable for a *chance* to tilt from the parochial hobby-horse a professional brother, in order that he may bestride him.

At the present time, the parish of St. Pancras is divided into six medical districts. It is one of the largest parishes in the kingdom, its area being about twenty-one miles, and its population 250,000 souls; it is, in part, poor as Poplar or Bethnal Green, populous as St. Luke's, Whitechapel, or St. Giles's. The medical officer of each district receives an annual stipend of £150, together with a small fee for difficult obstetric cases, paid nurses being supplied by the Guardians to meet the requirements of the poor in ordinary cases of travail.

Now, "in the interests of the poor," the preposterous—if not really insane—proposition has been submitted to the Guardians, of reducing by one-third the district medical staff; that is, to place on the shoulders of four medical gentlemen duties heretofore more than ample for the correlative strength and endurance of six, aided too, in most cases, by energetic and fully qualified assistants. Let us hope the Guardians of St. Pancras parish will take a bird's-eye view of the parochial map ere this false step be made, for if the attempt be persisted in to lop off medical districts and to place this stupendous field of pauperism—which St. Pancras parish undoubtedly is—*without* the pale of medical aid, it shall be reprobated, as it so thoroughly deserves; for to all good men, and decidedly to us, as representing a large section of our medical brethren, the prolongation—even by a single hour—of the life of the most abject member of the great human family is more sacred, and far dearer, and more vitally important, than a knowledge of the triumph of cheese-paring economy, and of pompous parish *quidnuncs*.

Contagious Diseases Acts.

A large and enthusiastic meeting in favour of the repeal of these Acts was held on Wednesday last, 28th June, at the Beaumont Institution, Mile-end road. Sir George Grey, on taking the chair, said that it was time that something was done to alter the condition of our standing army, for whose sake such unconstitutional Acts had been framed. He mentioned that there were large numbers of troops in this country at present—some 95,000 men being within the precincts of the British Islands—almost all of whom were kept in a state of enforced celibacy. This should be altered as soon as possible, and there was no reason why soldiers' colonies might not be settled in some of our large open spaces, where soldiers might be allowed to marry like any of the rest of the male citizens of this country. Mr. E. Beales dwelt on the disgraceful injustice of Acts which permitted a woman, by the fiat of a policeman, to be put in prison, without trial, for a month, and allowed a medical man to imprison a girl for nine months, for the sake of the health of a celibate army. Dr. C. Drysdale objected to the civilian women of this country being placed yet more in the power of men than they are at present, for the sake of a celibate army. As to the idiotic idea of extending such Acts to the whole of this country, men who did so were utterly careless of the teaching of all countries where such Acts were enforced. In Paris, the amount of venereal contagion in all classes was larger than in any of our cities, the prostitutes were ruined for life, and the whole theory of honest love and affection between the sexes was destroyed by the police mouchards of Paris and elsewhere. He trusted that, instead of such Acts being carried here, the Acts of Paris might be repealed. Mrs. Law addressed the meeting, and Mr. Baxter Langley added some words. The meeting almost unanimously and enthusiastically voted for the repeal of the Acts.

We presume we have now heard the last of that execrable impostor, the *soi-disant* Dr. Newton, miracle worker from America. Like the Zouave Jacob, and others of similar notoriety, "every dog has his day"—so with this latest importation of impudence and falsehood, the populace will suffer him no longer, and at his last performance, at a Baptist chapel in Paddington, he was most unceremoniously mobbed, and it was only by his acrobatic accomplishments that he was enabled to escape the fury of the mob by scaling a garden wall—*for him a miracle*—as it saved him the chastisement, if not the Lynching, he so richly deserved. The Baptist minister, also, who pretended to be a believer, and who had lent his chapel to the fellow, did not altogether escape with that delicate treatment he might have desired. Give such men enough rope and they will soon hang themselves—particularly if the public are allowed to be the judges.

Hospital for Scrofulous Children.

The Department of Public Health of France has founded near Calais a sea-side hospital for the treatment of scrofulous children from Paris. In consequence of the success of the experiments undertaken in 1861, with an hospital of 100 beds, the department has provided accommodation somewhat in proportion to the wants of the Parisian population, and has caused an hospital of 500 beds to be erected. The Empress inaugurated it in last July. Desiring, however, to secure the benefit of sea-side treatment, not only for the destitute, but for the children of persons whose means would not allow them to incur the expense of a residence at the sea, the management has opened the small hospital to children whose expenses of maintenance (1f. 80c. per day) are paid.

Votes in Support of Homœopathy in America.

The *Albany Evening Journal* reports that one of the last acts of the American Legislature, at its recent session, was the passage of a law appropriating 150,000 dols. for a State Lunatic Asylum. The institution is to be known as the State Homœopathic Asylum for the Insane, and is to be conducted upon the homœopathic system of therapeutics.

Another law was also passed authorising the New York Sinking Fund Commissioners to lease, for four hundred years, suitable grounds in the city of New York for the Hahnemann Hospital. The terms of the lease provide for a nominal rental of twelve dollars per year (one dollar per lot), so long as the building is used solely for the purposes indicated in the Act. An appropriation of 20,000 dols. was made towards a building fund.

We find that the 200,000 dols. voted this year to homœopathic organisations is nearly one-third the total amount appropriated.

This is the first apportionment to State institutions under homœopathic auspices.

The annual meeting of the Lancashire and Cheshire Branch of the British Medical Association was held at Preston last week, when about eighty gentlemen were present. The following resolution, on the proposition of Mr. A. B. Steele, seconded by Dr. E. Waters, was carried: "That this meeting is of opinion that the powers given to the Privy Council by the amended Medical Act are excessive, and ought to be limited to the placing of a veto on the General Medical Council;" and it was also decided that a memorial embodying the resolution be forwarded to the Lord President of the Council and to the Houses of Parliament, signed by the President and Honorary Secretary.

It is announced that the office of editor of the *British Medical Journal* is about to become vacant by the resignation of Mr. Jonathan Hutchinson.

SCOTLAND.

GLASGOW.

Anderson's University.—The annual meeting of the trustees was held on Thursday. The number of students attending during the past session was 2,541. It was agreed to advertise for a successor to the late Dr. Penny in the chair of chemistry, and that, in electing, power should be reserved to the trustees to create any other chair or chairs in connection with the University. A motion was proposed and lost by a large majority, to remove the restriction which, by the will of the founder, limits the appointment of professors to the term of one year. The various professors were unanimously re-elected for a term of one year.

EDINBURGH.

The University Athletic Sports.—The fifth annual exhibition took place in Greenhill Park on Thursday last, and attracted a large number of spectators, the park presenting a most brilliant appearance. The prizes, which were distributed by Professor Turnor, were unusually numerous and valuable.

Dr. James Rutherford, of the Burgh Lunatic Asylum, Birmingham, has been elected medical superintendent of the Lochgilphead Asylum, in room of Dr. Sibbald, appointed Deputy Commissioner in Lunacy for Scotland.

Funeral of Professor Syme.—On Thursday afternoon, the body of Professor Syme was interred within the family vault of St. John's Episcopal Church. Although strictly private, it was striking to observe the spontaneous marks of respect which the occasion called forth. In the streets through which the procession passed the shops were closed, and the sorrow we heard expressed by all classes of persons indicated to us the deep love and respect in which the memory of that great man is held. The service in St. John's was conducted by the Venerable Dean Ramsay and the Rev. D. Sandford.

THE MEETING AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND ON THE MEDICAL BILL.

The Meeting of Fellows and Members mentioned in our last was held on the 28th ult.; the President, Mr. Edward Cock, in the chair.

In opening the proceedings, the President stated that he was himself responsible for convening the meeting, but he was sanctioned in the course he had taken by the two Vice-presidents of the College. It appeared to them to be so important that the opinion of the Fellows and Members of the College should be sent at once to the House of Lords that they did not wait to consult the Council. The Bill was no longer that which they had previously discussed, for the 18th Clause, enacting that the only portal to the Profession should be through the examination of a viz., the establishment of one uniform system of qualification and examination for admission to the Medical Profession, or, in other words, the establishment of the one portal system, is entirely abandoned.

That by the Bill as it at present stands the Medical Authorities will be enabled to confer as heretofore their several Degrees and Diplomas which—notwithstanding the provisions of the Penal Clause (Clause 21) of the Bill and notwithstanding that the possessors of such Degrees and Diplomas will not acquire any claim to registration under the Medical Act — will undeniably be qualifications to practise.

That the Bill in its present form is calculated to keep alive that competition amongst the Medical Authorities which it was one of its principal objects to abolish; for the General Medical Council, instead of being called upon only to supervise the examinations of the three Examining Boards to be established by the Bill, will have the impossible task of striving to secure uniformity in the examina-

conjoint board, and that no honours or degrees should be conferred until that portal was passed, had been abrogated. They considered that that abrogation really emasculated the Bill, and they therefore thought it right to summon the Fellows and Members of the College, in order that the subject might be fully considered.

Mr. Busk proposed—"That this meeting fully agrees with the opinion expressed in the resolution of the Council of the College on the 9th instant — namely, that the original Clause 18 of the Medical Act (1858) Amendment Bill should be reinserted in the Bill, and that a petition in the name of the Fellows and Members of this College, as represented by this meeting, be drawn up and presented to the House of Lords, praying that, for the reasons stated therein, the original Clause 18 may be restored to the Bill." The abrogation of Clause 18, instead of rendering the admission into the Profession more simple and uniform than at present, would, he believed, have the opposite effect; instead of nineteen portals to the Profession, there would in future be twenty-two. The alteration was said to be a concession to the Universities, but it was a well-known fact that scarcely any practitioner of medicine gained admission through the portals of the Universities. As far as England was concerned, the Profession at large consisted of members of the Colleges of Surgeons and Physicians and of the Apothecaries' Company. There were two other points in the Bill which required even more serious attention, but they could not then be discussed. One of these was the disproportionate representation of the medical corporations in the General Medical Council.

Mr. Partridge, in seconding the resolution, expressed his general concurrence in the remarks of Mr. Busk.

Mr. Gamgee, of Birmingham, thanked the President for convening the meeting. There could be no doubt, he said, that, in the opinion of the majority of the Profession, Clause 18 was the most important feature of the Bill. With regard to the question of representation in the Medical Council, the vast bulk of the Profession was undeniably not represented at all. He deeply regretted that this question could not be taken up.

Mr. Adams also suggested that the authorities of the College should prepare a Bill, and submit it to the Legislature for adoption.

Mr. Heckstall Smith said that nothing had given him so much surprise as the omission of Clause 18, which was the very essence of the Bill. He trusted that the Council of the College would give their strongest support to the restoration of Clause 18, and thus put a crown to their exertions of late years. Much as the members had had reason to complain of them in times past, there could be no doubt that they had of late been marching with the times.

Mr. Rogers Harrison congratulated the authorities of the College on the step they had taken in summoning the meeting, and expressed his concurrence with the resolution.

Mr. Christopher Heath said he was glad to hear Mr. Busk express an opinion that the corporations were inadequately represented on the Medical Council. It appeared to him somewhat strange that a member of the Council should express that opinion, when on the following Tuesday the Council would proceed to elect a representative of the College for the next five years. He protested that the election would be a usurpation of the rights and privileges of the Fellows and Members.

Mr. Gant said that the resolution, if it passed in the form proposed, might lead to the supposition that, on the restoration of Clause 18, the Fellows and Members of the College woud be perfectly satisfied with the Bill. He suggested a rider to the resolution, stating that no Bill would satisfy the just claims of the Fellows and Members of the College which did not distinctly provide for their direct representation in the Medical Council.

The President ruled that the regulations did not admit of a rider being added,

Mr. J. F. Clarke said that Clause 18 was the fundamental point of the Bill, and its omission was most disastrous. If the Bill passed without it the result would be like playing a game with loaded dice.

Mr. Busk differed from Mr. Heath in his view of the matter respecting the General Medical Council, and condemned the scheme for electing representatives in the Council from the general body of the Profession as utterly preposterous. He went on to say, amidst loud cries of dissent, that an immense deal of mischief had been done by the apparent antagonism of a certain part of the Profession towards the Council and the College.

Mr. Cooper expressed his hearty concurrence in the resolution proposed by Mr. Busk.

Dr. Prosser James thanked the President for summoning Members as well as Fellows to the meeting, but declared that the restoration of Clause 18 would not make the Bill worth passing. As the President had ruled that no rider could be added to the resolution, and as there was evidently a strong feeling on the point, he would move an amendment to the resolution of Mr. Busk in order to test the matter:—"That, while returning thanks to the President for petitioning the House for the restoration of Clause 18, this meeting is of opinion that even the restoration of the clause would not satisfy the Profession, and that no Bill would be of any use which does not provide for the representation of the Profession in the General Medical Council, and for one single examination entrance into the Profession."

Mr. Gant seconded the amendment, but subsequently stated that, desiring to have an unanimous expression of opinion with reference to Clause 18, he would recommend the withdrawal of the amendment.

Dr. Prosser James, in consenting to withdraw the amendment, said he hoped the President would fully consider the other questions, and, acting in the same manner as on this occasion, summon another meeting to discuss the whole subject of medical reform in that College.

A petition to the House of Lords, praying for the restoration of Clause 18, and specifying the reasons for such restoration, was then read and agreed to.

RESOLUTIONS—

That this Meeting fully agrees with the opinion expressed in the Resolution of the Council of the College of the 9th instant—viz., that the original Clause 18 of the Medical Act (1858) Amendment Bill should be reinserted in that Bill;

And that a Petition, in the name of the Fellows and Members of this College, as represented by this Meeting, and to the following effect, be drawn up and presented to the House of Lords, praying that, for the reasons stated therein, the original Clause 18 may be restored to the Bill, viz.:—

Unto the Right Honourable the Lords Spiritual and Temporal of the United Kingdom of Great Britain and Ireland in Parliament Assembled:

THE PETITION OF THE FELLOWS AND MEMBERS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND,

Humbly sheweth—

That whereas in a Bill introduced into your Honourable House, entitled "An Act to amend the Law relating to the Qualification of Practitioners in Medicine and Surgery, and otherwise to amend the Medical Act, 1858," it was originally proposed, by Clause 18 thereof, that the Medical Authorities described in Schedule 2 to the Bill should not in future confer any of the Qualifications mentioned in Schedule A to the Medical Act of 1858 except to persons who had obtained the Licence to practise under the provisions of the Bill, and whereas in the Bill as "Amended on Report" such Clause 18 has been struck out, your Petitioners beg to express their regret at the omission of the said Clause 18, and pray that, for the following reasons, the same may be restored to the Bill, viz.:—

That, by its omission, the main principle of the Bill,

tions of the nineteen Medical Authorities as well as in those of the three Boards.

That if the omission of the Clause be, as it is understood to be, a concession to certain Universities on the ground that some few persons seek to obtain the Degrees in Medicine of those Universities without any intention of practising the Profession of Medicine, and that it would be unfair to such persons to require them to pass the examinations of the conjoint Boards, such concession is totally uncalled for, inasmuch as it would be in effect making the interests of the Profession and the public at large, which can only be thoroughly secured by the adoption of the one portal system, subservient to the interests of a few individuals.

That a Degree in Medicine is, or should be, a test of the qualification of its possessor to practise medicine, whatever may be his ulterior motives in taking it, and that it cannot be considered any hardship upon the few individuals in question to require them to pass the examinations of the conjoint Boards.

That, moreover, it is competent for those persons who are desirous of devoting themselves to Science and to Literature, to obtain from the Universities Degrees, other than Medical, in evidence of their scientific acquirements and learning.

That, for the foregoing reasons, your Petitioners humbly pray that your Honourable House will consent to the restoration of the original Clause 18 to the Bill, or that your Lordships will refuse to give your sanction to the Bill; and your Petitioners, as in duty bound, will ever pray.

Signed on behalf of the Fellows and Members of the Royal College of Surgeons of England, assembled in the Hall of the College, this 28th day of June, 1870.

EDWARD COCK, President.

Mr. Spencer Wells proposed, and Mr. Gamgee seconded, a vote of thanks to the President, which was carried unanimously.

Correspondence.

MERCURY AND IODIDE OF POTASSIUM IN SYPHILIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In an interesting report of the Manchester Lock Hospital, by Dr. Charles Fryer, contained in your issue of the 22nd June, that gentleman relates the case of a man who had, during a history of syphilis of fourteen years' duration, taken much mercury, and had lost the whole of the soft and much of the hard palate. This patient was treated by chlorate of potash, oleum morrhuæ and good diet, without benefit; but was quickly cured by doses of iodide of potassium. Although deeply convinced of the injurious effects of mercurial treatment in this deplorable disease, I wish to express my opinion, firstly, that syphilis of itself is quite capable of destroying the soft and hard palate and the nasal bones, although it is, I conceive, far more likely to do so if mercury is poured in, as some rash elderly practitioners still seem to do. Younger men, I think, now know better things. I am, however, anxious to add that, in the case alluded to, as in all cases of those terrible sore throats with which we are so familiar in hospitals in London, the exhibition of large doses of iodide of potassium, fifteen grains thrice daily, has, in all cases I have yet seen, effected a speedy cure, where the fauces have been affected or the delicate nasal bones, or the patient was not dying.

Dr. M'Call Anderson seems to think (in a communication to one of your respected contemporaries) that, "if there is any tendency to syphilitic disease of the nostrils or neighbouring parts, iodide of potassium should be withheld, or given with great caution, for, if it produces coryza, it is very apt to aggravate the morbid condition of the parts." I cannot at all coincide with this opinion, as I have found that, in ozæna, the only mode of attacking the fœtor and specific inflammation is the exhibition of large doses of the iodide.

Dr. Anderson is much in favour of mercury—1, in infantile syphilis; but the cases given a few years ago by Allingham and R. W. Dunn, of such infants treated without mercury, showed a much better result than the mercurial treatment did; and Boeck, of Norway, in his "Recherches sur la Syphilis," gives many cases which were treated by this drug, and a great proportion of which died. 2, Mr. Gascoyen's cases of *syphilitic iritis*, treated without the use of calomel, added but to the testimony of Boeck, Taylor of Boston, and many others, that mercury was of no use in this affection. With regard to syphilitic skin affections and cachexia, the use of iodide of potassium in ten-grain doses is, in my humble opinion, far preferable to any other remedy. In short, before iodide of potassium was used, syphilis was confessed by all to be, in many instances, quite untractable; since the days of large doses of the drug it can be almost always kept in check, although, unfortunately, not cured.

I remain, Sir, yours faithfully,

CHARLES DRYSDALE, M.D.,
M.R.C.P.L., F.R.C.S.E.

99 Southampton row, W.C., London.

TREATMENT OF CARDIAC DROPSY BY STRYCHNINE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Recent experiments by a French savant have shown that merely ligaturing the main vein of a limb will not produce œdema, but if the principal *nerve* be cut after deligation of the vein, œdema at once supervenes. Now patients often suffer for a long time from heart-disease, attended with venous obstruction, without anasarca occurring. The experiment alluded to suggests the idea that, in such cases, a lack of innervation allows the dropsy to manifest itself, and that good therapeutical results might be obtained, either by exhibiting strychnine or phosphorus, the employment of galvanism, &c.; or, on the other hand, of ergot and belladonna, if the arrest of nervous influence be supposed to be due to congestion of the spinal cord. Of course I should not recommend any one to neglect the ordinary remedies found useful in cardiac dropsy; but they too often fail, or are inapplicable to the individual case. I ought not perhaps to take up your space with a mere theory unsupported by experiment, but the only case of anasarca I have met with since I read of the Frenchman's experiments, is one of *renal* dropsy with dilatation of the ventricle, which I am treating simply by jalap and vapour baths. There being a retained secretion in the blood and altered density of that fluid in renal disease interfering with endosmose I did not think it a case so likely to benefit by neurotonics as one of pure cardiac dropsy; but the latter disease is only too common, and some of your readers may be tempted to try one or other of the remedies I suggest, and record their experiences.

FRANCIS M. LUTHER, M.D.

Cappoquin, June 23, 1870.

ALLEGED RAPE BY A SURGEON.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I think I have seldom witnessed a thing more painful than a trial at the Old Bailey this week of a young surgeon on the charge of alleged rape of an aggravated form on a hysterical emotional girl, his character and practice ruined, the life or happiness of himself, wife, and family, cast on the hazard of a die, whether he should be found guilty or not, and sentenced to seven years' transportation, his actual crime having been simply and in reality that of using the ordinary vaginal speculum, as it was supposed, under some noxious drug (chloroform, of course), the poor young woman from emotion having fainted during the common use of the common speculum, and mistaking it for the alleged crime. I admired the charge of the judge very much, who saved him from the half-expressed mockings of barristers and doctors. The case is a frightful lesson for medical men, with the present popular notions that exist about the rapid action of chloroform, the whole of this supposed occurrence having taken up only about ten

or twelve minutes, and the police authorities supposing innocently enough that chloroform smelled out of a common Preston salts bottle renders the person insensible with the quickness of lightning!—the surgeon's assistant swearing positively it was a Preston salts bottle, with smelling salts in it, nothing more, the actual bottle given to the police, and yet a jury were divided equally, it was said, and took two hours to consider their verdict, after seven hours' trial. Added to all this, the fact that the father of the young woman was in the outside surgery waiting for the opinion of the surgeon till he had examined the girl, one room twelve feet square, the other about twenty feet. I believe there was no chloroform used at all; but there, standing alongside the Chelsea murderer in the dock, with a mocking crowded court, full of the unpleasant trial of the men in women's petticoats—deserted, I may say, by the Profession, stood this unhappy young man to take his trial.

I am, &c.,

Sackville street, June 10. CHAS. KIDD, M.D.

EDINBURGH UNIVERSITY.

By telegram we learn that Dr. Alexander Simpson, nephew of the late Sir J. Y. Simpson, has been elected to the vacant Chair of Midwifery by a majority of one. The other candidates were Dr. Matthews Duncan and Dr. Keiller.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

DR. M'SWINEY'S APEEAL.

THE Right Hon. the Lord Chancellor, the Lord Chief Justice of the Queen's Bench, the Chief Justice of Common Pleas, and the Lord Chief Baron, visitors of the King and Queen's College of Physicians, sat in the Court of Chancery, to deliver judgment on the appeal made by Dr. M'Swiney from a decision of a board of the institution. It will be recollected that the appeal arose from Dr. M'Swiney's rejection, when he became a candidate for the Fellowship of the College, on a vote by ballot. The system of vote by ballot had long been in use in the College, and the rule under which the election in question was conducted was a by-law passed by the board in 1862, providing that one black bean in five should exclude the candidate. According to this by-law, Dr. M'Swiney failed in his candidature, though a majority of the voters were in his favour. The petition to the visitors prayed that the by-law of 1862 might be declared illegal, and inconsistent with the College charter.

The LORD CHANCELLOR first delivered judgment, holding that the by-law of 1862 was illegal, and inconsistent with the charter, and that the petitioner ought to be indemnified as to his costs out of the funds of the College. His lordship said that, if the election had been by open vote, Dr. M'Swiney would have been duly elected; but, as the mode of election was illegal, there should be a new one.

The LORD CHIEF JUSTICE next delivered judgment. In doing so, he concurred with the Lord Chancellor. Having referred to the various authorities which had been quoted by counsel, he referred to the judgments of Lord Eldon and Lord Mansfield on similar cases. Lord Mansfield, when he gave judgment on the subject, said—"There can be little doubt (this is certainly my opinion) that the College are obliged, in conformity, with the trust and confidence placed in them by the Crown and the public, to admit all that are fit, and to reject all that are unfit." Lord Mansfield also said that the duty of determining as to the fitness of candidates belonged to the College of Physicians, and would not be taken from them by the Court; but that "their conduct in the exercise of this trust, thus committed to them, ought to be fair, candid, and unprejudiced, not arbitrary, capricious, or biased, much less warped by resentment or personal dislike." He (the Lord Chief Justice) would wish to ask this question—During the recent elections for Fellowships in our national University, where the fortunes for life of the gentlemen who became candidates were at stake, what would be said of the learned and esteemed man at the head of that University, or the distinguished men who assisted him, if, instead of giving their voice to the man who, by his learning and study, was qualified for the position, he should be elected or rejected by caprice, or without just cause? It was curious to observe, in the papers of the College, an entry of a resolution proposed on the 8th of November, 1853, by Dr. Frances, and seconded by Dr. Smith—"That all elections shall be decided by open voting, or by voting papers subscribed with the name of the voter." On a division, there appeared upon the minutes—Ayes, 3; Noes, 4; and the motion was negatived. There were 15 present at this meeting, so that there must have been 8 who expressed no opinion as to whether elections should be by ballot or not. He found that, on the 2nd of October, 1869, notice was given by Dr. Evory Kennedy that he would move that the opinion of the law officers of the Crown should be taken as to whether the by-law of 1862 should be rescinded. The motion was brought forward and summarily negatived. It was subsequently proposed by Dr. Lyons, and seconded by Dr. Evory Kennedy, that the opinion of the law officers should be taken on the charter and Acts of Parliament, with reference to the system of election by ballot. This motion also was negatived; though, in his opinion, no more reasonable proposal could be made. Then they had the evidence of Sir Dominic Corrigan that, at a meeting held on the 7th of April 1868, twenty-seven members being present, Dr. Haughton expressed his opinion that "the by-law was illegal." The election at which the petitioner was rejected was on the 18th October, 1869; therefore, the college had abundant notice that the validity of the by-law was a point which would be disputed. Notwithstanding, they refused to be advised with respect to it. He had no doubt that they thought they were acting under the charter; but they were the authors of the by-law, which was illegal, and he thought they should, in fairness, pay the costs of the petition.

The LORD CHANCELLOR said it was to be understood that the costs were to be "indemnified" out of the funds of the College. The Court of Appeal itself was, indeed, under great obligations to the gentlemen who acted as a committee on both sides, who had taken great trouble, and had given the court great assistance in the matter.

Chief-Justice MONAHAN said no person could for one moment suppose that it was consistent with the charter to allow a minority of four to govern the decision of a majority of three times four. So far as he was individually concerned, he was not of opinion that election by ballot was in all cases invalid or void. He had examined the charter of the College of Physicians in London, which was altogether silent as to how elections were to take place. But in the particular charter now before them, having regard to the 13th and 15th sections, which directed the election to be conducted in the College Hall, by "voice," and that, in the event of an equality of voices, the President or Vice-President was to have a casting voice, he conceived that the spirit of the instrument was utterly inconsistent with voting by ballot, because it would take away the power of voting by ballot from the president, who must, in the event of an equality of votes, give his vote publicly for the person whom he supposed to have been elected. Therefore, he had no difficulty in concurring with the judgment which had been arrived at by the Lord Chancellor and the Lord Chief Justice. It appeared that, if they had come to the conclusion that vote by ballot was legal, they must also have declared Dr. M'Swiney duly elected; but, as the mode of election was illegal, he could not be declared a Fellow without a new election.

The LORD CHIEF BARON also concurred in the judgment already delivered.

The Government Medical Bill.—This measure passed the third reading in the House of Lords on Monday night. An amendment by the Earl of Lichfield for the insertion in the Bill of a new clause providing that the General Council should always contain four representatives elected by registered members of the Profession in Scotland, and two other representatives elected by those in Ireland, was negatived.

NOTICES TO CORRESPONDENTS.

To Members of the Irish Medical Association.—The postal regulation, which forbids us to issue more than one supplement to the Medical Press and Circular, compels us to forego the publication of the *Journal of the Irish Medical Association* (weekly supplement to the Medical Press) this week, in favour of our half-yearly index. The matter for it is in type, and it will appear as usual next week.

"DOCTORS AND WATER DRINKERS," AND *WATER THINKERS.*

To the Editor of "The Medical Press and Circular."

Sir,—Knowing that your valuable journal is the only one our Profession possesses conducted on independent principles, and unassociated with any clique, will you allow me, with your well-known kindness, space to make a few remarks on a subject which needs nipping in the bud.

I am a member of a certain association that publishes weekly a scientific journal connected with it. Now I notice this day a letter which I think should never have been published on the subject of "Doctors and Water Drinkers," by an unprofessional gentleman, distinguished in Dublin for being a vegetarian, a teetotaller, and a lecturer at piety teagatherings, who, forsooth, reads us a lecture on the treatment of disease! I object myself, and so do the Profession as a body, being dictated to by people who know nothing about the intricacies of what they write—superficial observers and shallow-minded thinkers. To be told by a non-medical man in the columns of a medical journal "That medicine is not an exact science, *it does not prescribe any sure and universal remedies*," and a lot of other bosh—a direct insult to the man of science—is unpardonable.

Surely when we are being dictated to, and taught practical lessons in the science and art of medicine by outsiders, and medical journalists are found ready to open their columns to a page of utter nonsense, which every practical man knows it to be, it is not to be wondered at that we feel humiliated and disgusted at times. To argue the question of total abstinence with a teetotaller is beneath me, for I know, and so do all, that, in the treatment of disease, alcohol is indispensable. At the present moment I don't know whether to feel more angry at the self-sufficiency of those who have no right to dictate to our Profession, or with the managers of a journal who print so much rubbish.

Your obedient servant,
A Member of the British Medical Association.

June 25th, 1870.

BRITISH MEDICAL ASSOCIATION.

To the Editor of "The Medical Press and Circular."

Sir,—Again I find we require a new editor for the journal of the Association. Indeed, I always felt Mr. J. Hutchinson could not conveniently spare the time for office work, owing to the varied and important duties he has to perform as a leading London surgeon. Will you allow me, in your independent and impartial columns, to inquire why it is the great body of members of the Association have no voice in its working, and that the choice of an editor is confined to the hands of a few? No doubt since Mr. Ernest Hart has returned to town, he will re-apply for the appointment; but I do very seriously object that the great body of members who are the mainspring of the Association have no influence or power in the management of it, or in the appointment of its officers.

Your obedient servant,
July 2nd, 1870. A Member of the Association.

MEDICAL CERTIFICATES FOR HOSPITALS.—VENTNOR.

To the Editor of "The Medical Press and Circular."

Sir,—Your *judicious* philippic on the very *injudicious* (to put it mildly) style of the Ventnor Cottage Hospital Certificate, deserves the thanks of the Profession. Recently, a form of certificate, precisely similar to that copied by you, was submitted to me by a *patient*, in order that I might fill in and sign it. I did neither. The medical committee of this Ventnor *Squat* Hospital are much to blame. The medical committees of many kindred institutions are much to blame also. This Ventnor Certificate exposure, let us hope, may cause them to re-consider the objectionable forms of certificates now in general circulation. The wording of most of these forms of certificates is for many reasons, absurd and vicious.

Yours truly, Anti-Humbug.

Marriages.

Bond—Hayes.—On the 28th ult., at Christ Church, London, Thomas Bond, F.R.C.S., to Rosa Sophia, third daughter of the late Mr. Justice Hayes.

Tayler—Hicks.—On the 25th ult., at St. John's Church, Lewisham, Francis Thomas Tayler, B.A., M.B., eldest son of Caleb Tayler, M.D., to Mary Ann, eldest daughter of Edward Samuel Hicks, Esq., of Rupert Villa, Lewisham.

Deaths.

Clark.—On the 29th ult., Sir James Clark, Bart., M.D., F.R.S., Physician to Her Majesty the Queen, aged 82.

Donnall.—On the 10th ult., at Westow road, Bath, Orlando S. Donnall, M.R.C.S.E., Deputy Inspector-General of Hospitals.

Fox.—On the 28th ult., at Brislington, Charles J. Fox, M.D., of Torquay, aged 64.

Lawrie.—On the 19th of April, at Ballarat, Australia, J. T. Brudenell Lawrie, M.D., aged 28.

Speer.—On July 1st, at 20 Falkland street, Liverpool, in her 27th year, Jane Kenyon, the beloved wife of Dr. J. Speer.

APOTHECARIES' HALL, BLACKFRIARS.

THE next EXAMINATION in ARTS will be held at the Hall on FRIDAY and SATURDAY, SEPT. 23rd and 24th, 1870.

A Syllabus of the Subjects for Examination may be had on application.

An Examination in Arts will again be held in the month of January, 1871.

R. H. ROBERTSON, Secretary to the Board.

IRISH MEDICAL ASSOCIATION.

AT the Annual Meeting of the Association held on the 6th June, the following Office-Bearers were elected for the year 1870.

PRESIDENT—Thomas Darby, Esq., M.D., Bray.

VICE-PRESIDENTS.

Dr. Beatty, Dublin.

Dr. Benson, Dublin.	Dr. Macnamara, Dublin.
Dr. Harvey, Cork.	Dr. Martin, Portlaw.
Dr. Hynes, Galway.	Dr. Walsh, A. J., Dublin.

CHAIRMAN OF THE COUNCIL.

William Jameson, Esq., M.S., F.R.C.S.I., Dublin.

COUNCIL.

Dr. Brassington, Rathmines.	Dr. Ledwith, Kingstown.
Dr. Chaplin, Kildare.	Dr. Mapother, Dublin.
Dr. Chapman, Donnybrook.	Dr. Maunsell, Dublin.
Dr. Churchill, Dublin.	Dr. Minchin, Dublin.
Dr. Darley, Coolock.	Dr. Morgan, Dublin.
Dr. Davys, Swords.	Dr. Morrogh, Dublin.
Dr. Faussett, Clontarf.	Dr. Porter, Dublin.
Dr. Hasler, Killiney.	Dr. Seward, Templeogue.
Dr. Jacob, A. H., Dublin.	Dr. Smith, Donoughmore.
Dr. Tuffnell, Dublin.	Dr. Wharton, Dublin.
Dr. Labatt, Dublin.	

Together with the Presidents, Vice-Presidents, and Secretaries of the Provincial Associations.

SECRETARY AND TREASURER.

E. J. Quinan, Esq., M.D., 29 Lower Leeson Street.

COLLECTOR.

Mr. John Maclean, Royal College of Surgeons.

N.B.—The Council meets upon the Second Thursday in each Month at 4 o'clock.

The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 13, 1870.

Original Communications.

ON THE PROSPECTS OF THE SEWAGE QUESTION.

By Henry Letheby, M.B., &c.,

Professor of Chemistry at the London Hospital Medical College, Medical Officer of Health to the City of London, &c.

(Continued from Page 3.)

The other means of dealing with sewage, so as to separate the suspended matters, and to remove a certain portion of those which are dissolved, is to submit it to chemical treatment. Already there are sufficient facts to enable us to review this part of the subject.

At Leicester, at Hertford, and formerly at Tottenham, the sewage was defecated with lime, the lime being used to the extent of from 5 to 20 grs. per gallon of sewage. The treatment is effected by adding the lime to the sewage, and then briskly agitating it; after which it flows into subsiding tanks, where the sedimentary matters deposit, and the clear supernatant water runs off by a weir placed a little below the surface. At Hertford the supernatant water is filtered before it is discharged into the outfall, and in summer time a little chloride of lime, amounting to about half a grain per gallon of sewage, is also employed, as it is found to deodorize the sewage, to check secondary putrefaction, and to prevent the growth of the sewer fungus in the outfall channel. In the year 1858, when I first examined this process at Leicester and Tottenham, for Messrs. Bidder, Hawksley, and Bazalgette, the referees appointed by the Metropolitan Board of Works to consider the question of the main drainage of the metropolis, I found that with 12 grs. of lime per gallon of sewage the whole, or nearly the whole, of the suspended matters were removed, and that the soluble organic matter fell from 13½ grs. per gallon to 10½ grs. When 20 grs. of lime were used, the soluble organic matter fell to about 9 grs. On the occasion of a more recent visit to Leicester, with Dr. Frankland and Dr. Odling, at the instance of the Thames Conservancy Board, we found that the soluble matters of the sewage were reduced from 63 grs. per gallon to 48 grs. —the organic matter falling from 15 grs. to 5 grs. At Hertford, where the original sewage is remarkably weak on account of subsoil water, I have ascertained from many experiments that the organic matter in solution is reduced from about 3 grs. per gallon to 1·6 gr. All these results accord well with laboratory experiments, and they show, as I stated in my original report to the referees alluded to, that, "judging from the experiments which I have made, and the observations of practice on a large scale, it is ascertained that about 12 grs. of lime to a gallon of sewage will effect the speedy separation of all the suspended matters, and also about one-fourth of the dissolved organic matter, leaving a clear liquor which has lost a great part of its offensive odour; and when the clear liquor is mixed with from five to seven times its bulk of water, and is exposed to the air, it is no longer offensive."

'At Leicester, where the lime process has been adopted, the river Soar, into which the sewage flows, has undergone a remarkable improvement. Before the works were established the river was most offensive, the fish were killed, the vegetation of the river was destroyed, and those who inhaled the effluvia from it were constantly ill. At the Belgrave mill, which is just below the point where the sewage enters the river, the foulness of the stream was such that in summer time the water of the mill-dam appeared to boil with putrefaction; the stench from it was intolerable, and so large was the quantity of sulphuretted hydrogen evolved, that the silver in the men's pockets turned black in a few hours. At that time the men were constantly affected with diarrhœa, they lost their strength, and their appetites always failed them; one man only out of thirty men in eighteen years had been able to stand it, and he it was who gave me an account of the matter. Now, however, and for the last three years since the lime process has been adopted, the river presents an entirely different appearance—aquatic plants have begun to flourish, the fish have ventured to return, the black mud has ceased to accumulate, and the mill-dam is no longer offensive. All along the stream the people speak of the change with satisfaction, and it would appear that the process fulfils

the requirement of the local Act, which demands that the water discharged from the local works shall not occasion a nuisance, or be injurious to the health of those who live or are employed on the banks of the stream."

Crude sulphate of alumina is another precipitating agent. It is practised at Stroud in Gloucestershire, and is known as Bird's process. The crude sulphate is made by adding about 20 lbs. of sulphuric acid to a hundredweight of powdered clay, and allowing it to stand for some time. This material is mixed with sewage in the proportion of one hundredweight to from 20,000 to 30,000 gallons of sewage, and the sedimentary matters are collected in a properly constructed tank. Sulphate of alumina is decomposed by the ammonia of the sewage, and the alumina flocculates and precipitates the suspended matters, leaving a clear supernatant liquid, from which a good deal of dissolved organic matter has been removed.

To ensure the precipitation of the alumina, Dr. Anderson, of Coventry, recommends the addition of lime. Crude sulphate is made by adding one part of sulphuric acid to two of clay, and then two parts of water. After standing for some time in a warm place the combination of the acid with the alumina is effected, and he uses about one pound of this material to every 100 gallons of sewage. The mixture is well agitated, and then a quarter of a pound of lime in a creamy condition is added. Again it is agitated, and the flocculent alumina, together with the suspended matters, rapidly falls. The sediment is collected in subsiding tanks, which are worked alternately, and the clear liquor is run off from it. As in the last case the suspended matters are entirely removed, with a considerable amount of the dissolved organic matter.

Chloride of iron, with lime, is also a powerful defæcator. It was formerly used at Northampton, and is still to some extent with lime—the lime being first added to the sewage in the proportion of about a bushel to 8,590 gallons of sewage, and the chloride of lime to the extent of about half a gallon. The chloride is made at the works, and contains about 9,500 grs. of the mixed chlorides of iron per gallon. In this case also the precipitation of the sewage is very complete. At present, however, the local authorities are using sulphate of iron and alumina instead of the chloride. The compound is made by mixing 3 cwts. of crude sulphuric acid with 2 tons of a ferruginous earth obtained in the neighbourhood. After standing for a few days the mixture is ready for use, and it is added to the sewage in the above proportion to a million gallons of sewage.

At Leamington, where there is an injunction against the discharge of unpurified sewage into the river Leam, the authorities have resorted to the use of the "A. B C." process of Mr. Sillar, which is worked by the Native Guano Company at its own cost. The sewage flows to the works by gravitation, and there it is mixed with the A. B. C. material (consisting of alum, clay, sulphate of magnesia, bone ashes, wood charcoal, and a little blood diffused through water). The material is added to the sewage in the proportion of 1 gallon to 200 gallons of sewage, and the whole of it well agitated. It then flows through subsiding tanks, where the precipitated matters subside, and the clear water flows off from a weir into an outfall channel with a filter. The tanks are worked continuously for about a week, when the precipitated matter is removed to a centrifugal machine, and drained to the consistence of putty. This is further dried by exposure to the air, and its ammonia is fixed by means of a little sulphuric acid, which also breaks up the organic matter. In this state it is riddled, and sold freely at a good profit for manure.

Samples of the Leamington sewage were taken for examination by the Royal Pollution Commissioners on the 11th of December last, and duplicates of them were furnished to me on the following day for analysis. I ascertained that the original sewage contained 66 grs. of solid matter in solution per gallon, of which 14·91 grs. were organic, while the effluent water before filtration contained 67 grs. of soluble matter per gallon, of which 11·21 grs. were organic; and the filtered water contained 61 grs. per gallon, of which 6·3 grs. were organic sewage, the suspended matters in the original sewage amounted to 3·16 grs. per gallon, while in the effluent sewage before filtration it was 7·61 grs., and in the filtered sewage, 3·12 grs. The Royal Commissioners, in describing their results, do not mention the filtered water, but in other respects their results accord pretty closely to mine.

Lastly, there is a process of the late Mr. Blyth, which is very deserving of attention. Mr. Blyth was the chemist of the old Board of Health, and he had great opportunities of studying this matter. His plan is first to add a soluble phosphate of lime and sulphate of magnesia to the sewage. After agitation, the mixture is neutralized by means of a little slaked lime, and the precipitated magnesian phosphate carries down with it the whole of the sedimentary matter, and a portion of the soluble ammonia. A million tons of sewage require about 1 ton 3 cwts. of Blyth's compound and 4 cwts. of lime to neutralize, and the resulting dry precipitate weighs about 3 tons 8 cwts., and contains about 58 per cent. of organic matter (yielding 4·5 ammonia), and 8·66 of phosphate of lime.

All these processes are manifestly capable of separating from sewage all the sedimentary matter, and also of removing considerable portions of dissolved organic matter; but to be effective there should not only be good agitation of the sewage after the addition of the precipitating agent, but there should also be sufficient tank-room for the deposition of the sewage for not less than four hours; and there should also be a means of filtering the defæcated sewage before it is discharged into the river or other watercourse.

After witnessing the action of lime as a defæcator, at Leicester and Hertford, Dr. Odling, Dr. Frankland, and myself reported to the Thames Conservancy that the following were the conditions necessary to its success:—

1. The proportion of lime should not be less than one ton to a million gallons of sewage, and that there should also be used 56 lbs. of choride of lime.

2. That the mixture of the sewage with the lime and chloride of lime should be very complete, and that the mixture should be agitated, so as to aggregate the suspended matters, and thus assist in the subsequent precipitation of suspended matter.

3. That the sewage when thus treated with lime should flow along two subsiding tanks in series; the first should be capable of holding at least one hour's flow, and the second of holding not less than four hours' flow. The tanks should be four feet in depth, and the overflow of the defæcated sewage should be by a weir only half an inch below the surface.

4. That there should be a double set of tanks for alternate working.

5. That the defæcated water should flow through a shallow open conduit of not less than a quarter of a mile in length before being received into a stream of freely running water, of not less than eight or ten times the volume of the defæcated sewage.

In this way, or by any similar process of defæcation, the sewage of towns may be easily and safely dealt with, so as, on the one hand, to ensure its purification before it is discharged into a running stream, and, on the other, to avoid the many dangers of irrigation.

I refrain from entering on the subject of the pecuniary aspects of this question, for they are nowhere encouraging notwithstanding that the most sanguine opinions have been expressed of the commercial and agricultural value of sewage. Irrigation, like precipitation, except in the case of the Leamington process, is everywhere unprofitable, when it is conducted in such a manner as to prevent the pollution of the neighbouring streams; and I warn you against the glowing accounts which are given of the profitable returns of certain sewage farms, for, if the cost of outlay is considered and balanced with the average returns, it will always be found to be a losing affair. The most sanguine enthusiasts of the system have generally abandoned it after a trial of its merits. Little or nothing, in

fact, can be profitably grown upon the sodden land but Italian rye-grass, and when this is abundant and must be cut, or it will rot upon the ground, it must be sold for what it will fetch. In the summer of 1866, when I was in Edinburgh, I saw acres upon acres of rye-grass rotting upon the far-famed Craigintinny meadows; and when I asked the cause of it I was told by the manager that the cattle plague had ruined his customers, and there was nobody to buy it and nothing to eat it, and there it must rot. Besides which there are considerable doubts as to the value of it as fodder. Mr. Campbell, of Rugby, who ought to be a high authority on the subject, for it was a pet of his, honestly declares that his experience does not show a profit in the use of such fodder, and he gives a good example of it. Twelve Ayrshire cows, which calved about the same time, in May, 1869, yielded, at the end of twelve weeks, an average quantity of 9½ quarts of milk per day per cow. Their daily consumption of rye-grass was 1½ cwt per cow. If they had been milked for nine months the average daily yield of milk would have been only from 5 to 6 quarts per cow. The cost of the grass at 10s. a ton, was 9d. per cow per day, and the other expenses of the dairy raised it to 1s. 3½d. per cow. The milk, at 8d. per gallon, was worth only 1s. 7d.; and when the cost of sending it to market was taken into account, together with the wear and tear of utensils, he vainly asked for profit.

But all this is, as I have said, no part of my present inquiry, for my business is solely with the sanitary part of the question; and I would ask you whether, having regard for the public health, there are not serious dangers in the rash recommendations of the Royal Pollution Commissioners to scatter the sewage of every city and town in the kingdom broadcast upon the land? Medical authorities of some sanitary experience are alone able to engage in such important pathological considerations, and it must strike every one who is interested in the subject that a Royal Commission without any pretence of medical knowledge is singularly incompetent to deal with such a matter. What importance the public or Parliament may attach to their recommendations I am unable to learn, except from former experience, but it is clearly our duty as public health officers to examine the subject from a medical point of view, and I doubt not what will be the conclusion.

ON THE INCUBATION PERIOD OF TRUE SYPHILIS.

By Henry MacCormac, M.D., Belfast.

A very safe rule to adopt with regard to the statements of venereal patients, is to maintain a prudent scepticism as to everything they may allege concerning their ailments. Their well-known want of veracity and the inherent difficulties of the subject involve in much obscurity the investigation of venereal diseases. Every well-authenticated fact which can be deprived of the many elements of doubt which enshroud these cases, becomes of importance; and I therefore venture to place on record two cases confirmatory of a certain doctrinal point—the period of incubation of true syphilis. By this I mean the interval of time which elapses between the impure connection, the source of the disease, and the first manifestation of a local lesion. The doctrine of a period of incubation in syphilis was first propounded by Alphonse Cazenave, in 1843, and is, as yet, by no means generally admitted by medical men, although the opinion is now adopted by most eminent syphilographers. In the two cases, whose particulars I wish to relate, I believe I may rely with perfect certainty that a truthful tale has been told by each individual, and that the facts are precisely as they have been related to me.

Case I.—A policeman, æt. 21, previously to this illness in the enjoyment of perfect health, was admitted to hospital under my care suffering from syphilitic roseola, and two well-marked indurations in the furrow at the base of the glans penis. The patient states that between the 1st and 15th October, 1869, he had connection several times with the same woman, and only with her. Before that period, for at least one month, he had had venereal intercourse with no one, and since the 15th October until I saw him he had not had connection at all.

Until the 1st December—rather more than six weeks after the last connection—he did not observe anything wrong. He stated, however, that he felt cold rife, and that he did not consider himself to be in such good health as usual. At this date he first noticed what he termed "two little broken places," one on each side of the base of the glans penis (fissures, in fact). These gradually increased in size, and on applying to a quack doctor—a week after their first appearance—induration was remarked around each ulcer. This induration gradually increased, and the two masses fused together across the dorsum of the glans. The patient states they were as large as small beans.

On January 11th, or six weeks after the first appearance of the sores, he noticed a series of red spots over the whole of the body. After four days these began to fade, leaving stains behind. He had also severe lumbago and sore throat. The cervical and inguinal glands were hard and enlarged, and he had rheumatic and osteocopic pains. The sores furnished little or no discharge, gave the patient no pain, and healed in a month after their first appearance. By the 1st of January they had soundly healed. On the present day—February 28th—the characteristic induration, although diminished in size, persists in a very distinct manner. The treatment employed was the use of the Turkish bath, and five grains of iodide of potassium thrice daily. No further manifestations of syphilis have shown themselves. I endeavoured to trace the source of this man's infection, and succeeded in discovering her. She had only come to Belfast within a limited period. I discovered that she had been a patient in the union workhouse, and Mr. Johnston, the surgeon to the infirmary, remembers the woman, and that he put her on mercurial treatment. She gave birth to a dead child prematurely while in the hospital, and left as soon as she was convalescent. It is clear, then, she was suffering under syphilis before going to the workhouse. I sent my patient after her to persuade her to submit to an examination to ascertain her present state, but without success. In hospital at present there is a patient under the care of my colleague, Dr. Murney, who says he was infected by the same woman, and I am told of two others in the same plight. I think this surely is a case for the application of a Contagious Diseases Act.

Case II. is that of a young medical man, a friend of my own. He was especially healthy, and, at the time of the suspicious connection, twenty years of age.

On June 18th, 1868, he had intercourse with a woman, whom he afterwards discovered had been under treatment in a Dublin hospital, with secondary syphilitic eruption, a short time previous to his meeting her. For a year before this he had been preparing for his examinations, and had not indulged in any illicit intercourse for several months antecedent to June 18th, a date he is able to fix precisely as being the day on which he passed. Subsequent to this he went with his friends to the sea-side, where he shot and fished, and otherwise amused himself, but had no venereal intercourse since that which he had with this woman on the 18th. He experienced nothing whatever for four weeks. When bathing on the morning of July 15th he noticed that the inner surface of the prepuce was excoriated, and on each side he afterwards noticed a small fissure, which subsequently developed into a large superficial sore. He imagined that the excoriation was produced by the sea-water, and applied strong astringents, which only further irritated the part. These sores appeared in the third week in July, or, as nearly as possible, twenty-eight days after the connection. A week after their first appearance the sores began to indurate (he was accustomed to bathe every morning and is sure he noticed the first indication), and the glands in

the groin and neck became indurated also. There was very little pain or irritation in the ulcers. On the 16th August, or four weeks after the appearance of the sores, a well-marked eruption of syphilitic roseola appeared, which lasted only two days, and at this date the sores had healed. Other syphilitic symptoms subsequently made their appearance, but all of a very mild type. He consulted me from time to time and I counselled mild measures; but he took the treatment very much into his own hands. I recommended to him the bichloride of mercury in doses of 1-16 grain for a limited time. He, however, soon changed to the protiodide of mercury, which he took in three-grain doses, and altogether continued to mercurialise himself without salivation for a period of seven months, one month longer than Ricord's classical period. He could not, however, take iodide of potassium, as it produced intense coryzæ, or he might have dosed himself with it three or four months.

Now, in these two cases, the date of infection, and the date of what Lancereaux calls the period of local eruption, are pretty clearly defined. In the first case for forty-two days after the last intercourse there was nothing to indicate that syphilitic inoculation had taken place; in the second case the period was somewhat shorter, being twenty-eight days. In both cases the source of contagion was presumably a secondary syphilitic lesion. This source of contamination was until lately most persistently denied, but it has been established upon an experimental basis beyond question of doubt. It would appear, from the inoculations that have been practised upon healthy persons, that the period of incubation is longer in accordance as the source of infection is further removed from the initial stage of chancre. In Rollet's case, where the matter of an infecting chancre was inoculated on a patient having two soft sores, the latent period reached eighteen days only. When the source of contamination was taken from a secondary healthy lesion, the period of incubation was extended to thirty-five days, or even much longer. According to Sigmund, however, this incubation period does not exceed the fifth week in the great majority of cases, and very frequently it does not pass the fourth, which may be taken as the average.

Diday asserts—and these two cases would tend to strengthen his view—that syphilis communicated from a secondary lesion is milder than that arising from a chancre, and it would then follow that the longer the period of the incubation the milder the subsequent attack of syphilis would be.

Dr. M'Donnell in the Medical Press, Feb. 9, records five most interesting and crucial cases, from which sources of error have been carefully eliminated, and in these the period of latency is about the average recorded by other observers – namely, 28 days; the periods in each case are, 27, 28, 33, 41, and 34 days, respectively. Dr. M'Donnell justly remarks how seldom cases occur which will bear the test of scientific accuracy. I believe these two cases are worthy of being placed along-side of his, and that they will help to establish on a clinical basis what has almost been proved experimentally—the incubation period of syphilis.

The conclusions to be drawn from the observations of this period of latency are very important from a practical point of view. They show that true chancre is not the point of origin of syphilis, but merely the initial symptom of the constitutional infection, and that all attempts to eradicate the disease by excision of the chancre, or its cauterisation, at however early a period these may be performed, are simply useless, or worse than useless. True syphilis would thus seem to possess its period of incubation, and its period of invasion, antecedent to the outbreak of the general manifestations of the disease, but of a more chronic type, just as other so-called zymotic diseases. In fact, the indurated or infecting chancre, as it has been called, should, I think, more properly, perhaps, be called the first of the secondary symptoms. It would not be within the scope of these few remarks to point out what I believe to be the well-marked and distinguishing characteristics of infecting and non-infecting chancres. The initial symptom of syphilis, I believe, varies, and is by no means constantly to be met with under the form of a Hunterian indurated chancre; but soft or non-infecting chancre vareis in its distinguishing characteristics very little in different instances, and may, in most cases, be readily recognised. I am by no means disposed to deny that there are cases of difficulty which cannot be ranged under either category, but for the great majority of cases the duality of venereal sores is a doctrine to which I lend my full adhesion.

In all cases of doubt it is better to wait a little for the development of the disease. The soft or non-infecting chancres usually present characteristic and constant appearances. The initial symptom of syphilis is variable just as the later manifestations may vary, but not in the same degree.

In the case of true syphilis some delay cannot prove injurious. The administration of mercury may modify, but it cannot prevent, the manifestations of syphilis. Besides, another great desideratum accrues from a little delay—the activity of the treatment can be guaged by the violence of the disease. Ricord's treatment of six months iodide of mercury and then three months iodide of potassium, is quite unnecessary, and therefore injurious in such cases as the two I have recorded. Where syphilis assumes so mild a type very little treatment other than hygienic measures is required, and of these one of the best is the Turkish bath, and to this a short course of iodide of potassium may be added.

In both these cases the induration supervened upon the sore. There was not an induration first and then an ulcer.

Since writing the foregoing remarks I had an opportunity of examining the *origo mali* in the shape of the woman who infected the policeman. She had been re-admitted to the union hospital, where I saw her on Friday, March 5th, covered with condylomata, both anal and vulvar—some secreting, some healed. I ascertained from her that the dates assigned by the policeman for his intercourse with her had been correctly given, and that she had been under treatment in the hospital for manifestations of secondary syphilis at the end of October and beginning of November. My surmises were then correct as to the secondary origin of the contagion, in the first as well as the second instance I have quoted.

WERE THE PRIESTS OF ANCIENT EGYPT THE FIRST PHYSICIANS?

By M. Donovan, M.R.I.A.

Some wags, more witty than wise, have said that physicians are the offspring of sin; for, say they, one of the immediate consequences of the disobedience of the two first inhabitants of the world was the denunciation of disease and death on their posterity. But they forget that curative herbs were created before man sinned, from which we may infer that life was not intended to flow in an uninterrupted stream of health. Thus physic can be traced, not to the fall of man, but to his state of innocence, and thus punishment was tempered with mercy.

It is reasonable to suppose that the means of alleviating corporeal suffering was one of the earliest of human pursuits. Many an absurd story has been related about the origin and first notions of remedies. Galen does not think it beneath him to report that the medical art was said to have originated in the recovery of sight by a goat, which was accidentally wounded in the affected eye by a pointed bulrush. He also quotes an absurd story related by Ælian to the effect that enemata are imitations from the bird Ibis, of Egypt, which, filling the skin of her long neck, as if it were a bladder, with the water of the Nile, introduces it into her body by means of her bill.

The relief of the sick by artificial means must have

originated in casual observation, for nothing can be less obvious to the primitive mind than the possibility of alleviating a morbid condition of the body by the introduction of substances which are not articles of food. That relief from pain is procurable from external application is a fact much more easily discoverable, for here both reasoning and accident might contribute to disclose the important truth. A person scorched by fire would naturally try the remedial efficacy of cold, and the relief which he would obtain from it might induce him to try the effects of external refrigerants in local inflammations arising from other causes, and hence would originate the idea of topical applications. But no hint of the use and powers of internal medicines could be derived from such sources, or from reasoning, however easily it might from accidental causes of very probable occurrence. The results arising from the eating of agreeable sour or bitter herbs, or trials of the fitness of different plants and roots as articles of food, might disclose influences over the animal economy, that would soon arrest attention, and suggest a search for other medicinal agents, possessing the invaluable property of controlling the aberrations of health. In such a view, there is, after all, little of conjecture, for the probability is so high as to produce conviction that in some such way must the art of restoring health have originated.

It would soon happen that persons whose inclination led them to inquire into the properties of simples would progressively collect information which people generally did not possess, and at length would be so far distinguished for this useful attainment, that their opinions would be sought and deferred to, however crude their conceptions and simple their means. In such beginnings the art of medicine very probably originated, and, if so, it is in vain to search for its invention in any particular country. It was invented everywhere, if the expression be allowed, as soon as a community existed, and, accordingly, the ancient authorities place a discoverer in almost every country of the Eastern hemisphere. It was of course cultivated in some places more than others. Conringius says—"*Apud Ægyptios tamen pene primo omnium illam magis solitæ cultam, extra dubium videtur esse.*"—(*Univ. Art. Med.*, 1687).

Ancient Egypt has been always considered as the earliest nursery of science and literature. The priests were the appointed guardians of knowledge as well as the superintendents of the education of youth; and, from the little that can be collected on the subject, it appears that the priests did not possess much of the learning at that period, and pretended to more than they knew. Amongst the records kept by the priests, history alludes to some which related to a kind of medical code, much mystified and disfigured by superstition. There is a passage in Isocrates on which the learned Dr. James founds his opinion that the priests of ancient Egypt were the first practitioners in medicine. The passage quoted by Dr. James is as follows:—"The priests, who enjoy many advantages, have for the relief of the afflicted invented a system of physic which does not prescribe dangerous medicines, but such as may be used as safely as their daily food; hence it is that the Egyptians are a people of sound and robust constitution, and live to a great age."

This does not, however, in my mind substantiate the fact which it is brought forward to support, viz., that the priests of Egypt were the first practitioners of medicine. It seems to prove two positions of a contrary tendency; first, that the priests invented a *mild* practice of physic, and, secondly, that there was some *other* practice, in which powerful and dangerous medicines were used. Why would the invention of a gentle mode of treatment be spoken of in terms of commendation, unless there had been in use a more rough and dangerous method, which was not of their invention, and with which a comparison was made? From this quotation the inference might also be drawn that the practice of the priests was a simple preliminary treatment, employed only in mild forms of disease; while the exhibition of more active remedies was reserved for a different class of practitioners. To administer relief of the former kind would be but an act of humanity, and such as would be expected from their sacred calling, especially as it appears they were liberally provided for by the State.

Diodorus Siculus says that "Out of the records in the sacred registers from things done in former times, they (the priests) read profitable lectures for present use and practice" (lib. i.). To understand this, it is to be remembered that the inscribing of knowledge on columns was a device anciently practised in certain parts of the world. Josephus says the sons of Seth inscribed two columns, one of brick and the other of stone, with their astronomical discoveries. It appears from various testimonies, that in the age of Hermes, and long after, it was the custom in Egypt to inscribe their literature on columns, instead of writing it on the papyrus (Conringius). Hermes, otherwise Mercury, otherwise Thoth, inscribed all his knowledge on columns. These writings were in the care of the priests; they were no doubt the same that they employed as a source of information for their lectures, for we have it on the authority of Eusebius, that they were preserved in the most secret places of the Egyptian temples, and, according to Clemens of Alexandria, some of them were on medicine.

Thus the passage of Diodorus, above quoted, shows that in his time the duty of the priests was to instruct the people in the knowledge contained in the sacred registers, some of which were on the subject of medicine, to the use of which the people were very much addicted. The medical knowledge which their profession thus obliged them to possess, was that which they employed in charitable dispensations. Its quality may be judged from the circumstance of its immutability and antiquity. But if this is to be received as evidence at all of the interference of the priests in medicine, the following has an equal claim. In another place Diodorus says—"The physicians make use of receipts prescribed by law, constructed by the ancient physicians; if they cannot cure the patient with them, they are never blamed, but if they use other medicines, they suffer death, inasmuch as the law-maker appointed such receipts for cure as were approved by the most learned doctors, such as by long experience had been found effectual." Here, then, both ancient and modern physicians are expressly mentioned, but not a word is said of their being priests, nor in any other part of the histories of Diodorus, and there can be little doubt that, had the two characters ever been combined, he would not have failed to mention a circumstance so unusual in the customs of mankind as the execution of their priests, protected as they have always been, even in the most barbarous ages. Strabo details the duties of the priests (lib. xvii.), and speaks of themselves elsewhere, but does not allude to their exercising the art of medicine. Herodotus speaks distinctly of physicians, and the regulation of their profession: He says—"The Egyptians, in the pursuit of health, take a variety of strong medicines during three successive days in every month, believing that all diseases arise from repletion. Next the Libyans, they are the most healthy; they eat certain fish and birds raw. The medical art is thus distributed by the Egyptians:—Every disease has a physician to itself, who cures nothing else; all places are filled, therefore, with medical practitioners. There are doctors of the eyes, and doctors of the head, and doctors of the teeth, and of the stomach, and of all inward complaints" (Taylor's "Herodotus" ii., 136). But not a word is said of the supposed twofold ministry of the priests.

Let us now contrast this body of negative evidence with a passage in Clemens of Alexandria, on which Dr. James partly founds his opinion. He says—"There were forty-two books of Hermes of great account, which contain all the philosophy of the Egyptians; the six last are in a more particular manner studied by the παστοφοροι, pall or cloak-bearers (a particular order of priests), as relating to medicine. These treat of the constitution of the body, diseases, instruments,

the eyes, and lastly the disorders peculiar to women." Dr. James translates παστοφοροι pall or cloak-bearers "a particular order of *priests*." Why they should be designated priests does not appear: the etymology παστον φερω does not convey that signification: "παστοφορος ædituus" a church-warden (*Hederici Lex*): "one who carries about a case containing the image of a god" (Donnigan): παστον a chamber or house of a priest, and φερω to carry (Donnigan): these are the only traces of the priesthood I can find in the word, but they do not indicate that the παστοφοροι were priests, much less that they were physicians. The passage in Clemens merely declares that the subjects mentioned constituted in a more especial manner a part of the education of the παστοφοροι, whatever their office may have been; but no sufficient reason appears to induce a belief that they were priests; and still less that they professionally practised the medical art as supposed by Dr. James.

On the whole, it does not distinctly appear, by any historical record, that medicine was practised by the priests of ancient Egypt; and several historians who treat of the state of physic in these ages, by their silence on the subject of its being the province of the priest, disprove the existence of such a custom. We only find that these sacred characters made the healing art a part of their studies; they were obliged to do so, because we learn from Celsus and others, that medicine, in its early ages, was a branch of philosophy; and from Pliny that it remained so down to the days of Hippocrates who first separated it. Now, the Egyptian priests being the conservators and diffusers of philosophy, and well paid for their labours by being in possession of one-third of the land, were bound to understand and teach physic as a part of a general education. It should be recollected that Clemens flourished in the second century of the Christian era; that Diodorus and Strabo were his predecessors by half a century; and that Herodotus lived no less than six centuries and a-half before him. Whatever advantages the first had with regard to knowledge of ancient usages, so had the others in a greater degree. If Clemens alluded to his own times, his evidence does not apply; and he seems to do so. If it be affirmed that the usage is of much more ancient date, then the statement is unsupported by historical evidence, and is even opposed by the silence of historians professing to write on the very subject.

It is probable that in ancient Egypt medicine was thus regulated: the physicians procured transcripts from the priests of the prescriptions authorised by law, and employed them as they were bound to do under penalty, the priests occasionally using the same formulæ in cases perhaps of charitable dispensation. No doubt this kind of legal medicine was common amongst the people; for they were all addicted to inordinate care of health, and to remedies; so much so that some ancient authors have sarcastically said that the Egyptians were all physicians.

The professed physicians were only bound to treat diseases according to law for the first four days; previously to the expiration of that period, the administration of a purgative would be punished with death: but after it, they might use their own judgment. This extraordinary fact is testified by Diodorus and Aristotle, the latter of whom thus epitomises it:—"It is stupid in any art to govern according to written rules. So in Egypt, it is lawful for physicians to adopt a different mode of cure after the fourth day; but if they adopted it prior to this, it was at their own peril" (Taylor's "Aristotle" p. 342). The treatment of the incipient disease we know often determines the sequel: the physician had to contend with legal disabilities, and little character could be derived from practice constrained by law: but they were rendered independent of character; for Diodorus says that they were allowed a salary from the public income. It seems pretty certain, therefore, that medicine never made much advance in a country where improvements were in a manner interdicted by law, and punished with death.

It may be here observed that the learned Conringius does not even suggest the idea of the union of medicine with the office of the Egyptian priests, notwithstanding his extensive researches on all subjects connected with medical literature, although he thinks the art was first extensively cultivated in Egypt. It is quite a different thing, however, to admit with Pliny the value of the oracular dispensation of cures vouchsafed by the gods which we know were delivered by the priests, and which, by acting on the imagination, often effected surprising recoveries, as indeed the supposed intervention of supernatural agency has done in our own days.

Throughout those parts of the Old Testament in which Egypt is mentioned, there occurs nothing that could lead to the belief that the medical care of the sick was entrusted to the priests. But there is a passage which may be understood in such a way as to render it probable that seventeen centuries before the birth of Christ there were persons practising medicine as an independent art; and who are consequently the first physicians that appear on the records of history. The subject is curious, and it may be interesting to inquire what sort of persons these practitioners were. In the 50th chapter of Genesis, verse 2, we read, "And Joseph commanded his servants the physicians to embalm his father, and the physicians embalmed Israel." The Hebrew root of the word "physicians" means to heal (Parkhurst), and, as a plural masculine noun would mean *healers*, hence some sort of medical practitioner would be meant. It is true the word also means giants, but that cannot be its acceptation here. But it appears that these persons also embalmed Jacob, a duty which required much experience, and which was, of course, a part of their profession. Now we know that many medicinal substances were used in the process of embalming; and these it was the duty of the physicians to understand how to mix, and to employ. But if their profession were to heal diseases and to preserve bodies, and if the latter duty required that they should mix and employ medicines, it is to be supposed that they would render the same services in the healing department; for why should they provide and use medicines for one branch of their profession, and not use them for the other, which was by far the more useful? If this view be correct, Joseph's physicians were practitioners who, besides prescribing for diseases, provided medicines and fitted them for exhibition—a very natural association of duties; and, when occasion required, opened, disembowelled and preserved dead bodies. They were, therefore, in some respects, the same as the general practitioners of the present day, and this would be evidence not only that the real practice of medicine, of whatever kind it may have been, was not in the hands of the priests, but that general practitioners have existed as a profession for 3,500 years.

It has been sometimes admitted that, amongst the Jews of antiquity, medicine was practised by the priests, because in some parts of the Scriptures they were enjoined to perform certain services for the sick. They had it in express command from God to watch over "the plague of leprosy;" and, from the same Divine source, they were taught the symptoms by which that loathsome disease was to be distinguished. In the 13th chapter of Leviticus, we find ample details on this subject: and this fact is in conformity with the opinion that the priests had never made disease their study, since it was found necessary so minutely to describe the symptoms of leprosy, in those days so common a calamity.

In taking leave of this part of the subject, one observation only need be made. It is certainly true that in ages near our own times, the clergy and persons under religious vows, did, in various countries, minister to the corporeal as well as the spiritual wants of the people. Fosbrooke, in his work on "British Monachism," gives facts of this kind, but very much disparages the motives. Speaking of England, he says—"Medicine was mostly professed by clerks, because they alone were capable of reading the Latin works on the art of healing. From the nature of some of their prescriptions, there appears an evident intention of confining this art, as well as others, to the dogmas

of the existing religion ; for which reason relics were introduced into the materia medica. The hairs of a saint's beard, dipped in holy water, were taken inwardly (he quotes M. Paris). A ring taken from the body of St. Remigius, and dipped in water, is said to have produced a drink very good in fevers, and different diseases. Relics were also hawked about, and money given to the bearers for access of the sick to them."

A little intermixture of worldly policy may be found also in the clerical medicine of other countries. Amongst the negroes of the Gold Coast, the priests have been always the physicians. When the priest was consulted, he first took care that a proper offering was made, as a sheep or a hog, according to the circumstances of the patient ; without which a recovery could not be effected. A new offering must be made if the disease increased : and if it proved obstinate, many other of the sable physicians would be called in, each of whom would piously suggest that the offering should be renewed.

In China, to this day, the priests as well as the physicians practise medicine, such as the practice is. In some parts of Hindoostan, the priests not only had the care of the sick, but fed and clothed them. Sir John Chardin, in his travels in Mingrelia, informs us that the duties of physician and surgeon to all Mingrelia were discharged by a Theatine friar. But we have better instances of clerical medicine than any of these, A learned dispensatory was written by a priest of Tournay named Joannes de Sancto Amando. Basil Valentine, the author of "Currus Triumphalis Antimonia," which made us acquainted with the virtues of antimonials in many diseases, was a Benedictine monk, and as he himself says, a scarcely ever failing physician. Kermes mineral, which once enjoyed a high reputation as a medicine, was brought into notice chiefly by a Carthusian friar, and hence was called Carthusian powder ; it was made generally known by an order of the King of France in 1720. Peruvian bark was originally called Jesuits' powder, because first introduced by that order of the priesthood. Many other instances might be adduced ; but enough has been said to show that although the sacred profession did not give origin to the art of medicine, it contributed to its improvement, and often applied it to the alleviation of human suffering.

Amongst some of the nations of antiquity there was neither an acknowledged code of medicine, nor physicians; nor did the priests interfere in medical affairs. Whatever knowledge of remedies existed was diffused amongst the population ; and this, when necessity required, was called into action in a singular manner. We can easily conceive how crude, incongruous, and absurd must have been the chaotic mass of notions which could be suddenly collected from street passengers, and which was nevertheless to guide, or rather bewilder, those who had the charge of the sick. Such a state of things existed in the days of Herodotus, four centuries and a half before Christ, in the splendid City of Babylon, which, although it boasted one hundred brazen gates, could not, on an emergency, produce one physician. That traveller and historian says—"The Babylonians have an excellent practice ; they have no physicians by profession ; but those who are diseased, being brought into the public places, whoever passes the sick man advises with him concerning his disorder ; and if he has himself at any time laboured under the same complaint, or knows one affected in the same way, recommends the remedies by which he himself, or others, were cured. To pass a sick person in silence, without inquiring his complaint, is deemed a breach of duty." (Taylor's "Herodotus"). Strange that so dangerous a practice should have been considered excellent.

The same usage obtained at Rome. It is affirmed by Pliny that for six centuries after the foundation of the City, there were no physicians in that capital. During that period, the custom was to carry the sick to the Forum, in order that the opinion of passengers might be taken on their cases. It is probable that Pliny meant Roman physicians when he specified six centuries ; for in another place he states that the Physician Archagathus settled at Rome, U.C. 535. And Dionysius, of Halicarnassus, says that in the year 301 after the foundation of the City, so dreadful a pestilence raged in Rome that there were not physicians enough there to attend the sick. It must be admitted, however, that there were no Roman physicians ; for all who practised in Rome were Greeks. The Romans made no progress in medicine, and little in any of the sciences.

The Greeks imitated the Egyptians in everything; so much so that a resemblance is observable between many of the institutions, customs, and opinions of the contemporaneous people of the two countries. The Greeks piously stole occasionally an Egyptian deity, and one by one borrowed the whole Egyptian mythology, and converted it to their own purposes, sometimes palpably, and sometimes under names which effectually screened the theft. In like manner, they borrowed their medicines and medical opinions, and adopted something like their mode of collecting medical knowledge, and performing cures. The Egyptians had their Thoth or Hermes ; everything that related to him was accounted sacred ; he himself was worshipped as a divinity ; and on him was bestowed the superlative epithet, "Trismegistus," or *thrice renowned*. From this deity their notions of medicine were derived. The Greeks attributed a descent just as lofty to their art of medicine. To their Esculapius they gave the glory of its invention, and in gratitude for his favours they deified him. No less than sixty-three temples were dedicated to him in Greece and her colonies. His wonderful cures were recorded, not on pillars, but on tables of marble ; and long after his death he considerately communicated with his votaries concerning their health. It was the custom to bring all sick persons to the temple of Esculapius, where the priests and priestesses, who were the descendants of the god, propitiated his favour for the patient. Various ceremonies and mystical solemnities were practised on the sick, the influence of which acting on their disordered imagination seldom failed to produce visions or dreams in which the promised disclosure of the mode of cure was made, or fancied to be made, and which disclosures the priests assured them were vouchsafed through the direct intervention of the deity Esculapius himself. The patients, when recovered, left behind them a record of their cure, and all discoveries thus ascertained were engraved on tables of marble, and deposited in the temple. Such implicit reliance was reposed in the records of this temple, that Galen declares his patients would more willingly have abided by them, or by their dreams, than by his prescriptions. Fortunately, however, for the purses of the regular practitioners of antiquity, the temple with all its records and nostrums was consumed by fire ; and thus an end was put to the very profitable trade which was therein privately carried on by the priests.

This Esculapius, a Phœnician by birth, deserves some notice as one of the fathers of the healing art ; for, notwithstanding the ridiculous accounts of his life and parentage fabricated by the Greeks, there can be little doubt that a person of this name did once exist, although of much more humble origin and less extravagant pretensions. It is matter of history that he was surgeon to the expedition of the Argonauts ; and that he was instructed in the knowledge of simples by an eminently accomplished person whose name was Chiron, and whose life has been so mixed up with fables, that we know nothing of him more than that the constellation Sagittarius commemorates his skill.

Esculapius seems to have flourished about 1263 years before Christ. The following account of him given by Diodorus Siculus (Lib. iv., cap. 4.) probably contains some obscure truths amidst the disguise of fiction and absurdity in which it is dressed. Esculapius, the son of Apollo and Coronis, was a person of acute intellect. Earnestly devoted to the study of medicine, he discovered many valuable remedies, and at length performed such wonderful cures of persons whose cases appeared hopeless, that he was re-

ported to have raised numbers from the dead. Pluto, on learning this, complained to Jupiter that, in consequence of the recoveries effected by Esculapius, the periodical number of deaths decreased, and that the empire of his infernal majesty was seriously threatened. Jupiter was so incensed that he hurled a thunderbolt at Esculapius, and put him out of condition to recover any more dead men.

THERAPEUTICAL MEMORANDA.

STRYCHNIA IN FATTY DEGENERATION OF THE HEART.

By J. Waring-Curran, L.K. & Q.C.P.I., L.R.C.S.I., &c.

During the summer months cases of heart disease appear more frequently and impart the impression that affections of this important organ, by their greater prevalence and the urgency of their symptoms at particular times, are influenced or controlled by the state of the atmosphere in a great measure. In the district in which I reside patients who laboured under fatty degeneration seemed to suffer in a very marked degree during the months of July and August of last year. The majority of those patients whose malady I successfully battled against by a treatment to be presently explained, passed through the winter remarkably well, and did not evince any return of the distressing symptoms so characteristic of this form of heart disease until the end of June, Wednesday the twenty-second being one of the hottest days since the hot period of last July. In treating cases of fatty heart accompanied by all the pathognomic symptoms of the disease, I have hitherto experienced much uncertainty, and, in many instances, vexatious disappointment. My attention was first accidentally directed to the great value of strychnia as a therapeutic agent in this malady by my prescribing it for a lady who suffered from a non-inflammatory affection of the spinal cord, and who, at the same time, possessed a fatty heart. Under the action of a mixture whose chief components were liquor strychnia and iodide of ammonium—a drug I have elsewhere shown to be more powerful in its effect, and more strikingly efficacious than the iodide of potassium—I was struck with the effect produced upon the heart, and the rapid manner in which the organ appeared to recover itself after a couple of weeks' treatment. I was strongly tempted to push my experiments further, and during the hot months of last summer I had ample opportunity of so doing, and of thoroughly satisfying myself that the strychnia produced a more marked and more beneficial effect than any other drug hitherto prescribed by me. Under its influence I noticed patients rally and obtain quiet sleep, who dreaded lying on the back, and I observed severe forms of dyspnœa pass off, and sharp attacks of angina subside from its use. The preparation I invariably used, and continue to employ, was the liquor strychnia. I commenced with four grain doses equivalent to the one-thirtieth of a grain, steadily increasing it until I gave what was equal to one-tenth of a grain, together with two grain doses of the iodide of ammonium, a small quantity of spirits of chloroform and camphor julep as a vehicle. In some cases I was forced to forego the administration of the drug (owing to the supervention of muscular twitchings, but, very curious to mark, the twitchings commenced about the precardial region, and in one instance confined themselves to the left arm), and substitute the citrate of iron and ammonia for a few days instead. I also recommend the iodide of ammonium to be freely rubbed in over the heart in the form of cerate. Should there be fainting attacks I advise small quantities of brandy or sal volatile, but I have ever remarked, once the powerfully stimulating effects upon the muscular system of the strychnine manifests itself, that syncope and cardiac distress pass off. Some authors tell us that strychnine produces paralysis of the heart: an over dose of the drug may have such an effect; but my experience is, that, by its operation on the whole system through the medium of the spinal motor nerves, it produces a powerful tonic effect in certain debilitated conditions of the system, and that in no disease is this more readily appreciable than in fatty degeneration of the heart, wherein it acts very powerfully in giving tone to, and increasing in a marked manner, the muscular contractions of this organ. My object in combining with the strychnia the iodide of ammonium was that it might act as an alterative and absorbent.

Literature.

LECTURES ON CLINICAL MEDICINE.*

We hail the appearance of this volume with pleasure. Like its predecessors, it is full of valuable matter; and by a physician who, we believe, had no superior, if indeed he had an equal. Since we last spoke of him, this great physician has passed away, leaving the Profession, however, many mementoes of his unrivalled powers of observation and reasonings. As he thought highly of our Graves, whose works he so constantly quotes, so may we think of him, and undoubtedly there were many points of resemblance between the two men. But this is not the place to enter on such a subject. The present volume has been issued by the Sydenham Society, as one of its yearly volumes, and they have done good service in so acting, not only in this, but in the former volumes.

The present one is made up of twenty-five lectures, or as we think they should be called "Clinical Essays," for this would represent what each, in reality, is. To enter into these separately would far exceed our present limits. We can only then refer to those which strike us as being peculiarly good. The third in the volume is on "Ozæna" and the reader will find it full of important matter, as well as the treatment the author has found the most effectual in this complaint. Of its great obstinacy we are warned again and again, and indeed for ourselves we consider the disease, especially in its severe forms, almost incurable. It is very easy to relieve it, and apparently cure it. But it is sure to return, and must too often be looked upon as a life-long disease, as well as one which entails frequently great misery, as regards the fœtor, and quite capable likewise of slowly but surely sapping the springs of life. So much depends on the local treatment that we may venture to hope that the improved methods of examination of the back of the throat and nose, lately introduced, may help powerfully in aiding the cure of the disease, for we have little doubt, if all the parts affected could be reached, the disease would be much more amenable then it is. Our space prevents us noticing several valuable lectures on Affections of the Larynx; Phthisis; Hæmoptysis, &c. But we would direct the special attention of our readers to the several chapters which follow on Pleurisy, and its Results; particularly the question of tapping the chest. Nowhere will there be found such a full and, in every way, complete account of this subject as in these pages. It was well known the author was a strenuous advocate for early operation in these cases, and the success resulting certainly seems to prove he was right. In these countries it is not the practice to interfere at such an early stage, and the question arises—do we not then lose valuable time by such delay? It is only right to state that a London physician—we think it was the late Dr. Addison—strongly advocated early operation, and this several years since. There is, however, a point not to be overlooked in this matter, and this is, that the British practice is, we believe, more effective than French. Hence it follows that in many

* Lectures on Clinical Medicine, Delivered at the Hotel Dieu, Paris. By A. Trousseau. Vol. III. Translated from the Edition of 1868. Being the revised and enlarged Edition. By John Rose Cormack, M.D. Edin., F.R.S.E., Fellow of the College of Physicians of Edinburgh, &c. London: The New Sydenham Society. 1870. Pp. 557.

cases, at least of pleuritic effusions, the disease yields to the treatment, and surgical interference does not become necessary. In discussing this subject, it may be well not to overlook the point. It should be stated that the lectures on this important subjects, are illustrated by a number of very well detailed cases, and also that the subject of traumatic effusion of blood into the pleura is also considered, but into it we cannot enter. We have here to pass by some of the valuable lectures ; but one devoted especially to the treatment of pneumonia calls for some remarks. We need not say what a difference of opinion exists at the present day on this point, some holding that our treatment should be entirely expectant ; and others doing so little that it may be considered but a modification of the former. We do not side with either of these ; we much prefer acting according to the emergencies of each case. It is not, however, of our own views we would speak here, but of the author's, and we are very glad to find him advising antiphlogistic treatment, including drugs and antimonials. He makes also the important remark, that the same doses of antimonials will not be borne at one time as at another, thus confirming the experience of all the great minds who have gone before him, and refuting the ideas of those who hold that diseases are ever the same, and who make the treatment of disease a routine. The reasoning and observations which run through the entire lecture seem to us unanswerable, and we only wish we could enter more fully into them. The concluding part of this essay is, we ought to add, occupied with the subject of pneumonia, as it attacks the upper lobe of the lung, and also the treatment of some of the forms of delirium which attend frequently on the disease by means of musk.

The lectures which follow we can only name. They are on "Tapping the Pericardium, and Organic Affections of the Heart," "Alcoholism," "Spermatorrhœa," "Nocturnal Incontinence of Urine," "Glucosuria," "Polydipsia," and "Vertigo." We can only say for these that each and all of them are full of interesting and practical matter, and any of our readers who may want to consult the book on any of these subjects will not be disappointed here. Indeed, where all the volumes are excellent we are not sure but that the present one is the best, and we only wish there may be more to follow.

SCOTLAND.

Not very long since we took occasion to make a few remarks upon the necessity of some reconstruction of the curatorial board in the University of Edinburgh, similar to what was proposed by Sir Alexander Grant, in his address at the opening of last winter session. It was no actual transgression into which the curators had fallen in their appointments to medical chairs, which led us at that time to advocate this reform; on the contrary, we had particular pleasure in referring to the admirable manner in which they had exercised their patronage. But the histories of the appointments were not such as to encourage the belief that future vacancies would always be filled with equal judiciousness. The constitutional weakness of the board was too well known to us ; and, while with grateful astonishment we reviewed the past, it was with trembling anxiety we anticipated the future.

We now feel how utterly disproportionate our worst fears have been when viewed in connection with the actual realities which the recent election to the Chair of Midwifery has established. The magistrates of Edinburgh, in their capacity as delegates to the court of curators, have with characteristic impetuosity and unreasoning zeal been endeavouring to anticipate the national memorial to Sir James Simpson ; and, by placing the gown which had fallen from his shoulders upon those of his kinsman, have imagined they were conscientiously discharging a solemn duty, in gratifying their own eccentric notions of what is due to the name of Simpson. This is, perhaps, he most charitable view to take of their recent act ; and in this aspect it would be sufficiently ludicrous, were it not for the disastrous consequences with which their clumsy enthusiasm is fraught.

We are spared the painful necessity of pointing out the immediate injury done to the University in the person of the recently elected professor. With singular unanimity of opinion the Profession and the public have openly agreed in considering him as occupying the position of an obstructive. If with this decision *he* is satisfied, we have no other course but to submit. But what are the prospects of the University of Edinburgh if the present constitution of the curatorial board is continued ? When a vacancy again occurs, with what reason can we believe, what reason have we to hope, what right to expect, that men of eminence will present themselves as candidates for the appointment, or expose themselves to the risk and mortification of having their just claims ignored, because they are not sufficiently popular to satisfy the unsearchable understandings of the municipal delegates ? We greatly fear that the higher the qualifications of the individual the greater will be the unwillingness to undergo such an ordeal.

It is commonly affirmed that out of evil a certain amount of good may be confidently expected to result. We are inclined to hope that this may be the case in the present instance. While the election of Dr. A. R. Simpson supplies an answer to the familiar question of "What's in a name ?" the rejection of Dr. Duncan affords conclusive evidence of the utter uselessness of the present system of testimonial-giving. The principle has been defended on the ground that testimonials assist in guiding the decisions of a mixed constituency, and they are said to be specially adapted to the intellectual capacity of those who occupy seats in our municipal councils. The folly of such reasoning, and the falseness of the premises upon which it is based, are abundantly proved by the result of the recent election. Dr. A. R. Simpson was elected by the delegates of the town council on account of the name he bore, which, for the sake of appearances, was supported by a batch of testimonials which had failed to get for him a similar chair in the University of Glasgow ; and Dr. Duncan would have been elected by the delegates from the University on account of work accomplished and success achieved, and which, irrespective of the combined evidence of the one hundred and thirty-four splendid testimonials he presented, entitled him to all he desired at their hands.

Of the successful candidate we have no wish to speak with disrespect. We have always understood him to be an excellent man, and a most successful practitioner. The most that can be said of him is, that he is the nephew of Sir James Simpson, and his successor in his chair. We trust time will be good to him, and that in his present difficulties he will meet with friends who are wiser and better able to advise him than those who placed him in them.

Professor Lister has been appointed Surgeon in Ordinary to the Queen in Scotland.

University of Edinburgh. — Election of Professor of Midwifery.—The curators of the University of Edinburgh met on Monday, the 4th of July, in the University Court-room, for the purpose of electing a Professor of Midwifery to fill the chair rendered vacant by the death of Sir James Y. Simpson. All the curators were present, with the exception of Bailie Skinner, who is at present on the Continent, but who had left a sealed paper containing his vote. Dr. Alexander R. Simpson, Glasgow, was nominated by the Lord Provost ; Dr. Keiller by Bailie Russell ; and Dr. Matthews Duncan by Sir William Gibson-Craig. Bailie Fyfe spoke in support of Dr. Simpson, and Lord Neaves and Mr. D. Milne-Home in support of Dr. Matthews Duncan. Bailie Skinner's sealed paper was opened, and it was found that his vote was given in favour of Dr. Simpson. Dr. Matthews Duncan and Dr. Simpson having each three votes, and Dr. Keiller only one, Bailie Russell withdrew his amendment,

and gave his vote for Dr. Simpson, who was thus elected by four to three votes. A large number of students waited outside the door of the Court-room while the election was going on, and the announcement of the result was received by them with very decided tokens of disapprobation.

The following requisition to Dr. Alexander R. Simpson, who was recently elected Professor of Midwifery in the University of Edinburgh, has been numerously signed :—"We, the undersigned medical graduates and students in the University of Edinburgh, think it would be a becoming act on your part—considering the feeling in the Profession and among the students against your recent election to the Chair of Midwifery in this University—to resign the same, feeling that your appointment is detrimental to the University and to your own personal interests ; and that this act would be at once graceful and do more to hand your name down to posterity with respect and esteem than the fact of your having been Professor of Midwifery in the University of Edinburgh." We also understand that a requisition to Dr. Matthews Duncan, to give a six months' winter course of lectures on Midwifery, in order that his students may be qualified for examination before the University Board, is in the course of signature, and that nearly three hundred names have already been appended to it.

MR. SYME.

If an Edinburgh graduate were asked to enumerate the celebrated men who, during the last thirty years, had best served to maintain the reputation of that city as a school of medicine, distinguished above every other in Europe, the name which would first occur to his mind, and to which he would give articulate expression, would be that of Professor Syme. In doing so he would be influenced by those feelings of profound admiration and respect which, from the moment on entering his class-room, Mr. Syme inspired in the minds of his students—impressions which time only served to increase, as the value of the instruction then received became more fully understood. Others, by a more brilliant display of genius, may have won for the University of Edinburgh a greater amount of popular renown, but none have ever surpassed, or, more correctly, have ever equalled him in the influence for good which he has exercised through his pupils over the whole civilized world, or in establishing upon a firm basis the science and art which he professed.

Mr. Syme was born in Edinburgh on the 7th November, 1799, being the younger son of John Syme, Esq., of Cartmore and Lochore, the representative of a highly respectable Fifeshire family. His elder brother, who survives him, is David Syme, Esq., of Warnoch, a deputy-lieutenant and sheriff substitute for the county of Kinross. Mr. Syme received his early education at the High School, and in the very building which afterwards formed a part of the Royal Infirmary, an institution he was destined to render so famous. From the High School he passed to the University, where, besides prosecuting his literary studies, he devoted considerable attention to the study of chemistry, one result of which was his discovery, at the age of seventeen, of the method of rendering cloth waterproof by caoutchouc in solution. An account of this he himself has given in a short paper annexed to his work entitled "Contributions to Pathology and Practice of Surgery." Entering upon his professional studies, he soon after was entrusted by Mr. Liston, who was then teaching anatomy, with the charge of his dissecting rooms, and, on Mr. Liston ceasing to lecture on that subject, in 1822, he was succeeded by Mr. Syme, who was then only twenty-two years of age. Three years afterwards he commenced a course of "Lectures on Systematic Surgery," and, notwithstanding that Liston, Lizars, and Fergusson were also lecturing on the same subject, his class-room was crowded, frequently numbering upwards of 200 students. We have before us his "Syllabus of Lectures," published in 1831, which corresponds in every particular with the plan on which his "Principles of Surgery" is based—a work which has reached a fifth edition, and which for vigour, lucidity, and graphicness of detail is unequalled in medical literature. Failing to obtain an appointment in connection with the surgical staff of the Royal Infirmary, Mr. Syme opened a private surgical hospital in Minto House, the expense of maintaining which was defrayed, in a great measure, by the fees he derived from those gentlemen who, under the name of apprentices, acted as his assistants. In this hospital, in 1829, was instituted for the first time in Britain a system of clinical instruction which it is impossible too highly to characterise. There are thousands living who can bear witness to its matchless success. The bold course which Mr. Syme then adopted was characteristic of his whole life. Surrounded as he was by opponents of acknowledged eminence in surgery, no undertaking could have been more difficult or dangerous than that he then accomplished—one from which men of lesser genius and greater ambition would have shrunk, or in attempting would have failed. The motives which actuated Mr. Syme were doubtless those by which he was ever distinguished, the desire of honestly discharging duty, and a manly consciousness of his own ability to do so.

In 1833 the Professorship of Clinical Surgery in the University becoming vacant, he was appointed to the chair, and as the system of clinical instruction which he had introduced could be carried out only within the walls of a hospital, accommodation was afforded him by the managers of the Royal Infirmary for that purpose.

On the death of Professor Liston, in 1847, the Council of University College, London, appointed Mr. Syme their Professor of Clinical Surgery, an honour he was led to accept from the strong desire he felt to introduce into the London school his system of instruction. The reception he met with from the students attending that University was enthusiastic, and his success as a teacher of clinical surgery was as highly appreciated in London as it had been in Edinburgh. Finding, however, that he was expected to deliver lectures on systematic as well as on clinical surgery, he resigned the appointment, which he had held only a few months, and returned to Edinburgh in July, 1849, when he was shortly afterwards re-elected Professor of Clinical Surgery. Mr. Syme's action in this matter was singularly in keeping with his whole life. The duties he undertook in London he knew his own ability thoroughly to discharge ; those which in addition he found unexpectedly imposed upon him he felt he could not, with his other engagements, fulfil to his own satisfaction ; and, with his characteristic horror of anything approaching sham, he retired from a position which he alone thought he was unable to occupy.

From 1849 to 1869 Mr. Syme held the chair of Clinical Surgery in the University of Edinburgh. The principles upon which the course was conducted were thus given by himself :—"The objects of this course are to teach the discrimination of surgical diseases by pointing out their distinctive characteristics in the living body, and to impress the principles of treatment by showing their application in practice. With these views, all the patients whose cases come under consideration are placed before the students in the theatre of the hospital, when, with due regard to their feelings, the opinions entertained as to the seat and nature of the malady are freely expressed, and the means of remedy deemed requisite are administered either at the same time or upon some other more convenient occasion." The cases seen were all new, being selected from among the patients who happened to be in the waiting-room on the days of lecture. It was then his extraordinary diagnostic powers were seen to greatest advantage, and few, if any, can recall an occasion in which his opinion was not confirmed by the result of immediate operation or more prolonged treatment. His statement of the reasons which guided his judgment, and determined his method of treatment, was always clear and explicit, and never failed

to convince; and, although conveyed in language of singular conciseness, was intelligible even to the youngest of his students.

In operating, Mr. Syme, as might be expected from his general character, never displayed any brilliancy in style; the interests of the patient before him alone occupied his attention. Having determined on what was to be done, he did it with a dexterity that has never been surpassed; and his clear judgment enabled him to meet any emergency with calmness and decision.

It is impossible to attempt within the limits of a notice such as this an estimate of the work Mr. Syme accomplished. To him we are indebted for placing among the regular operations of surgery the excision of joints; for the operation of amputation at the ankle-joint, which bears his name; for the treatment of stricture of the urethra by external incision; and for our knowledge of the pathological condition and appropriate treatment of many formerly obscure diseases of the rectum. These are a few from among the many labours Mr. Syme achieved, and are selected because on each he wrote at some length.

As a medical reformer Mr. Syme occupied a prominent position, and the weight attached to his views was evinced by the fact that, but for his sudden indisposition last year, he would have been appointed President of the General Medical Council. His last literary effort was expended on this subject.

The most striking feature in his character was his blunt honesty, which sometimes manifested itself in a way not pleasant to others or advantageous to himself.

In controversy he was a dangerous opponent from the logical force of his strong common sense. Whatever cause he espoused he did so from the firm conviction that it was on the side of truth.

The many honours which were paid to Mr. Syme by academic and scientific bodies were exactly suited to his own desires; others, bringing with them greater notoriety, he might have possessed had he cared to accept them.

After a life of active usefulness of more than usual duration, Mr. Syme died on the evening of June the 26th, leaving behind him a reputation second to none, and which will endure as long as the healing art itself.

A HOMŒOPATHIC CHALLENGE OF PRIORITY IN THE DISCOVERY OF CHLOROFORM.

The *Monthly Homœopathic Review* publishes the following narrative of the discovery of chloroform which, it says, may be relied on as correct:—

Shortly after sulphuric ether had begun to be used for producing insensibility to pain during operations, it was, by way of amusement, tried one evening on a number of persons assembled at the house of Mr. Walker, homœopathic chemist, then residing in Liverpool, but now of Conduit street, London. It was found to be long in producing any marked effect, and in most cases was followed by sickness and vertigo. The operator was Mr. Waldie, the analytical chemist at the Liverpool Apothecaries' Company, and to him Mr. Walker remarked, that as chloric ether, when administered internally, was preferred to sulphuric ether in many cases, because of its not producing sickness and headache, no doubt it would prove a better anæsthetic; and that if found not to be strong enough, chloroform, from which it is made by dilution with alcohol, would certainly have the same properties, and should be tried. The experiment would have been made there and then, but the hour was late and the laboratory of the hall shut up, so that no chloroform could be obtained. It would have been useless to have tried elsewhere for it, as at that time it was used only for making chloric ether, and nearly all of that medicine used in Liverpool was made in the Apothecaries' Hall.

About a month after this conversation Mr. Waldie had occasion to visit Edinburgh, and called on Professor Simpson, whom he found experimenting on various gases as a substitute for sulphuric ether, which he also had found very imperfect in its operation. Mr. Waldie then mentioned that he had thought of trying chloroform, and, as none could be found in Edinburgh, he promised to make some and forward it as soon as he returned to Liverpool. Professor Simpson, however, with his accustomed energy, at once set to work and had some made by his neighbours, the Messrs. Smith, chemists, and Mr. Waldie had scarcely reached home when he received a pamphlet giving the result of numerous successful trials made with it.

WEDNESDAY, JULY 13, 1870.

THE BILL AND THE COMMONS.

That the Medical Bill has been smuggled through th House of Lords our readers have already been apprised. We say smuggled deliberately, for it is manifest that the Government, as represented by the Privy Council, has purposely betrayed the Profession. It was thought by many that the bill was introduced into the Upper House first, in order that it might receive from the Peers all the attention it deserved, and so go down to the Lower House as a carefully digested measure that would content the Profession. But the event has proved otherwise. A foregone conclusion of the *quidnuncs* who can earwig the Privy Council has been pushed in an indecent manner through the Lords, and, as if not satisfied with carrying his ridiculous bill, Earl de Grey has deliberately insulted the 20,000 practitioners by sneering at their capacity for self-government. Still we do not despair. In spite of official arrogance, good sense and justice have raised their voices, and the echo will yet be heard in the Lower House.

We tender hearty thanks to the Marquis of Clanricarde for the stand he made on behalf of the right of the Profession to be represented in the Medical Council, which

costs it so dearly in honour and in cash. Unhappily his opposition was too late, and it came after a weary debate on the Irish Land Bill, so that Earl de Grey managed to get his way. To the Earl of Lichfield, too, we owe thanks. He brought forward, though also at a late period, an amendment in favour of direct representation. That one word *direct* defeated him. He had evidently taken his cue from the clique that rule the British Medical Association in a manner that their own agitation most thoroughly condemns. Had he merely asked for representation, we have reason to think Lord de Grey, with all his insensibility to the claims of true liberal thought, would have hesitated to refuse. At any rate this good has been gained—the bill will come to the Commons laden with the verdict of several enlightened Peers in favour of self-government for the Profession. The nonsense about want of machinery will go for nothing in the presence of members elected by University constituencies. They will at once point out that the same machinery by which they are elected is available for electing members of the Medical Council; and surely it is no insurmountable task to model a similar machinery for each of the other corporations. A single clause directing the members of the Medical Council to be elected by the holders of the diplomas of the several bodies would give the Profession a representation that would at once change the aspect of affairs. Much mischief has been done by the advocates of *direct* representation repudiating what they are pleased to call the *indirect* method. Away with these internal jealousies, and let all unite to demand representation simply. The *method* can be debated when the principle is conceded. The clique that governs the British Medical Association has been guilty of a great breach of trust in this matter. It has done its best to stifle what it has not yet adopted, and has concealed the fact that it was ordered to ask for the plan it has scarcely the hardihood to claim as its own, though the manner in which it assumes to have originated the direct plan is too much for the gravity of any reformer of ten years' standing.

Away, then, with this indecent jealousy, and let all unite in the single cry for representation in the Council that squanders the money of medical practitioners whom it neither protects nor respects. The one other point—the one-portal system. Without that the bill is useless. It will meet in the Commons Sir John Gray's bill. When the two are discussed together, we hope this will be insisted on. We want no triple-headed monster, and, rather than have the three new boards, we would go on as we are. Amalgamation is proceeding voluntarily. The corporations have nearly established a system as good as that of the Government bill, and, if let alone for another year, will complete it. Rather, then, than take the miserable abortion offered us by Government, let us wait another year. We call upon all our readers to use their influence towards this end. Ten thousand practitioners have signed a memorial that has been treated with contumely. Let each of these ten thousand write to the representative of his borough or county, and to every other M.P. he knows, explaining and urging the points we have laid down in this article, and we predict that the bill will either be abandoned or so changed as to give satisfaction. Perhaps it would be best for it to be abandoned to the "slaughter of the innocents." Not that it is "innocent." It is as clumsy an attempt to effect by elaborate contrivances what might be done in the simplest manner as ever disgraced a Government office—as outrageous a perpetuation of oligarchical mischief as ever emanated from a bureaucratic centre. And this from a Liberal Government! Why, the most fervent worshipper of the past would sweep away the dust that is here preserved as a relic. The defenders of centralization, the apologists of despotism itself, would never stand godfathers to such a measure. Let us, then, with one voice repudiate. We have asked for bread, and are offered a stone; we have expected a fish, and lo! a serpent is presented to us.

We repeat the bill is utterly bad, and the whole Profession should at once act. "A good measure, or nothing," should be our cry. Let the table of the House groan under the weight of petitions; let members feel that they must reject such tinkering as this, or be prepared at the next election to be themselves rejected.

SURGEONS AND RAILWAY COMPANIES.

Several months ago, in the columns of The Medical Press, we had occasion to refer to the manner in which surgeons engaged by persons injured in railway travelling, and whose accounts are subsequently paid by the company, should act. We tried then to show that a railway accident ought not to be viewed in the light of a God-send, that no unprofessional conspiracy should be entered into between patient and doctor, and that no railway company should be dishonestly or unfairly mulcted. These remarks are forced upon us owing to an unhappy circumstance which has lately occurred in an English town. The particulars of the case are not yet made public, but private information has reached us which clearly proves the importance of the precepts we tried to teach our brethren. A person feigned to be injured at the time of a trivial railway accident; a certain surgeon, who is now forced to fly the country and for whose apprehension a handsome reward is offered, entered into such an understanding with his patient that the company was heavily mulcted. Subsequent events proved that the man, who was a maligner, deceived the company, and that the surgeon was in the habit of hunting up railway accident cases, entering into arrangements with them to be paid 5 *per cent.* on the amount obtained, with his own bill, which was usually *un*usually heavy. This surgeon wandered far to look after such patients, and is now forced to wander farther that the law may not reach himself. As a preliminary the patient in the present instance, who spent the moneys obtained and which he has not had to refund, is arrested, and we believe bail has been refused for his liberation.

Lately, our attention has been directed to other cases wherein heavy bills have been charged by surgeons, because they feel a railway company can afford to pay. We yield this and no more, that a railway company should be viewed in the light of a rich patient whom it is desirable to retain and not offend by dishonourable means nor dishonest actions, that fair charges should be made for work done, and that the object should not be to bleed unduly. In this, however, we fear, although our Profession as a body is honourable, that there will still be found men ready to do the dirty action, and thus bring dishonour on our calling. That the individual who boasts getting or having obtained heavy verdicts for his patient may be deprived of the power, and that railway companies may be saved unfair

charges, we suggest that in each town and village one of the most respectable and trustworthy of the practitioners should be named to look after all patients of the company in his district, and that, should another practitioner come in before him, both should continue in attendance so long as they are in harmony; but that if the company is subsequently to pay the doctor, and the patient has no particular choice, the medical nominee of the company should go on with the case; on the other hand, should the patient consider his case made lightly of, and appear to his relatives more serious than the doctor acting for the company considers, that he or they be at perfect liberty to call in further advice. This is not likely often to occur if the gentleman chosen by the company be one of reputed honour and skill in the district in which he practises. The patient it is who makes in all these cases the mountain of the molehill, and we sympathise with many companies who have recently been severely mulcted. Juries appear to have little sympathy for them if we may judge of the sweeping verdicts at times awarded. Honesty is the best policy in this as in other matters, and we think the Profession cannot be too cautious in dealing with them. If, as we have just stated, railway companies be considered in the light of rich and influential patients whose patronage we desire to retain, there is nothing to fear; but if, on the other hand, conspiracies are entered into, sooner or later the disgrace comes out, and punishment is the result and the reward.

Notes on Current Topics.

Deductions from the Income-tax of Medical Men.

At the Quarter Sessions recently held in Ennis, the Chairman pronounced a decision which is very important, and which to some may appear novel and extraordinary. It appears that the Income-tax Commissioners, in assessing the professional income of Dr. Cullinan, allowed him to make deductions for the keeping and maintaining of two horses, but they refused to allow any deduction for keeping a groom or coachman. Dr. Cullinan, whose servant is exclusively an outside servant, appealed from the Commissioners to Mr. O'Shaughnessy (the chairman), who dismissed the appeal, his interpretation of the law being such, that if any medical officer to a dispensary, or any physician connected with any public institution (who by law are allowed to make deductions for the keeping and maintaining a horse when necessary for the performance of their duty), drives even once to dine with a friend, or to vote at an election, or to do any other act not strictly professional and official, he forfeits the privilege of making any deduction whatsoever for either horse or servant. In Dr. Cullinan's case the arrangement appears the more extraordinary and illogical, because he is allowed to deduct for the horses but not for the servant, though the same law and principle obviously apply to both. Dr. Cullinan seems to consider the interpretation of the law in this case as not only repugnant to reason, but also contrary to the spirit and words of the Act of Parliament; but, as it appears that there is no appeal from the learned Chairman's decision, we do not see where he is to look for a remedy.

The Prospects of the Vaccino-phobia Agitation.

We observe with much satisfaction that even in its stronghold the vaccino-phobia agitation is in a very melancholy condition of development. Whether it be in money or influence, its progress has been by no means encouraging to the foolish people who have identified themselves with it; and, if the pressure of steam which its stump orators have been able to get up may be estimated from their own representation, the public have need to give themselves very little trouble about the matter.

The first annual meeting of the members of the Manchester Anti-Vaccination League was held last week. From the report for the past year it appears that the outlay has been £51, the income £31, leaving £20 due to the hon. secretary. A letter had also been received from the Bishop of Manchester, in which his lordship said, "The vaccination question must become one of primary sanitary importance, if the facts alleged can be substantiated. They do not, however, prove to my mind that vaccination is mischievous—indeed, its benefits appear to me to be established by an overwhelming weight of evidence—but simply that the vaccine lymph is often poisoned, in which case, of course, it must be mischievous, and may be fatally mischievous."

We wish the Bishop of Manchester, who appears to have been adopted by the vaccino-maniacs as a disciple, could convey a little of his own good sense into his hare-brained patrons. Truly, "*if* the facts alleged by them could be substantiated, the vaccination question must become one of primary sanitary importance."

In these days, when the most solemn and cardinal questions are settled, in and out of Parliament, by agitation and by the lavish use of talk and ink, it is instructive to contemplate the upshot of the vaccination craze. One of the most important of our means of sanitation has been discredited, and doubts thrown upon its efficiency, which it will take years to remove; those earnest in guarding the public health have been troubled to counteract the attack, and even the Legislature has been moved in the matter; and by whom? By a few loquacious and self-conceited meddlers, who, it now appears, are utterly insignificant either in rank, money, influence, or sense. Let it be remembered that paper, ink, and garrulity are at all times within the reach of every agitator who thirsts for notoriety or for subscriptions, and let us learn therefrom to pass in silent contempt the agitation of such persons, unless we can find in it convincing facts, sound argument, and the acquiescence of educated and thinking men.

Summer Diarrhœa.

A contemporary noticing that cholera has already figured in the returns of London, that the late Lord Clarendon died from diarrhœa, and that this last disease is on the increase in London, while last year it nearly deprived us of the Premier, goes on to say that "it behoves the Profession to submit to searching examination the newly projected theory" respecting the causes and treatment of this insidious malady. The writer speaks then of Dr. Chapman's theory, well known to our own readers, observing that "one of the most eminent pathologists of the present day" has announced it to be not only "in harmony with the results of the most recent physiological discoveries," but further a "consistent and intelligible

explanation" of the phenomena of the disease. In Dr. Chapman's work on Cholera the theory is very fully explained, and the treatment by ice to the spine illustrated by numerous cases. At this season that those who have not yet tried the method may advantageously consult the work we have named.

The Small-Pox Epidemic in Paris.

On Monday week last a meeting took place between the Ministers of the Interior and of Agriculture, the Prefect of the Seine, the Prefect of Police, and M. Tardieu, President of the Committee on Public Health, for the purpose of concerting new measures for the mitigation of the epidemic which afflicts the capital. It was resolved that an urgent application be made to the Academy of Medicine that they shall address the public in favour of the pressing necessity for re-vaccination. This demand, being brought before the Academy, resulted in the appointment of a Committee, composed of MM. Depaul, Tardieu, Behier, and Fauvel. The Committee held a meeting at once, and an hour afterwards submitted to the Academy a provisional address, which they recommend it to adopt unanimously. The Academy of Medicine has given an example of zeal and celerity which we recommend to the attention of officials at our side of the English Channel. Within a few hours the proclamation was in course of extensive circulation.

How many sheets of foolscap would be spoiled? how many days or weeks wasted? how many journeys from post to pillar undertaken? and how much money spent in the achievement of so much work by an English Government Department? The negotiations would probably outlive the epidemic.

Hold! St. Pancras.

It is rumoured in the parish that our last week's remarks under this head have not been without effect on the minds of some, and that consequently the mischief is postponed, if not stopped. We hope this may prove true, and that thus reason may prevail.

Utilization of Sewage.

We understand that the authorities of Southampton, profiting by the example set them at Hastings, have determined to adopt the A B C process of utilizing the sewage of their town, and thus to preserve the local waters and beach from pollution. Any doubt that may exist as to the sufficiency of this process for purifying sewage water so as to render it fit to be discharged into rivers, cannot apply to the waters discharged into the sea.

Black Death in Georgia.

One hundred and fifteen persons died with cerebro-spinal meningitis in Coffee county, Georgia, in the month of March. Malignant epidemics of this disease are prevailing, besides, in parts of Mississippi, Florida, South Carolina, and Pennsylvania.

Royal Bounty.

An example for the imitation of all Sovereigns has been given by the King of Italy. There was much wanting in Florence an hospital for the blind. Victor Emmanuel has generously applied the 45,000 francs which were to have been applied to the purchase of a royal crown to the foundation of such an institution. His Majesty has also sent 5,000 francs to the Children's Ophthalmic Hospital, founded at Turin by M. Sperino.

The Medical Club.

This afternoon (Wednesday), at 3 p.m., there is an adjourned special meeting at the Medical Club, to which we hope all members will go who possibly can. The existence of the Club is at stake. With the present rate of subscription, and the present expenses, it will be impossible to continue, and the members should therefore resolve at once what course to take. The Profession ought to have a Club, and we trust some mode of maintaining it may be adopted. Either an increase of subscription or a diminution of rent (which means of comfort also) seems the natural conclusion, unless a large increase of members could be obtained. That, of course, would be the best of all.

A new Swimming Bath.

The Russians are said to pass directly from the Sudatorium into the open air and roll themselves in the snow. The hydropathist boasts of the wondrous stimulant powers of the alternate hot and cold douche; and physicians have recourse to the hot-water bag and ice-bag alternately with much confidence. Doubtless the tonic influence of cold water is heightened and its safety increased by the previous use of warmth, and for general purposes a cold plunge bath in close vicinity to a tepid bath is a desideratum. Mr. Charles Herrman, of Croydon, a Fellow of the Institute of Architects, has devised such a bath, we think, very successfully. It consists of a small central tepid bath, containing 30,000 gallons of water, the boxes surrounding which open posteriorly on a much larger cold swimming bath; so that, after a tepid bath, the swimmer has only to pass through his box for a cold plunge.

Contagious Diseases Acts.

We hear that the Government Commission, shortly to be appointed for the investigation of these Acts, is likely to be a large and popular one, comprising members of both Associations for and against the carrying out of the Acts. The Association against the Acts in London has recently determined to merge itself into the ranks of the National Association, and have a paid secretary in London to manage the affairs of this gigantic agitation. We trust sincerely that the Association may not fall too much into the hands of the evangelical or ultra-religious party: in this country they are the greatest foes to all enlightened endeavours to improve the condition of the unfortunate and degraded, or to offer any remedy for suffering.

The Brighton Aquarium Company.

The Brighton Aquarium Company, for which a special Act of Parliament was obtained last session, is about to erect on a large scale an aquarium at Brighton. The site of the aquarium commences at the toll-house of the Chain pier, and extends to within a few yards of that structure, and will be nearly half the length of the main building of the Crystal Palace, Sydenham, and 100 feet in width. Besides the aquarium, in which will be found tanks ranged on both sides of the vast hall, and of a size to contain the largest specimens, there will be above the hall grounds

laid out as a promenade, furnished with ferns and plants. In addition to these, there will be attached to the building an entrance court. Outside the aquarium will be arranged terrace and garden walks, bounded on the south side by a sea wall and approach road; these, overlooking the sea, will form a promenade ground.

The Corporation of Brighton has, in accordance with the special Parliamentary powers furnished to it in the Company's Act of Parliament, agreed to contribute a cash subscription or free gift to the Company of £7,000. Great success has attended the establishment of aquaria on the Continent; and at Hamburg, under the management of Mr. Lloyd, the resident manager of this Company, the shareholders received back in dividends in two years the whole of the capital they had paid; and it is most likely that a properly managed aquarium, constantly supplied with interesting specimens—of which there are thousands totally unknown, even to the most scientific men—is sure to prove an object of the greatest attraction to all classes of society, and be highly remunerative to the shareholders. The capital of the Company is fixed by Act of Parliament at £40,000 in shares and £10,000 in debentures, with power to increase by £10,000 in shares and £2,500 in debentures. An estimate in detail of the anticipated income appended, promises a net revenue of £11,310, which, on the share capital of £40,000, now to be issued, after paying debenture interest, shows a dividend of over 25 per cent. per annum. A contract for the erection of the aquarium, the building of the sea wall, and laying out of the grounds, &c., has been entered into, by the terms of which the aquarium is to be open for the admission of the public by the 31st December, 1870, and the whole of the works completed by the 1st July, 1871. The important post of manager has been filled by the election of Mr. W. A. Lloyd to that office. He has been engaged on the Hamburg aquarium from its commencement, and it is under his able management that the shareholders of that undertaking have had such very favourable returns made to them.

Post-Mortem Examinations.

Dr. John C. Steele, the Medical Superintendent of Guy's Hospital, was summoned before Mr. Benson a few days ago under the Anatomy Act (2 and 3 William IV., cap. 75, sec. 7), for unlawfully causing the body of William Millbourne to undergo anatomical examination without the permission of the person having legal possession of it.

The case has an important medico-legal bearing. We believe, with Dr. Steele, the Act was passed for special purposes. "At all public institutions, such as charitable places and union workhouses, the medical authorities had power to make pathological examinations to meet the requirements of the Registrar-General." Dr. Steele tells us, *it would have been impossible to know the cause of death in the present case unless a* post-mortem *had been made.* Now, the Registrar-General exacts accuracy. With all respect to Mr. Benson, we do not believe the case comes under the provisions of the Anatomical Act. The majority of patients and their friends know the rules of the hospitals before entering them. Pathological investigation would suddenly stop short if we are to be denied *post-mortem* examinations. An Irishwoman, a few years ago, gave liberty for a *post-mortem* examination to be made upon her son, who died of an obscure complaint, "because," she said, "I may get the same disease myself, and they'll know now about treating it;" but, after the examination was concluded, she bitterly lamented the fact, and by her affected lamentations drew a crowd round her, whom she informed the hospital authorities stole "the lights and livers of her poor Jack, and stuffed him with straw," in order to excite sympathy. Has the present case cropped forth for the same purpose? We think, in the instance before us, had Mr. Carter Millbourne spent upon his father, during his lifetime, the money which he, or somebody else, must find to pay lawyers, that it would have reflected more to his credit or theirs than in bringing into court for investigation the particulars of a case which cannot injure the authorities of Guy's, or break through the existing rules of our noble institutions.

Dissection in Hospitals.

A question has been litigated in the London Police Courts, which is of very great interest to the Profession, and which appears difficult of solution in any way which shall at the same time preserve public benefits and respect private feelings.

At Southwark Police Court, Mr. John Charles Steele, M.R.C.S., and superintendent of Guy's Hospital, was summoned before Mr. Benson, under the Anatomy Act (2 and 3 William IV., cap. 75, sec. 7), for unlawfully causing the body of Samuel Millbourne to undergo anatomical examination, without the permission of the person having legal possession of it. Mr. Carter Millbourne, son of the deceased, and the complainant, said that on the 1st of June he took his father to Guy's Hospital. On Thursday morning, the 16th, he was alive, but fast sinking. Witness saw him again at four in the afternoon, and remained with him until his death, about 5 o'clock. He saw the nurse and sister of the ward, and desired to take the body away then, but the latter told him he could not remove it without an order from the steward, who would not be in attendance until after 9 o'clock the next morning. She also told him that the house surgeon might wish to make a *post-mortem* examination. Witness informed her he could not consent to that without mentioning the circumstances to the other members of the family. Witness left the hospital at half-past 5, and next morning, at 20 minutes past 9, he called and saw Dr. Steele, and told him he had come to claim the body of his father, but it was not brought until seven in the evening, and then it was in a coffin, cut up in the most shameful manner. Witness proceeded to the hospital on Saturday morning, the 18th, and saw Dr. Steele, who told him it was done without his knowledge. He sent for some one to ask about the *post-mortem* examination. That person said, "Yes; there was a complete *post-mortem* examination. The brain was removed, as well as the windpipe, heart, &c." Dr. Steele said the Act was made for special purposes. At public institutions, such as charitable places and union workhouses, the medical authorities had power to make pathological examinations to meet the requirements of the Registrar-General. It would have been impossible to know the cause of death in the present case unless a *post-mortem* examination were made. An anatomical examination was merely cutting a body up for the students. Mr. Thomas H. R. Hooper, M.R.C.S., Blue Anchor road, said that on Sunday, the 19th ult., he was called in by last witness to see the corpse of his father. He examined it, and found it cut about as though an hospital *post-mortem* examination had been made. The cause

of death was stricture, and there was no occasion to remove the brain. Dr. Steele said that the disease might extend to the brain, and it was necessary to open the head to ascertain the cause of death. Mr. Benson here observed that, according to the evidence, it was a question for further investigation whether it did not come under the Anatomical Act. Mr. Benson was of opinion that when a body was claimed by the relatives, and they had arranged to take it away, the hospital authorities had no right to cut it about without their authority. There were some points of law of vast importance to both sides, and therefore he should adjourn the case to give the hospital authorities an opportunity of consulting with their legal adviser.

The question is one which we think ought not to be regarded from a medical point of view, for it cannot be maintained that the fact that a patient dies in hospital, instead of his own home, confers any right to interfere with his body. The sick poor, in availing themselves of charitable relief, do not in any respect surrender their rights, and it would be a subject for great regret if the feeling of distrust which often leads relatives to remove the patient when in *articulo mortis* should be intensified by imposition of any legal disability on them. However unfortunate it might be that obscure causes of death should remain undiscovered, and that relatives should act churlishly in the matter, it would be utterly improper for the Profession to obtain its information by an infraction of their rights and utterly indefensible to do so for any other purpose than the essential investigation of the individual case.

Royal College of Surgeons of England.

The Council adjourned the election of a representative in the Medical Council until to-morrow (Thursday), the 14th. Mr. Hawkins does not wish to be re-elected. It is said Mr. Quain did not attend the last meeting, as he expected to be appointed. Once more, we ask the Council not to usurp the right of appointment. The Fellows and Members constitute the Corporation, and Mr. Cock will forfeit all the goodwill he has elicited if he does not call another meeting to discuss this question. There is no need for hurry, and the man who rushes into the vacant place must expect to be covered with the anger of the whole body of Fellows and Members. If he pretend to speak in their name, he will be a mere impostor.

The New Councillors of the College of Surgeons.

Professor Erasmus Wilson and Mr. Henry Lee were elected by the Fellows on Thursday last; the former polling 121 votes, and the latter 112. Messrs. Spencer, Wells, and Holmes Coote each polled 80 votes. We congratulate the successful candidates, and venture to offer them a suggestion. If they take their seats at the special meeting to-morrow, let them assert the rights of Fellows and Members to elect the representative of the College in the Medical Council. One of them we know holds our views on this subject—perhaps both. If so, they will prove a valuable reinforcement of the Council. Mr. Cock will surely call the meeting he was asked to do, and let the Council postpone any appointment until after such a meeting; and we shall see the result. It is now come to such a pass that every one seeking election into the Council must be judged by this one test.

The Edinburgh Appointment.

A meeting was called for Monday night, in London, to discuss the appointment of a successor to Sir J. Simpson. Though our report is not ready, we may remark that the feeling must be strong which leads to a protest in London against an Edinburgh appointment. There seems little doubt that Dr. Simpson would have had no chance had he not been the nephew of Sir James, and as little that this is a sorry way of honouring the deceased. We leave the ferment occasioned in the north to our Scotch editor; but speaking as Englishmen, unknown to any of the parties, we cannot but say we agree with our Edinburgh contemporary. To us the lesson of this scandal is that it illustrates the absurdity of placing the patronage of University chairs in such hands, though it would not be easy to provide a perfect electoral body. Some recent appointments at London hospitals and colleges have been made in quite as scandalous a manner, although we have nothing to urge against the persons selected.

In a University is there no way of entrusting the election to the most distinguished graduates in the faculty in which the vacancy occurs? There are objections, no doubt, to such a course, but a popular body could not be worse than six or seven town councillors. Fancy the Lord Mayor and three aldermen being allowed to elect hospital physicians and teachers in our medical schools!

Medical Cross-Swearing.

The unreliability of partizan medical evidence in Courts of Law has been very forcibly brought under the attention of a Committee of the House of Commons by Mr. Baron Martin, and we trust that some steps will be taken to provide for the assistance of judges by disinterested medical assessors. In the Admiralty and other Courts provision is made to enable the judge to arrive at a fair conclusion on points respecting which he cannot be expected to be correctly informed, and it is ridiculous that any non-professional arbitrator should be called upon, as are the judges in railway compensation cases, to strike a balance between the opposition swearing of rival doctors. Under the regulations of the Railways Act power is given to the Court to order an examination by an assessor, but the provision has not been made use of, in consequence, we presume, of some technical difficulty.

If the Committee should arrive at any conclusion which will discourage cross-swearing amongst members of our Profession, it will contribute materially to its dignity, and we shall be glad to be spared the spectacle now so frequent of medical witnesses swearing black white against each other, and receiving from judges and juries not the least credence or consideration.

Mussel-Eating.

It is surprising the quantity of mussels imported into our manufacturing towns. The working-man appears to feast upon this shell-fish with a marked preference, if we may judge of the large consumption of it. A visit to the markets of Manchester and like towns will reveal the fact that mussels were largely sought after and eaten by the manufacturing class at a time of year when some restriction should be placed upon their sale, for during the months of May, June, and July they are a dangerous commodity, not having recovered from the effects of spawning, and in many instances produce serious mis-

chief. We have lately observed the grave results which arise from a careless indulgence in mussels, from the general rash over the surface of the body—so characteristic of unwholesome fish—to the protracted, and, in some cases, fatal diarrhœa. In France, where mussel-farming is cultivated with the same care as that of oysters, and where they are placed under the operation of the fishery laws, we find, during four summer months, no mussels are sold for consumption in the markets or shops. Even if they were, they would not be so dangerous as the large fat mussel to be found in our markets, and consumed with so much recklessness as to future suffering by the working-man. Disease is engendered and propagated through the carelessness with which the dietary of our people is managed, and serious epidemics arise through incaution. Accordingly we believe it should fall to the duty of all inspectors of markets to prohibit the sale of unseasonable articles of food. How often do we see lobsters and crabs vended, at a time when they are most baneful; and how frequently are our professional services required to minister to suffering arising from the injurious effects of stale or unseasonable shell-fish!

Dr. Brady, M.P., has been appointed a Deputy-Lieutenant for the County of Leitrim.

The Sale of Poisons (Ireland) Bill passed the second reading in the House of Lords on Thursday last.

The amount realised for the sale of the late Charles Dickens's pictures, and other works of art, on Saturday last, was £9,410.

Mr. Stone, the resident surgeon at Christ's Hospital, has just sent in his resignation, after thirty-five years' service.

The Royal Institution of Great Britain has received a legacy from the late Alfred Davis, Esq., for the promotion of experimental researches.

Mr. and Mrs. C. J. Freake have paid the sum of £420 to the treasurers of St. George's Hospital as the proceeds of a concert given by them at Cromwell House, South Kensington.

Nature states that the University of Vienna has decided to admit women to all the advantages of its medical school, and that two French students have already availed themselves of the privilege.

The Lord's Day Rest Association have petitioned the House of Commons—That the employment by the State of upwards of 20,000 persons in the department of the Post Office on the Lord's Day is not justified by public necessity.

Her Majesty the Queen will proceed in state to open the Victoria (Thames) Embankment to-day (Wednesday). This gigantic work is one of the best and most useful specimens of engineering skill in the metropolis.

Mr. Alfred Smee, F.R.S., F.R.C.S., &c., will again contest the seat in Parliament for the city of Rochester, vacant by the death of Mr. Kinglake. We heartily wish our *confrère* success.

Mr. Weeden Cooke has resigned the office of Senior Surgeon to the Royal Free Hospital, held by him for the last twenty years. It is understood Mr. Cooke has been compelled to take this step in consequence of increasing demands on his time in private practice.

M. Taschereau, Director of the Richelieu Library in Paris, has just bought for thirty thousand francs the very rare collection of books, portraits, medallions, &c., relative to Michael de Montaigne, the collection having been made in a period of fifty years by Dr. Payen, of the St. Germain watering-place, in Upper Savoy.

Correspondence.

ENTIRE LOSS OF SPEECH AFTER SMALL-POX.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—From having had, some years back, under my care in hospital a girl aged seventeen who lost her speech after small-pox, and in three months began slowly to regain it, I venture to predict a similar result for Dr. Waring-Curran's case after typhoid fever, recorded in this day's Medical Press and Circular. My patient returned to her service in robust health in every respect, except that she could not emit any sound. From the efforts made to speak, it seemed to be a case of acute balbuties, depending on effusion in the neighbourhood of the medulla oblongata. The chief treatment was blistering the nape of the neck. Yours, &c.,

29, Lower Gardiner street, Dublin. W. B. Peebles.

CONTAGIOUS DISEASES ACTS.

Letter from M. Lefort to Dr. Charles Drysdale (translated).

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The insertion of the following letter from M. Lefort may prove as interesting to some of your readers as it has to myself, and I therefore take the liberty to ask for space for it in your valuable and most catholic and liberal of all medical journals in this country.

I remain, with profound respect, yours faithfully,

Charles R. Drysdale, M.D., M.R.C.P.L., F.R.C.S.E.

2 Rue de l'Université, Paris, 27th June, 1870.

My Dear Colleague,—I have received with great pleasure the number of the Medical Press, and I thank you warmly for your amiable attentions to me. The number of illegitimate children is just as you remark, in the proportion of one illegitimate child against less than three legitimate children; but I do not see that divorce, if made more facile, would change anything in this respect. In fact, if the working man (in France) does not marry, it is not because he fears to undertake an engagement which is with difficulty broken by legal means. The workman fears to give up his liberty, and to fall into misery in giving himself up to nourish a wife and children. He finds a work-girl who consents to be his mistress, he frequents her, but he rarely lives with her. If she becomes pregnant, he quits her without remorse, and seeks for another. The woman, on her side, does not hold out for marriage, because the looseness of morality (*relachement des mœurs*) brings it about that among the working classes there is scarcely any difference made between the legitimate wife and the concubines.

Is it the absence of facility of divorce which has gradually caused this condition of things? I do not think so. The true cause consists in this, that in Catholic societies religion teaches dogmatic morality, but not morality *independent of religion;* when scepticism and free examination have shown all the absurdities of the Catholic religion, the workman, not being sufficiently educated to understand the laws of natural morality, and having abandoned his religion and the morality which rests on divine prescription, has no longer any rule to direct his conduct, except instinct. Between England and France there are profound differences, sometimes to the disfavour of one, sometimes of the other; public opinion is very

different. It is for this reason that it is difficult to judge concerning either people by a citizen of the other ; and, that I may not leave the subject of prostitution, I may observe that a measure which would prove excellent in England would produce no result of utility in France. Such is the principal reason of the divergence of opinion which exists between us on several important points.

Bien à vous,
(Signed) Leon Lefort.

P.S. It seems to me that M. Lefort has quite shown us that the Catholic marriage without divorce is *one* great cause of the illegitimacy of Paris. He says that the workmen have quitted that faith, but have no other. Why, then, does not the French Government endeavour to show them that it holds that faithful domesticity is far more noble than the evanescent unions he says are so common, by giving the sanction of society or natural morality to unions less stringent than the Catholic Church permits—*i. e.*, to marriage with greater facility for divorce.

C. R. D.

THE LATE SIR J. CLARK, BART., M.D., K.C.B., F.R.S.

Another of our veterans have passed away. Although the late Sir James Clark had of late years retired from practice, yet he still remained emphatically the Queen's Physician, taking part as Her Majesty's senior medical adviser and friend in all consultations, and frequently alone in attendance. He was born in December, 1788, and so had nearly reached the age of 82. He went to Aberdeen, entering at King's College, of which subsequently he was M.A. From thence he went to Edinburgh. He entered the Navy as assistant surgeon, but in 1815 he left the Service and resumed medical studies at Edinburgh, where he graduated M.D. in 1817. Dr. Clark travelled much on the Continent, thus preparing the material for his work on Climate, which appeared in 1828, and has ever since been more or less looked upon as a valuable authority. In spite of all that has since been written on this subject, we constantly find Dr. Clark had anticipated much now offered us as new. Prior to this he had spent eight winters at Rome, where he made the acquaintance of Prince Leopold of Saxe Coburg. It was this which led to his success: that Prince on his settling in England made him his physician, and this led to his succeeding Dr. Maton as physician to the Princess Victoria, so that on Her Majesty's accession to the throne he was gazetted as first physician to the Queen. In his work on Climate he ably set forth the claims of the Isle of Wight as a health resort, and the Undercliff, which he particularly pointed out, is still looked upon by many as more adapted for English invalids than any Continental winter climate.

Sir James Clark was placed on the Senate of the London University on its foundation, and he took a lively interest in other schemes of an educational kind. In a pamphlet on Clinical Instruction he pointed out many a neglect that has since been remedied in education and examination. He was a thorough medical reformer, a strong advocate of the one-faculty system, a friend of the general practitioner, and an opponent of those corporati on abuses which have so degraded the Profession. When the London College of Physicians, late in the day, offered him its Fellowship, with the true spirit of a reformer he declined the honour of being elected in a manner that has always been unsatisfactory ; consequently, he remained to the last outside the magic list of Fellows—an example we wish a few more would follow. On the change of name of the old Licentiates to the new grade of Member he consented to be thus classed, so in this year's list of the College his name appears as the eleventh in the Members, his date being 1826, and ten others surviving who had joined earlier (from 1814 to 1824). Perhaps his decease among the Members may remind the Fellows of the work that exists outside them, and make them promote the Members a little faster. The only painful part of the late physician's career related to the case of the late Lady Flora Hastings He was much blamed in many quarters, though his friends declared he could clear himself but for his position at Court. Whoever was to blame, there can be little doubt now on any one's mind that Lady Flora was killed by the aspersions cast upon her. It was demonstrated that she never had been pregnant, and yet she had to endure the disgrace that attached to such a charge. It was a sad, sad case, and all who are familiar with the sweet sadness that pervades her poems cannot but keenly feel for the misery that urged her to an early tomb. Innocent, yet knowing that the majority thought her guilty—bearing too with her the load of that disease which simulated pregnancy—she pined away and died—a victim to Court gossip, aided by erroneous diagnosis.

We pass from this to remark that for many years Sir James enjoyed not only the friendship of the Royal Family, but that of many distinguished men in science and literature. Besides his chief work which we have named, and his "Treatise on Consumption and Scrofula," he wrote in the *Cyclopædia of Practical Medicine* and in other quarters. He also took a part in establishing the *Medico-Chirurgical Review*.

He remained to the last interested in his brethren and in many institutions, and belonged to many Societies. He was a Vice president of the Scottish Universities Union, an Association which has thus within so short a time lost two of its Vice-presidents, both of them Baronets, both medical men—the subject of this notice, and the late Sir J. Y. Simpson.

Medical News.

Biennial Festival of the Hospital for Diseases of the Throat.—This Festival was celebrated at the Freemasons' Tavern on June 29th, under the presidency of the Right Hon. the Earl of Powis, who was supported by Lord William Lennox, Rev. Dr. Brock, Rev. H. R. Haweis (chaplain to the Institution), Dr. Morell Makenzie, Dr. Billing, F.R.S., Captain Butler Fellowes, C.B. Rev. Dr. Bell, M.D. and Messrs. Lennox Browne, G. A. Smith and others. In proposing the toast of the evening, "Prosperity to the Hospital for Diseases of the Throat," the noble chairman drew attention to the fact that since the establishment of the hospital in the year 1863, it had relieved upwards of 24,000 poor persons. Many of these had come from the most remote parts of England, on purpose to seek advice at the hospital. The hospital was entirely free to all the necessitous poor of the land, and, having no endowment, it was entirely dependent on voluntary subscriptions for its support. The chairman coupled with this toast the name of Dr. Morell Mackenzie, who was received with the warmest applause when he rose and in a speech that, though short, was well to the point, returned thanks for the hospital and its staff. Dr. Mackenzie briefly narrated the rise and progress of the hospital up to its present condition ; he said what they now wanted was to purchase the freehold of the hospital and get more room for their patients, who were outgrowing the space afforded by the hospital for their accommodation. Dr. Mackenzie fully agreed with the views of Captain Galton that it was a mistake to make a hospital a splendid and costly pile of architecture designed to last to the end of time ; a hospital should rather be a building designed to stand but for a period of years, so that when it became unhealthy from the constant impregnation of its walls and timbers with the exhalations of the sick, it could be pulled down and built up again all fresh and clean. Among other speakers were Mr. Brudenell Carter and Rev. Dr. Bell ; this last gentlemen, touching on special hospitals and specialisms, said that a man to be a really skilled specialist must have a good sound general knowledge first from which his special line of practice gradually developes and becomes prominent. The sum of over 1,000 guineas was subscribed during the evening, and of this the noble chairman contributed 50 guineas, Mr. Crook £50, and several of the City companies and firms gave 10 guineas. A donation was also received from Lord Hyde, though he was not able to be present in person, owing to a well known bereavement in the family.

English Poor-law Medical Officers' Association.—The meeting takes place this evening. From the annual report of the Council to be submitted we learn that one hundred and twenty new members have been enrolled during the year. Several deaths have to be lamented, especially that of the venerated Richard Griffin. The annual balance sheet shows the finances of the Association to be in a healthy condition, the balance of £58 carried forward last year being somewhat increased. The expenditure has been heavy, principally owing to the arrangement entered into with the publishers of the *Poor Law Chronicle* for the supply of that Journal to the members. Your Council express the gratitude of the Medical Officers to the President of the Poor Law Board, to Dr. Brady and the other gentlemen who spoke in support of the Superannuation Bill, and to the 139 who voted in its favour. By this one of the "objects" of the Association, viz., "to obtain superannuation allowances for the Medical Officers," is achieved; Medical Officers are now placed on the same footing as other Poor-law Officers with regard to pension. The Council say they cannot sufficiently express the obligations the Association owes to the medical journals for the constant sympathy and support it has received in their columns.

Novel Method of Illustrating Disease.—On Monday the 4th inst., according to the notice given by this journal, Mr. Balmanno Squire showed his method of demonstrating skin diseases. The room having been darkened, magnified images of the patients themselves were thrown considerably larger than life size on the spacious screen of the theatre by means of the dissolving-views apparatus, so that all the details of the various eruptions were plainly visible even from the most distant parts of the theatre, and were equally discernible by every member of a large audience. Mr. Squire after giving a *resume* of the acknowledged difficulties of imparting a practical knowledge of the medical art to students, proceeded to show, by the crucial test of actual experiment with the examples brought forward how that the method he submitted would dispose at least of the more serious of these difficulties, and explained that it was not only applicable to the department of practice that he himself followed, but was capable of wide extension to the subject of medical education generally. The plan he proposed would, by magnifying the object to be demonstrated, enable every detail of it to be seen by every member of a large class, and to be pointed out to all of them by the lecturer at the time he was describing it. More than this, it was known that, even if disease would consent to stand still in its most instructive phase util the time that it was wanted for the purposes of instruction, common humanity prevented our withholding relief from the sufferer in order that other sufferers might benefit by the instruction to be derived from him. But, by the method proposed, the patient might be instantaneously photographed in his most instructive phase before either the natural progress of his disease or its amelioration under the resources of art has impaired its utility as a means of conveying instruction, and at the same time, in cases where colour formed an important feature of it this could be added to the photograph itself by an expert artist working under the eye of the teacher himself. In the case of cutaneous disease, the most difficult of all subjects to illustrate by these means, colour was certainly a most important feature. But he appealed to those he saw around him, many of whom he knew to be well versed in this special subject, whether the illustration he had brought before them were not in colour as well as in form and shadow sufficiently life-like to afford a lecturer ample opportunity for pointing out to a class of students all the essential peculiarities of each disease and to enable those students when they entered upon private practice to recognise at once the nature of similar cases whenever they might meet with them.

Sunstroke.—The three following deaths have been registered as caused by sunstroke: a butcher, aged 59 years, died on the 23rd June at Middlesex Hospital, of sunstroke; a girl, aged 6 years, died on the 27th of June, at Bethnal Green, after eleven days illness, from the same, and a boy, aged 5 years, died on the 25th of June, at Poplar, "sunstroke (5 days) convulsions."

Apothecaries' Hall, Blackfriars.—At a Court of Examiners, held on Thursday the 30th ult., Mr. F. W. Willmore, Walsall (Birmingham School of Medicine), was admitted a licentiate of the Society of Apothecaries'; the following passed the primary professional examination, viz:—Messrs. J. W. Fordham and Cyrus James, of the London Hospital; J. E. Richards, of University College Hospital; Thomas Strafford, of St. Bartholomew's Hospital; J. M'Dougal Tudge, of Guy's Hospital; and Samuel Wilson, of the Newcastle-upon-Tyne School of Medicine.—The following were admitted Licentiates on the 7th instant:—Frederick Barton, of St. John's Wood; Henry Parmiter, of Dorchester; and William Vickers, of London.

University Life Assurance Society.—The quinquennial statement of this old established Society has just been issued. From it, and from personal knowledge, we gather that it is in a most flourishing condition, and with the uncertainty and want of confidence at present existing with regard to life assurance societies, it is pleasant to turn to such as this. Established in 1825 for, and maintained ever since solely by University men, it is enabled to declare the enormous balance, applicable to quinquennial division, of £166,619. When we consider that this sum represents clear profits over the working expenses of the past five years, and that the insured may take their bonuses without the semblance of doubt as to the legitimacy thereof, or safety of the undertaking, it naturally suggests that the examiners are more particular as to the lives they accept; that university men are longer livers than the general public, and that the basis is sound and the management everything that could be desired.

Cancerous Degeneration of the Stomach and Emphysema Pulmon um, Treated with Oxygen Gas.

The *New York Medical Gazette* reports a case thus:—Mrs. P., aged sixty years, very anæmic; was in December of 1869, attacked with pleuro-pneumonia of the left side. After recovery, the patient began to suffer from frequent vomiting, which occurred once or twice every week without any provocation, as it often took place in the morning before she had eaten anything. She also suffered from constipation, requiring the frequent use of laxatives. There was at times a tenderness of the whole gastric region, but no tumour could be felt anywhere, except a slightly hardened spot over the ascending colon, whenever deep pressure was made. The position and size of the liver were normal. Her general appearance was cachectic, the colour of her skin being of a yellowish hue.

In the beginning of March, she began to suffer from dyspnœa, occurring at first only during the night. As both percussion and auscultation showed the lungs to be in perfect order, I supposed the dyspnœa to be the result of nervous asthma, and prescribed morphine in the usual dose. Within a few weeks, however, emphysema pulmonum was rapidly developed, the dyspnœa increased, and finally the patient was unable to get any sleep, or even to remain in the recumbent position. I now ordered the inhalation of the oxygen, expecting of course, only to alleviate the urgent dyspnœa, and to render the patient more comfortable. In this I succeeded admirably. The inhalation of three gallons of the gas relieved the patient greatly, allowing her also to sleep during the greater part of the night, which had not happened before for over a week.

The patient died from exhaustion, April 19th, 1870. I was not permitted to make an autopsy.

NOTICES TO CORRESPONDENTS.

ON VACCINATION.

To the Editor of the "Medical Press and Circular."

DEAR SIR,—Will you kindly give a few words in review of the enclosed "Handbill on Vaccination," and very much oblige,—

Dear Sir, your obedient servant,

Worcester, July 5th, 1870. WILLIAM W OODWARD, M.D.

Extract:—"*The statistics of all countries distinctly prove* that the deaths, loss of sight, and disfigurement from small-pox diminish in proportion to the practice of vaccination. Before vaccination was discovered, small-pox caused *half a million deaths* in Europe annually, of which *eighty thousand* occurred in Great Britain and Ireland; while a considerably still greater number lost their sight and were disfigured for life from the same cause. Now wherever vaccination is stringently enforced, small-pox is unknown. It has disappeared from Ireland, where vaccination is universal, almost entirely from Scotland, where 90 per cent. of the population are vaccinated, and the disease is only lurking in England in places where it has been imported, or where vaccination has been neglected. The fact that the nurses at the Small-Pox Hospi-

tal (who are all regularly re-vaccinated) have never taken small-pox, is asufficient proof of the power of vaccination over that disease."

⁂ It gives us very great pleasure to notice some of the arguments contained in Dr. Woodward's "Handbill of Vaccination." The deplorable ignorance of Professor Newman and other well-meaning gentlemen on most matters connected with pathology, have rendered them bitter opponents of the Compulsory Vaccination Acts. Happily, the nation at large is not of the opinion of these gentlemen, or we should have the mortality of Paris from small-pox 250 a week, re-enacted in London before long. If Mr. Newman and his friends in the "Co-operator" would but look at the admirable little work of Dr. Guy on hygiene, recently published in the form of "Lectures on Public Health,' they would, we feel almost persuaded, be inclined to abandon their crusade against the greatest medical discovery ever made,—that of vaccination as a prevention of small-pox.—Ed. M. P. & C.

ENTIRE LOSS OF SPEECH.

To the Editor of "The Medical Press and Circular."

Sir,—Under the above head Dr. Waring-Curran has described an interesting case which occurred in his practice.

To show the entire loss of the faculty, I quote that gentleman's words:—"No human sound of any kind can escape her; she is more mute than the most dumb patient I have ever seen." Farther on in his paper are these words:—"The case demonstrates, however simple a disease typhoid fever may appear to be, how disastrous it may prove itself by causing afflictions like the present, *which no art can modify, nor method of treatment remedy.*"

To this harsh opinion I cannot but take exception, and I am sure that Dr. Waring-Curran will agree with me that there is reason for my so doing, since it *is* in the power of art to modify such a defect as he describes, and of treatment to remedy such a loss.

"There is no paralysis, no symptom of cerebral mischief, no wasting of any of the muscles, nothing unusual *to be observed* about the throat or tongue; there is perfect power in all the limbs." If there be "no cerebral mischief," it occurs to me that the cause of the aphonia lies in paralysis of the vocal cords (in which, of course, there would appear to be "no paralysis, no symptom of cerebral mischief, &c., &c."): and then the treatment by external galvanism to the throat and neck, and by internal galvanism to the vocal cords themselves by means of Dr. Morell Mackenzie's instruments, would, with the aid of the administration of strychnine, restore the voice and the power of speech. I have had not a few cases similar to that described by Dr. Waring-Curran, with the exception that the utter inability to make any sound in the throat did not follow typhoid fever, and I am able to say that the power of making a sound, and the faculty of speech, were restored by the means I advocate. It was only yesterday the following case came under my notice:—

J. T. presented herself some time since at the out-patients' department of the Hospital for Women and Children, complaining of total loss of speech, and of the power of forming any sound in the throat. This had been going on for some time before she had applied to me for relief. She was put on strychnine and ammonia, and galvanised morning and evening, the poles of the battery being opposed externally. The power to form sound, and to fashion the lips, &c., so as to frame words, was brought back in a few days, and soon the faculty of speech followed. Considering herself cured, she discharged herself, but had shortly afterwards to apply again. The same benefit from treatment resulted, but as the voice did not permanently remain, I asked Dr. Morell Mackenzie kindly to admit her into the Hospital for Diseases of the Throat, which he at once did. Yesterday she came to me speaking as well as ever. It will, however, need a little time to test whether temporary or permanent relief has been afforded.

By means of galvanism and suitable internal treatment, I have been enabled to restore sight, where that sense was even wholly lost; to make the deaf to hear, as well as the blind to see and the dumb to speak, and the halt and the lame to walk aright.

In reading over Dr. Waring-Curran's article a second time, I notice he says, "Everything has been done that science and art could suggest to restore the voice;" but if he has not tried the plan I have advised, I should commend it as worthy of a fair trial.

G. de Gorrequer Griffith, L.R.C.P., Lond.,
Senior Medical Officer to the Hospital for Women and Children.

VENTNOR COTTAGE HOSPITAL AND ITS CERTIFICATES.

To the Editor of "The Medical Press and Circular."

Sir,—I quite agree with your article on the letter of your correspondent last week, as to the abuse you have so properly denounced.

I, too, have been asked to fill up these lengthy forms. I have always objected to fill them up, but have done so out of a feeling of charity, as the poor patients would otherwise be refused.

I believe, however, that in the case of the vaunted Ventnor concern, the majority of applications are refused.

Alpha.

Obscene Advertisements.—We, who have done no little in the field of endeavouring to purify the columns of the daily press, delight to find that our able contemporary, the *Saturday Review* has gone to work with a will for the past few weeks in exposing some of the contumely connected with indecent advertisements, whilst there is recommended a system for disinfecting the journals such as that long since advocated by our correspondent, "Justitia," in these columns, and endorsed by ourselves. We are glad to find that our own remarks, combined with those of the *Saturday Review*, have purified the columns of the *Standard*, *Daily Telegraph*, and *Observer*. We regret, however, to find the *Morning Advertiser* so stupid and blind, ultimately, to its own interests, for unless a radical and sweeping change is effected in refusing the insertions of the quacks' advertisements, we must ask our professional readers not to subscribe to the paper. We agree with the *Saturday Review* that the *Standard* should not admit even in the hour of penitence and purification, such advertisements as speak of ladies for *corps de ballet*, "who must be well formed, and of good personal appearance," &c. Papers admitting such advertisements we must not allow our daughters or sisters to peruse. "To the pure," of course, "all things are pure;" but the corruption and vileness of *Reynolds's* and *Lloyd's* are too much for a refined mind to bear. We submit the Manchester papers—the *Manchester Courier* and the *Manchester Examiner*—together with the provincial press of England, need also a thorough cleansing, and we agree with the general tenor of the remarks made by the *Saturday Review*, of July 9th, that if such journals cannot be reasoned into decency and propriety they can be *starved* into it. We ask all fathers and heads of families to look to the morning papers, and admit no organ which represents the charlatan, stoops to immorality, and trades upon indecency.

M.D. (Calcutta) informs us that the question of over-population and large families is exerting great interest in India, where "many parents are so poor, that they foresee their children must be paupers." He will scarcely expect us to reply categorically to his questions.

Dr. Henry Murray.—Your letter has been forwarded to the secretary, who will doubtless reply to your inquiries.

How not to do it.—A correspondent of the *Times*—"Sperans"—writes to the effect that a few years ago he bequeathed a few thousand pounds to produce quite £200 per annum to St. George's Hospital; but, finding from a newspaper report that a retiring official of the institution was asked to accept a pension of £200 a year, "Sperans" changed his mind, and altered his will. We venture to inform "Sperans," had he consulted the Governors of St. George's Hospital, the newspaper report which produced so serious an injury to the hospital fund could have been satisfactorily explained.

VACANCIES.

Charing-Cross Hospital—Assistant-Surgeon.
Hospital for Women, Soho square—Surgeon.
Birmingham Lunatic Asylum—Assistant Medical Officer. Salary, £80.
Preston Royal Infirmary—Junior House-Surgeon. Salary, £60.
Worcester Infirmary—Assistant House-Surgeon. Salary, £50.
St. Mary's Hospital, Manchester—Two Out-door Medical Officers. Salaries, £60.
Lincoln Dispensary—House-Surgeon. Salary, £120.
Lancaster Union—Medical Officer. Salary and extras about £70.
Liverpool Royal Infirmary—Demonstrator of Anatomy.
Anderson's University—Professorship of Scientific Chemistry.
University of Durham—Medical Tutor. Salary, £120.
Middlesex Hospital—Physician's Assistant.
Berkshire Hospital—House-Surgeon. Salary to commence at £60.
Newport Union, Monmouthshire—Medical Officer for each of five districte of, the Union. Salaries, £30, £40, £40, £40 and £45, respectively.
Leeds Dispensary—Assistant Resident Medical Officer. Salary, £60.
Ashton-under-Line Infirmary—House-Surgeon. Salary £80, with board and residence.

APPOINTMENTS.

Alexander, R. R., M.B., Assistant Medical Officer at the Buckinghamshire Lunatic Asylum, Stone.
Bennett, J. H., M.D., Medical Officer to the Redcar Board of Health.
Derry, B. G., M.R.C.S., Assistant Medical Officer at the Cornwall Lunatic Asylum, Bodmin.
Dickinson, E. H., M.B., House-Physician to St. George's Hospital.
Harrison, A. R., M.D., Resident Medical Superintendent of the General Lunatic Asylum, Douglas, Isle of Man.
Haward, J.W., L.R.C.P.L., F.R.C.S., Assistant-Surgeon to the Hospital for Sick Children, Great Ormond street.
Holroyd, W. S., M.R.C S., House-Surgeon to St. George's Hospital.
Jessop, T. R., F.R C.S., a Surgeon to the General Infirmary, Leeds.
Keyth, W., M.D., Consulting-Surgeon Royal Infirmary, Aberdeen.
Mitchell, H., M.B., Medical Officer for the Cockermouth District No. 2 of the Cockermouth Union, Cumberland.
Nunneley, F. B., M.D., additional Assistant-Physician to the Hospital for Sick Children, Great Ormond street.
O'Connor, J., M.D., Medical Attendant to the Constabulary, Ardfert.
Rayner, Dr, Assistant Medical Officer at the Bethlehem Hospital for Lunatic
Rutherford, J., M.D., Medical Superintendent of the Argyll and Bute Lunatic Asylum at Lochgilphead.
Shaw, T. C., M.D., Medical Superintendent of the Metropolitan Asylum District Asylum at Leavesden.
Thomas, J. D., M.B., F.R.C.S., Resident Medical Officer at the University College Hospital.
Thursfield, W. N., M.D., Officer of Health for Wellington, Salop.
Williams, J. F, L.S.A.L., Medical Officer and Public Vaccinator for the Eythorne District of the Eastry Union, Kent.
Wood, J., L.A.H.D., Resident Apothecary at the County Infirmary, Cashel, Co. Tipperary.

Marriage.

Stone—Hooper.—On the 11th of July, at West Lavington, Wilts, by the Rev. Matthew Wilkinson, D.D., Prebendary of Salisbury, Wm. Donnett Stone, M.D., F.R.C.S. (exam.), of 31 Myddelton square, to Emily Josephine, only daughter of William Hooper, Esq., of Littleton House, West Lavington.

EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By G. A. Gordon, M.D., C.B.,

Deputy Inspector-General of Hospitals.

(Continued.)

Cholera.—The notes upon which my present observations are based, range at intervals from 1841 to 1867. Some refer to actual personal experience, some to cases casually seen in course of inspectorial duties, while others are the result of perusing official documents, as well as the works of army surgeons who are, from their position, capable of expressing themselves with some degree of authority upon the subject. I am well aware that of late years the phenomena of cholera and the laws according to which it would appear to be regulated have been investigated with a degree of care and by the aid of scientific appliances unattainable at the time to which my earlier observations refer; yet, how far knowledge in regard to these two important points has been advanced beyond the point at which it then stood is a question, the solution of which must, I fear, be left to individual thinkers.

With these preliminary remarks I would observe that, like all other medical officers who have been some years in India, two forms of the disease have come under my notice, namely, the asphyxiated and the spasmodic. The former is of comparatively unfrequent occurrence, but its attack is, in the great majority of instances, fatal; the latter is the form which usually prevails epidemically, and although it also is unfortunately fatal in a ratio almost beyond any other disease which now affects our troops in India, it nevertheless leaves room for treatment, and affords recoveries in so many cases, even of the most desperate nature, as to encourage us in continuing our remedies when their use is based upon scientific principles. These two forms are not recorded separately in statistics of regiments, so that it is practicable to state the actual ratio in which they respectively occur, neither am I now in a position to represent in figures the precise extent of, and mortality among, the various classes of persons borne upon a regimental establishment. In the records of the 10th Foot, however, I find accounts of 162 cases as treated from time to time. Of these, 85 were fatal among the soldiers, giving a ratio of mortality of 52·46 per cent.; of three officers attacked, all died; of 24 women 17 succumbed, or 76·83 per cent.; and of 10 children attacked, 8 died, or a ratio of 80 per cent. In some of these instances the disease attacked isolated individuals, but in the great majority it prevailed in epidemic form, and when it did so its rate of mortality was greater than under the former circumstance.*

The records of the regiment clearly show that the disease prevailed most extensively and severely during the first four years of its Indian service. The actual cases of the malady are stated to have been on an average 120 per annum during that period, the average yearly number for the subsequent nine years being 43. These facts are quite in accord with what has been noted by other observers, for it is now acknowledged that although the danger is undoubtedly great of cholera appearing in a regiment during the earlier period of its Indian service, yet epidemics of this disease often occur in what used to be called *seasoned* corps as well as individuals; that in the case of persons their greatest liability to such attack is first in the early period of their residence in the country, and again when they have spent many years in its exhausting and *malarious* climate.

As to the precise nature of cholera, or of the influence upon which the disease primarily depends, it may, I think, be confidently asserted that, notwithstanding all the care and scientific acquirements of the able men who have set themselves to the investigation of this point, our actual stock of definite knowledge regarding it is little if at all more satisfactory than it was many years ago. True it is that we may be upon the threshold of discovery, yet the

* See also a paper on this disease by the present writer, *Med. Times and Gazette*, Nov. 22, 1856.

condition as at present existing is as I have stated, and I much mistake if some of the remarks on the disease published in 1846* are not quite as applicable now in 1870 as they were when first written. At that time I had witnessed two outbreaks of the disease in India, namely, one in the Buffs in 1843, while the regiment occupied the fort of Allahabad, and again the following year on the return of the corps to that station after the campaign against Gwalior. I then observed that were the question asked What is cholera? nine-tenths of the Profession would answer, and correctly, "I do not know." "All we do know is, that the disease is generally attended by profuse vomiting and purging of a clear liquid resembling rice water; and from the immense quantities evacuated we can only account for its generation by supposing it to be the serum of the blood, of which there is hæmorrhage going on from the inner surface of the stomach and bowels." Can it yet be asserted that, as regards true knowledge of this subject, we are in a better position than we then were? Nor is it in regard to cholera alone that a similar remark is applicable. In the great majority of *morbid* conditions, and in the ordinary manifestations of the *vital* functions, we are accustomed to observe definite processes as taking place, but when we endeavour to trace them back to their ultimate causes we speedily find ourselves dealing with mere abstractions. This fact must be familiar to all who have endeavoured to trace up the causation of disease to its primary source, and, therefore, I need now only remark that we are probably neither in a worse nor better position in regard to our theories as to the origin of cholera than we are of many other diseases which we are accustomed to speak of as depending upon *malaria*, climatorial influences, epidemic influences, septic conditions, and so on. What really are all such terms but mere abstract expressions?

An attempt has indeed been made to define the actual influence upon which the disease cholera depends, but it is almost needless to observe the definition has merely resolved itself into words; the actual conditions have not been demonstrated. Thus we read in one place the actual cause described as consisting of an unknown something the essentials for the development of which include 1. The cholera miasm; 2. Humidity, and 3. The prevailing wind; that it is earth born and air conveyed; again, that the cholera germs lie hidden in the ground, that occasionally they are extricated in sufficient quantity to develope a few cases of the disease, and that when the atmospheric condition, including air and water, is favourable to the *cholera seed*, the disease becomes developed in its full vitality. These are indeed not the actual words employed by some modern writers on the subject, but they indicate the purport of speculations intended to take the place of established facts.

It is true that of late years various circumstances have been observed which would seem to indicate that an alliance of no distant kind exists between cholera and certain forms of fever. In reports of medical officers stationed at Peshawur, I, on many occasions between 1862 and 1867, observed remarks to the effect that such apparent alliance between cholera and intermittent fever had been suspected by them; that, in fact, in many instances, it was not possible in the very early stages of the attack to prognosticate whether the symptoms were those of cholera or of the severe form of ague prevalent in that insalubrious valley; at Calcutta I have had occasion to observe a similar circumstance, and statistics prove that epidemics of cholera are in many instances followed by epidemics of fever. Medical officers who have served in the West Indies as well as in India, have, moreover, remarked that in not a few cases the character of the disease reminds them much of what they had observed in yellow fever. I have myself seen two cases in which this was particularly apparent, namely, one that of an officer in Calcutta, and a second in the person of a soldier at Tientsin in China. In both, *black* vomit was unequivocally present, and in both the attack was rapidly fatal. May I also refer to my papers on "Army Surgeons," * in the *Medical Mirror* for 1868-69, for further evidence as to the supposed relationship of these two terrible forms of disease? These circumstances may no doubt indicate the fact, so often expressed by army surgeons, that geographical position and conditions connected with physical geography, climate, &c., modify the phenomena produced by similar causes, but they do not enable us to arrive at any more definite views than we already entertained as to the ultimate nature of that cause.

Adverting to the manner in which the disease makes its attack and is propagated, the experience of our army medical officers is very much in accord. They know that the disease may and does prevail, not only in different parts of India, but in the same stations at different periods of the year, and that in the great majority of instances the outbreak of an epidemic is preceded by a marked prevalence among the soldiers of diarrhœa, although there are exceptions to this rule. The results obtained from a study of the records of the 10th Foot are quite in accord with general experience that the disease usually begins in Bengal during the earlier part of the year, and gradually travels from that point towards the north-west. They moreover indicate that the course of the epidemic is not under all circumstances thus regular. For example, in 1845, when cholera occurred and prevailed fatally in that corps and the 9th Lancers at Meerut in 1845, the epidemic without doubt reached that station from the westward. In confirmation of the view that the disease does not in all cases occur in the North-west Provinces as an extension of the disease from Lower Bengal, I would refer to what Dr. Macpherson † says on this subject. He believes the common notion to this effect to be groundless, and the importance in regard to the disease attached to the Gangetic valley to be quite exaggerated. Among other facts he mentions the occurrence of the disease among the pilgrims of Hurdwar in 1783 without any recorded connection with Bengal; that similarly in 1816, it occurred to all appearance, spontaneously among a tribe of gipsies halting at Sahibgunge; that in 1781 it was introduced into Bengal, having probably come down the Gangetic valley.

On more recent occasions its progress has been found to be irregular; the epidemic not only missing places in its onward progress, but actually doubling back upon itself as it were, and devastating those very stations or villages which it had at first spared. In other instances it has been found to spread in all directions from a place or a body of persons affected, as if from so many distinct foci, while in still another set of cases it has suddenly appeared at several places at great distances apart, the intervening towns and districts remaining free and throughout the season completely exempt from it.

Among other characteristics of the disease I may observe that outbreaks seem to have no reference to the prevalence of particular winds or "monsoons;" that cases do not occur continuously in barracks, houses in cantonment, or even in towns and districts; and that although in the great majority of instances communication can be traced between the affected and persons or places subject to the disease, yet it is not always possible to establish any such connection. It is impossible to do so in what are called sporadic cases of the disease, and often in the case of ships in which it suddenly appears many days after being at sea.

Unquestionably, the malady in many instances seems to become localised in the most filthy part of cantonments and cities. This is not always the case, however, as illustrated during the attack among the Buffs at Allahabad, for at the very time the men of the 3rd Foot were severely visited by it, notwithstanding their being carefully managed as regards cleanliness and accommodation in barracks, the

* Principal Diseases of India. Published by Trelawny Saunders.

* Published separately by Lewis of Gower street.

† Cholera in the East.

native inhabitants of the neighbouring dirty and crowded baazar were comparatively exempt.

A point of considerable importance in reference to the history of this disease is the fact that although the occurrence of accidental or sporadic cases is, in many instances, preliminary to an outbreak of the malady in epidemic form, yet they are not necessarily so ; while, on the other hand, an epidemic may suddenly burst upon a station or body of troops without the occurrence of any conditions to account for the circumstance. The most delicate chemical experiments have hitherto failed to detect any difference in the condition of the atmosphere on such occasions as compared with times when the disease is altogether absent, and the supposed prevalence of *fungi*, *blue mist*, and various other apocryphal existences must as yet be looked upon as constituting more a plausible and convenient theory than as established facts. We do know, however, that whether an epidemic attacks suddenly and unexpectedly, or advances steadily from more distant stations, whether preceded by diarrhœa or not, its greatest mortality takes place for the most part in its earliest period. It may disappear as suddenly as it occurred, or, according to a common expression, gradually expend itself ; it may continue onwards in a definite course, may as it were retrace its path as already mentioned, or seem to altogether disappear, either for that particular season or for several weeks. It has generally been considered that the occurrence of a thunderstorm such as are frequent in India conduces to the termination of an epidemic of this nature. No doubt such is the case in many instances, but that the rule is by no means invariable was proved on the occasion of the outbreak already mentioned as having taken place at Meerut in 1845. On that occasion the disease seemed to burst upon the station immediately after the occurrence of such a storm, and with this peculiarity, that its early violence fell more severely upon the officers and their families, than upon the soldiers and theirs. The commanding officer and the wife of the surgeon were among its earliest victims.

At the time to which my remarks chiefly refer, the number of stations occupied by British troops in India was far fewer than they have more recently been. The greater number of them were erected either on the banks of or adjoining the larger rivers, and then it was observed that this disease seemed also to travel along the course of those streams, although, perhaps, more frequently upwards than according to the current of them. It was, however, well known that the onward progress of an epidemic was interrupted by the occurrence of a river in its track, and that certain parts of a river's course seemed never to be free from the presence of this disease. Several years have now elapsed since it was customary to send our soldiers in country boats by river to the more inland stations, or down to Calcutta from them. Steamers with the large troop boats attached to them superseded the miserable boats in which soldiers were formerly transported, and steamers have now in their turn been surpassed by the railway. During the many years, however, that troops were conveyed in the manner first mentioned, medical officers in charge of them knew well that danger always existed. When the fleet had to "come to" for the night upon a low-lying shore several cases of cholera might, as a matter of course, be looked for, while there were particular tracts along the river course, in traversing which a more or less severe outbreak was tolerably certain to occur ; yet in neither case did any circumstance present itself materially different from the ordinary conditions of the voyage. One well-known tract of this kind existed during several miles of the river course between Bhaugulpore and Monghyr. There the Ganges, which during the dry period of the year was scarcely a mile in breadth, became so large during the rains as to extend to a breadth of ten or even upwards. The district being not only very flat, but the soil of rich alluvium, tracts which, during the rainy season were completely submerged, were left uncovered during the dry seasons, and thus became prolific sources of emanations from organic matters deposited in and upon them ; but then again the same remark applies with more or less force to other portions, of the Gangetic valley, and hence, I fear are not here of themselves sufficient to account for the disease having domiciled itself at the places mentioned.

But there are certain localities distant from rivers where cholera is similarly domiciled—but such I am able to speak of from my own knowledge. It occurs at Raneegunge and from thence some distance along the grand trunk road, or, in other words, in the coal district there ; and there are probably readers of these pages who, when marching with troops by the road in question, have had painful experience of the circumstance. When a very few years ago the 55th Regiment landed in India, detachments as they disembarked, were sent by the road in question *en route* to Hazarabagh, and while on the march suffered very severely from an outbreak of the disease which occured as each in succession arrived at Raneegunge, and clung to them during their earlier marches.

It has generally been considered, and I belive with good reason, that this disease is most prone to attack persons residing upon or near ground floors of houses in India. There may, however, be exceptions to this, the epidemic appearing under certain conditions to leap, as it were, over a wall, attacking the occupants of the upper story to the comparative safety of those below. Of this an illustration occurred in my own experience very lately. When in 1863 cholera prevailed at the military station of Benares, a building formerly used as a mint was by the Rajah of that place given over for occupation by a portion of the 20th Regiment, so as to reduce the numbers in barracks. This building consisted of two stories ; an enclosure around it was bounded by a high wall, so as to cut it off from the adjoining native bazaar. The disease seemed to advance through the bazaar, and in its progress reached the building in question. Instead, however, of the men accommodated in the ground floor being the first attacked, those in the upper storey were so. In fact, I am under the impression that the latter altogether escaped, although upon this point I cannot now speak positively.

It almost amounts to a platitude to remark that among the circumstances which, under certain conditions, give rise to cholera, and localise the disease in particular places, defective conservancy arrangements and impure water are among the most constant and most important. The facts have come to be universally acknowledged ; yet, according to practical experience in India, it is found that neither does cholera necessarily prevail with greatest intensity in the dirtiest parts of towns, nor is the disease at all times caused by the use of water holding decomposing organic matter in suspension. If we are to look upon the ultimate cause of the malady as an actually existing entity, dormant under certain conditions, but capable of being roused into activity under certain as yet undefined influences, we may in some measure be able to account for the first circumstance alluded to, and explain why, for example, the parts of Calcutta, and other native towns, in which filth of all kinds is permitted to lie festering in the streets, are less constantly the scenes of cholera than streets in which, by means of so-called "drains," matters of that description are allowed to remain stagnant at an inconsiderable depth from its surface, polluting the soil and producing emanations which become doubly pernicious by the obstruction thus placed against their free escape. In the one case, such emanations are no sooner formed than they are diluted and carried away by the winds, or by the rain, whereas, in the other, they probably undergo processes which increase their injurious properties ; thus it may be that persons residing immediately over or near an imperfectly constructed underground sewer become attacked by cholera, while those in the vicinity of more openly objectionable places escape. In the same way, a ready explanation presents itself of the little injury to health which occurred from the most offensive native habit, in the absence of public latrines, or other receptacles of filth, the residents of villages, and also of considerable towns, repairing to the outskirts in the early morning to perform their functions ; so also may we ac-

count for the absence of injurious results in China, from the custom adopted in that country of irrigating the growing crops with liquid ordure, while the presence of imperfect drains or soil otherwise saturated with animal matters, are frequently visited by outbreaks of this disease. In fact, it appears to me that in many cases the system of superficial drains for cantonments in India is for these reasons more suited to the conditions of the country than that of underground sewers, such as are being now recommended for adoption.

(To be continued.)

THE DIETETIC VALUE OF ALCOHOL.*

By George Ogilvie, M.D.

Professor of the Institutes of Medicine, University of Aberdeen.

By alcoholic beverages I understand such as will yield alcohol by distillation, contain the principle either free, or in some state of combination analogous, perhaps, to what are termed by chemists ethereal compounds. The action of alcohol, and in so far therefore of the drinks which contain it, though in some of its phases sufficiently well known, is in its whole extent so complex that it has never been thoroughly analyzed, so as to indicate the functions and organs primarily affected, the precise nature of the changes induced, and the way in which they are associated so as to produce the general effect. To give precision to our ideas of its so-called exciting and depressing influence, and to show how far its action is general, and how far in the first place local on the tissues, in consequence of its constricting influence on animal matter and its great power of permeation, all this requires more careful research than has yet been brought to bear upon it. We have here, too, this additional source of perplexity, that the use of these beverages enters so largely into our convivial pleasures that to many the idea is intolerable of any objection which would, to a great extent, curtail their employment, while on the other hand the amount of evil—social, moral, and physical—which undoubtedly results from their actual abuse, has naturally excited in the minds of many such a feeling of aversion, as to put them out of a position to give a fair hearing to any arguments for their use being ever advisable or even legitimate. *In what way* alcohol exerts its influence on the system we have as yet no very clear idea. The notion formerly prevalent that it is wholly or mostly excreted again in a free state is not borne out by the latest and most accurate observations (those of Thudichum, Dupre, and Anstie), except when taken in quantity ; and then probably only in part—the portion so discharged passing off, it would seem, by the physical law of exosmose, and that part only which is retained, and altered in the system, influencing it physiologically. That a portion is discharged free is indicated by the odour of the breath and urine, but, from the affinity of the alcohol for the blood and tissues, the elimination seems to take place much more slowly than the absorption. But though we know nothing *positive* of the reactions of what is retained in the system, we may conclude that it does not undergo oxidation to any great extent—as assumed by some authors—for when any quantity is taken in a state of health the elimination of carbonic acid is reduced instead of being increased, as is also the resulting evolution of heat.

The effect of alcohol on the system is remarkably different when taken in small and in large quantities, as is forcibly pointed out by Dr. Anstie. In the former case it seems to invigorate the natural functions under depression, somewhat as food does, and therefore may be considered—when judiciously employed—a legitimate constituent of diet ; while in the latter, poisonous symptoms of a narcotic kind are produced, especially depression of nervous force, and, through this, derangement of most of the important functions of life. The invigorating effects, however, which are the sole result of small doses, appear also as the primary symptoms which follow the administration of larger quantities ; for this simple reason, that as, under ordinary circumstances, the absorption of the alcohol is gradual, there will generally ensue, even after an excessive dose has been taken, a stage in the series of phenomena when, the quantity in the circulation being but small, only the primary stimulating action is manifested, though as more is taken up by the vessels the symptoms of true intoxication speedily supervene. However noxious these last may be it is therefore no paradox to maintain that the preceding state may be not only pleasurable, but one also of a perfectly normal and healthy character, as mere exaltation of the natural play of the functions, and that, if the quantity taken had been sufficiently small, this state had never passed into the other.

But intoxication in the physiological sense is a very different thing from that style of it which attracts general notice, and to which the term is popularly confined. The first symptom, according to Dr. Anstie, is a flushing of the fæces (from paralysis of the *vaso motor nerves ?*) To this succeeds an impairment of the cerebral functions, and especially of the controlling power, though, as the cerebral circulation is at first quickened, the immediate result is increased rapidity of thought, to the flow of which we have to abandon ourselves from the enfeeblement of the power of control. It is probably this subsided play of cerebral action—of which a man remains conscious after losing the power of control—that is credited as an increase of the imaginative faculty.

As a farther stage the power of articulation is affected, and the co-ordination of the movements of manipulation and locomotion, and the narcotism may be pushed so far as to cause death by arrest of respiration. The first effect on the circulation is acceleration of the pulse with diminution of force, then irregularity and intermittency, and at last, in case of an excessive dose, stoppage of the heart's action. This is probably the last function to succumb ; according to Dr. Richardson the heart still continues to contract feebly when the breathing has ceased, and all outward indications of motion are over.

Side by side with the very different effects of large and small doses of alcohol, must be put this other law which greatly modifies the former—namely, that the intoxicating or narcotic effects are much more readily induced in a well-fed and plethoric state of body, than when the nutritive functions are depressed, as by exhaustion, starvation, hæmorrhage, nervous shocks, or fevers, and other debilitating diseases. Under such circumstances an amount, which would produce marked intoxication in a full and healthy state of the system, may do no more than give a stimulus to the vital processes which is wholly beneficial and followed by no perceptible prostration or other unpleasant reaction.

But, admitting that alcohol in small doses may have no prejudicial effect on the system, experience seems to have satisfactorily shown that none of the beverages which contain it are really *necessary* articles of diet, in health and under ordinary circumstances, even in the restricted sense of rendering it more perfectly adapted for the support of the fabric, inasmuch as we find not only individuals, but large bodies of men, enjoying the most robust health without using them at all. There is no reason for considering their habitual use to have any power of enabling the system, if otherwise well nourished, to bear up better against fatigue and exposure, or of neutralizing the effect of malarious influences ; and there is great unanimity on the part of those who have had most practical experience, in the opinion that their use, so far from fortifying the system against extremes of temperature, diminishes the power of endurance in the case both of heat and cold.

On the other hand there is no sufficient evidence to show that their moderate use is *necessarily* unfavourable to health or inconsistent with longevity ; so that if any choose to employ them, either as a luxury or as suited to

* Read before the Medico-Chirurgical Society of Aberdeen, June 2, 1870.

specialities of their condition, I do not see that, either on grounds of medical experience or of physiological induction, any serious objection can be raised to their doing so, keeping always within the strict limits of moderation. But here, of course, lies the practical difficulty, especially in regard to the stronger forms of spirituous liquors, of which a much smaller quantity than is commonly supposed will, in a state of health, induce a condition which physiologically is certainly one of incipient intoxication, though not generally recognized as more than healthy excitement; and experience shows that the habitual use, even in such so-called moderation, of the stronger alcoholic drinks, has a tendency to induce structural changes in the heart, stomach, and liver, which eventually give rise to various morbid affections. By its great power of permeation the spirit is readily brought in contact with all the tissues of the body, and, besides the immediate functional effects thereby developed in the nervous system, it seems also to exert a slow condensing action on the connective tissue—much as it does indeed on all animal matter—which is probably in some way concerned in those morbid indurations of the more important viscera, of such common occurrence in hard drinkers.

Seeing, then, that the use of these beverages—especially the stronger kinds—may be considered in general only a luxury, and one too grossly abused by many to the destruction of their health and peace of mind, and to the production of much social mischief, we cannot wonder that there are some who absolutely condemn their use, and that others who do not go this length would allow it only exceptionally, considering them better excluded from the ordinary diet of health. To this some writers of high professional and scientific standing have given more or less the weight of their authority. I may mention in particular Dr. Carpenter and Dr. Parkes. The latter, in his "Military Hygiène," urges very forcibly the propriety of excluding spirits and the stronger wines from the ordinary diet of health, insisting especially on the mischief of the promiscuous issue of spirit rations to troops and sailors, and referring to the experience of the American navy and of many "temperance" merchant ships, in support of the expediency of withholding these articles. Yet, granting this to be true of ordinary diet, the exceptional cases are by far too important to be safely overlooked, and the following may be mentioned as instances in which the limited and *discriminative* use of alcoholic drinks might be advantageously adopted :—

1. Under circumstances tending to induce mental depression, and thereby a predisposition to infectious or other disease, or unfitness for hearty work. The evidence, indeed, of any positive protecting influence on the part of such beverages against infectious or malarious diseases is (to say the least) not convincing, but still they seem likely to be of use—not certainly when given promiscuously to all—but administered with discrimination to those most liable to be affected with that extreme depression of spirits, which in some outbreaks of cholera appears to have a powerful effect in predisposing to the disease, and enfeebling the powers of resistance. Their use, of course, should be combined with every other possible arrangement for producing a healthy exhilaration, diverting the thoughts and relieving the despondency so liable to prevail in the presence of an excessive mortality.

2. After severe fatigue or exposure such stimulants are useful where there is any flagging of the heart's action, or much impairment of the digestive powers, for in such cases the natural restoratives—repose and food—are not always available over fatigue, sometimes produce a state of nervous agitation unfavourable to rest, but in which sleep is often readily induced by a small dose of alcohol—while in those cases in which the powers of the stomach are so easily upset by fatigue, grief, or anxiety, that food is not digested and becomes only a source of discomfort, the simultaneous administration of a modicum of wine or spirits often restores the function of digestion sufficiently to enable the system to recruit itself in the natural way by the absorption of aliment.

3. That such stimuli have any sustentative power against fatigue is neither proved nor even rendered probable by any evidence before us, but certainly, when unusual exertion becomes necessary in an emergency, the system may be thus temporarily braced up for the push; and it does not appear that the subsequent prostration is thereby increased. This applies both to bodily and mental work. Dr. Carpenter bears full testimony to their wonderful efficacy in quickening and freshening the mental power during a brief period, through which it could not otherwise have been sustained. Of course a corresponding depression is subsequently felt, but it is rather traceable to the fatigue of over-exertion, than to the reaction consequent on over-excitement. (*On Alcoholic Liquors*, p. 212.) The depression indeed is probably less than if the system had been braced up to the extraordinary exertion merely by a vigorous strain of the will or some other simply coercive influence; for the alcohol seems to be more than the mere "spur" to which Dr. Carpenter compares it—there is reason to believe that it actually supplies in some degree the unusual waste of special tissues in the conditions of the case. Of course the health suffers under the habitual recourse to stimuli in such circumstances, but the damage follows rather from the repeated overstraining of the powers than from any immediate bad result of their use if pushed only so far as to meet the necessities of the case.

4. Alcoholic liquors may also be of use in helping through a temporary exposure to cold, when the natural resource of increased muscular exertion is not available. But there is a singular unanimity—both among physiologists and men of practical experience—that their habitual use greatly impairs instead of increasing the power of enduring repeated or long-continued exposure to cold, besides rendering such exposure more liable to be followed by injurious consequences to the health.

5. Alcohol has been recommended as of use when the diet is insufficient, from its apparent power of diminishing the metamorphosis of tissue and the resulting waste by excretion. This it has in common with tea, coffee, tobacco, and quinine, but probably in a greater degree. But as such husbandry of food at the rate of change in the body must diminish the *energy* of the vital processes, it can only be considered as the lesser of two evils—it may enable men to subsist longer on a limited supply of food, and prevent some of the sufferings of starvation; but it must be attended with a loss of strength and a depression of health, rendering them more liable to succumb under the pressure of disease or other causes of exhaustion.

In all cases the substantive power of alcohol is much more marked in those who are in a state of exhaustion or depression, than in a fresh and well-fed condition of the nervous system, and its beneficial effect is shown only when the quantity given is such as not to induce any of the proper symptoms of intoxication; but when the powers of life are much exhausted, and the strain or exposure is great, large doses may often be given without this effect being induced, while in a full and vigorous condition of body a comparatively small quantity will do so.

6. The most legitimate customary use of alcoholic beverages is in those cases which lie, as it were, between health and disease, such as that of chronic dyspepsia, in those who have overtaxed their strength or otherwise injured their tone of health, in which the patients labour under a deficiency of appetite and digestive powers without indications of disordered action in any organ. In such cases, with the assistance of a small but habitual allowance of alcoholic stimulants, a long life of active exertion may be sustained, while the vital powers would speedily fail without their aid, for want of the measure of food which the system needs, and which no other means seems so effectual in enabling it to appropriate.*

The *modus operandi* is not so clear, but, as we know from the experiments of physiologists that the local application in moderation of alcohol to the mucous mem-

* Carpenter, Physiol. of Temperance, p. 183.

brane of the stomach increases the flow of gastric juice, we may fairly assume that its judicious administration will increase the digestive powers, in cases where their deficiency is due to an imperfect flow of the solvent fluid. The great power of permeating animal membranes characteristic of spirit may also possibly facilitate the absorption, as its stimulating properties do the reduction of aliment, for it is quite conceivable that in the process of endosmose the alcohol may carry along with it a proportion of nutrient matter. The local effects, indeed, of the application of alcohol are deserving of more attention than they have yet received. It is, I believe, in the majority of cases the best of all discutients, and has a very remarkable effect in relieving many forms of cutaneous irritation and other local inflammations; so much so, as to give some reason for concluding that the virtues of this nature ascribed to various officinal *tinctures* and *liniments* are really due to the spirit entering into their composition. Of the same nature I am inclined to think is the beneficial action of vinous and spirituous liquors in weak digestion. Here also I believe that their operation is mainly local, and that they act very much as internal embrocation to the digestive organs. It is a farther question, on which, however, time will not now allow me to enter, whether they act directly by their free and rapid endosmose on the capillaries of the past, or indirectly by a reflex action, through the *vaso motor* nerves.

The same *general* principles will apply to the corrective power of alcoholic drinks in other forms of weak health—the main object of their use being to invigorate some important function, previously depressed—as the action of the heart or the play of the nervous system—so as to restore the balance of health, and allow the other vital processes fair play. When the effect goes beyond this, it is prejudicial instead of being advantageous.

When we pass from weak health to obvious disease the instances in which alcoholic liquors may be administered with benefit are naturally more frequent, but they are of a kindred nature, falling principally under the following heads :—Debility connected with dyspepsia ; prostration from starvation ; hæmorrhage or profuse discharges ; nervous shocks, as from extensive skin burns ; and certain stages of fever. The beneficial action of alcohol in such cases is attended with phenomena strikingly different from those which it produces in the healthy body, where its effect is to lower the animal heat, while in the debilitating affections where its use is indicated it raises to the normal standard the temperature previously depressed, as is well shown, especially in cases of sinking from hæmorrhage. How is this to be explained ?

Is it by the direct oxygenation of the spirit ? I think not,—at least, in the main—for though it might be supposed *à priori* that, from the combustibility of alcohol, its presence in the circulation would raise the temperature by its direct combination with oxygen in respiration, and though some writers have thus explained its effect in keeping up the animal heat and vital force generally in the treatment of extensive burns of the skin, still we have as yet no direct evidence of an increase in the production of carbonic acid under its administration in such cases, while in a state of health its free use has been clearly shown to lower both the temperature and the amount of carbonic acid exhaled.

May it not simply be that, so long as the action is merely to invigorate the heart's play, the impulse thus given to the circulation tends of itself to raise the temperature ; but immediately on any narcotic effect being induced, the capillary circulation is so affected as to interfere with the due reaction between the blood and tissues, and thereby to diminish oxidation ; for the amount of oxygen absorbed must be in close correspondence with that of carbonic acid formed in the blood, inasmuch as the one gas is taken up by the displacing action of the other ? Now, in a state of high health and full feeding so trifling an amount of alcohol suffices to induce the preliminary stage of its intoxicating or narcotic action, that it may be reasonably questioned if we have as yet any satisfactory account of its effect on the respiration and temperature in doses too small to have any influence of the kind.* Only we know that in disease, quite as much as in cases where it may be used in health, the beneficial action of alcohol is shown so long only as it is given in quantities short of producing its characteristic intoxicating effect on the nervous system, even in its slighter degrees, though a large amount may sometimes be given in depressed states without any appearance of such symptoms.

To go more at length into these uses of alcohol would lead me into the department of therapeutics, to which it is not my object at present to make any reference, except as eking out the brief abstract, now attempted, of its dietetic value.

Hospital Reports.

ST. VINCENT'S HOSPITAL, DUBLIN.

Diffuse popliteal aneurism.—Difficulty of diagnosis.—Amputation by Wharton's mode.

By E. D. Mapother, M.D.,
Examiner in Surgery, Queen's University.

I publish the following case thus prematurely, being unwilling that it should be delayed for six weeks, till my return from an American tour.

T. G., a thin and most pale and bloodless lad, aged seventeen, sought admission to St. Vincent's Hospital on June 23rd, for "a swelling behind the knee." As he removed his trousers I remarked to the class that the swelling had much the shape of aneurism, but the history and character of the case dispelled that notion. He said that when rising from bed one morning towards the end of March he felt a small, somewhat moveable lump above the calf of the right leg, and found that the joint was slightly stiff. He had never received an injury. He poulticed the swelling, which gradually increased until his admission to hospital. The swelling equalled in bulk a large cocoa nut, reaching from the upper fourth of the calf to three inches above the flexure of the knee. As the patella moved freely, and as there was not, nor had there been, any pain or fulness in front, it appeared the joint was healthy. There was no pulsation, thrill, or bruit, in any part except at the outer condyle of the femur, where it seemed that the superior external articular artery had become increased. It struck us that the vessel was the seat of the pulsation, as it existed in a narrow line over the elastic mass. The swelling was firm and elastic, save in two points, which being soft, and projecting to the extent of about half a walnut, suggested that they contained fluid. The patient had never complained of pain. There were three of the glands near the saphenic opening enlarged, but not hardened, and for two inches along the vein there seemed to be a thickened chain of lymphatics. Several large tortuous veins were visible on the surface, which was not otherwise discoloured. The pulsation of the tibial arteries was indistinct, but there was not œdema or coldness of the limb. Extreme anæmia, with murmurs in the neck and at the cardiac orifices, and a weak pulse beating 90 in the minute, were the only constitutional features worthy of note. On the 2nd inst. an exploring needle was thrust into one of the soft points, for two inches, and on the 5th into the other ; five or six drops of reddish serum flowed along the groove in each instance. The site of the first pulsation became, after four or five days, of a dusky brown hue, and more soft and prominent than before, and continued to discharge a little serum. I and all my colleagues after repeated consultations believed the tumour to be encephaloid cancer, and in this opinion three of the most able hospital surgeons

* According to Dr. Richardson's latest experiments the *immediate* result of the administration of alcohol—answering to that of a very small dose—is to raise the temperature a degree or less. This is followed by a depression of five or six degrees, as its intoxicating action is progressively developed.—*Medical Times*, Dec. 18, 1869.

in Dublin, who had each separately examined the case with us, unhesitatingly concurred. All advised removal of the limb, one suggesting disarticulation at the hip. Another eminent surgeon, Mr. Colles, who examined the tumour, wrote to me (for I was unable to be present) :—"I incline to the opinion of aneurism, but decidedly it is a hard nut to crack." We could not adopt this great surgeon's view, having regard to the want of pulsation, bruit, thrill, diminished bulk on pressing the femoral, œdema or coldness of the limb, to the youth of the patient, his account of the case, and the result of exploration. The lad anxiously desired the operation, although informed that his weakly state promised but a slight chance of success. On the 12th inst. I amputated in the upper third, so as to saw the bone near the top of the medullary canal, and I made a single square flap from the anterior and outer aspects—the plan introduced by Mr. Wharton, Vice-president of the Royal College of Surgeons. The simplicity of this operation, and the adaptation of the flap round the bone to the inner and posterior aspects where the soft parts were cut straight down by a single sweep of the catlin, were most satisfactory. Very little blood was lost during the operation, but during the afternoon and the next morning there was considerable venous oozing due to the great poverty of his blood.

To-day (16th, when I must leave town) he progresses favourably, and I feel certain my colleagues will afford him every possible chance of success.

Dissection proved that the tumour was an aneurism, the sac of which had given way. Half-coagulated and half fluid blood lay immediately under the skin, but the unbroken part of the sac towards the joint was filled with a mass of solid fibrin as large as an orange. The gastrocnemei muscles were broken down, the posterior ligament and periosteum stripped from the tibia, and the bone indented and softened.

It is consolatory to reflect that the patient did not suffer by the erroneous diagnosis; for with this large diffused aneurism, with sloughing, suppuration of its contents, or destruction of the joint imminent, amputation was advisable, and that before he had been further reduced in strength.

When aneurisms have been mistaken for tumours and abscesses by such masters of surgery as Desault, Dupuytren, Earle, Dease, Syme, Pirogott, and Paget, it is not surprising that the mistake should recur; but, in order that diagnosis may be perfected, it is the duty of every surgeon to record such cases with accuracy and candour.

ON THE PROSPECTS OF THE SEWAGE QUESTION.

Discussion at the Metropolitan Association of Medical Officers of Health on Dr. Letheby's Paper.*

Dr. Cobbold said that individually he regarded the sewage question as one which was three parts out of four a chemical question. On this account he thought that chemists should have the advantage of speaking first upon it. Dr. Letheby had referred specially to the remarks made by him in his *brochure*. Now, though the observations he made there were written in a warm—perhaps too warm a strain, he believed there was no statement which he was not still prepared to substantiate. And he thought, since he had gained more experience in experimental researches, that he could now write a pamphlet much more cogent than that to which Dr. Letheby had alluded. With reference to parasitic diseases, he would only say that he knew of two patients in this country who were suffering from that frightful malady which was so destructive in Egypt. These patients at every urinary discharge must pass a number of the eggs of this parasite, and if the number of persons so afflicted were increased five-fold, the chances of the extension of this disease must likewise increase. But happily there were so many contingencies which the parasites had to encounter before they arrived at the human body that the community were yet spared; still he held by the statements contained in his pamphlet. Then take the case of ordinary tape-worm disorders, respecting which he had much experience. There were about 3,000 persons in London suffering from this cause, who each passed from 4 to 12 joints a day, each joint containing 30,000 mature eggs, which would give at least a daily return of 450 millions, but he believed 1,000 million eggs was nearer the mark. A certain number of grains of organic matter per gallon were found by chemists in sewage, of which organic matter these eggs must be part and parcel. A handful of large entozoa parasites had been taken from the Craigintinny meadows. If this sewage were distributed far and wide, it was certain that a considerable portion of these millions of eggs must gain access to the herbivora. It was known, from experimental researches, that measles were developed productively in beef. It was a popular notion that pork only developed measles, but he would assert that in underdone beef persons ran a greater risk. The proportion of tape-worm disease derived from measly beef was as 7 or 8 to 1 in the case of pork. It was, therefore, to incur an enormous risk to distribute sewage which contained these germs over the land. It was possible to decimate the population of any town within a certain number of months by the distribution of tape-worm germs, there being one tape-worm in particular which produced a disease of the human body at present causing the death of 400 persons annually in this country. If that parasitic disease should increase in the same proportion as other parasitic diseases, such as the ordinary tape-worm, a result would follow such as still obtained in Iceland, where one-sixth of the population died annually from this cause. Having these facts to deal with, and knowing the developmental process through which these parasites passed, he thought they were called upon to ask people to pause before adopting a scheme so gigantic as that now proposed, fraught as it was with consequences so serious as those which he believed were involved in it.

Mr. Holland said he did not believe any portion of Dr. Letheby's paper, and he thought the writer was inconsistent with himself. In the first place he alleged that twenty times its volume of water would purify the sewage poured into it, and afterwards he asserted that even a small quantity of water from irrigation meadows was poison. Was Dr. Letheby prepared to recommend that the soil should be burnt; if not, what did he propose to do with it? Unless he was prepared to recommend that all human manure should be burnt to avoid the supposed risk, his argument went for nothing. He (Mr Holland) believed that the danger of spreading disease by the irrigation system was purely imaginary. Where was the evidence of disease having been produced where the system was adopted? He had made inquiries on the subject and could find none. At Carlisle he asked whether the sheep had the rot, and was answered that they had not. At Edinburgh cows had been fed with grass from the irrigated meadows for 60 or 70 years, but there was no evidence of the prevalence of disease amongst them. It was true that they were not very healthy, but this arose from their mode of life. Everything was done to stimulate the production of milk from them, and they suffered from want of exercise and fresh air. Sewage was nothing but manure suspended in water, and the error was not in putting it on the land at all, but in putting it on in excess. At Carlisle he had been told that the residents in the neighbourhood of the irrigated fields were unhealthy, but on inquiry it turned out that there were no inhabitants in close proximity, and of those who were anywhere near there were abundant causes of unhealthiness in the condition of their houses.

Dr. Carpenter considered that the arguments of Dr. Letheby were based upon a false foundation, and that either he had little practical acquaintance with the facts from which he had drawn his inferences, or had taken only such portions of them as were calculated to sustain his view of the case. Dr. Letheby had alluded to some statements made by him, and had specially referred to the sanitary state of the fields at Beddington. The people of Croydon were some of the earliest to adopt any sanitary arrangements at all. They were compelled to adopt some plan, because of the terrors of the law—no less than five or six injunctions having been obtained against them, and the local board were threatened with committal to prison unless they ceased to do certain acts. That was in 1858, and in 1859 and 1860 they obtained powers to do what they had since continued to do. In 1860 the irrigation meadows were laid down, and they had been in active operation to the present time. Until this year no complaint, either officially or otherwise, had been made of injury arising from these meadows. Previous to 1860 the town had been put to thousands of pounds expense for damage occasioned by the sewage, but from that year till within the last nine months

* This paper has already appeared *in extenso* in the Medical Press and Circular.

they had been free from such liability. In 1860 they laid down 276 acres of land for the purpose of irrigation, and to remove the mischief which 19,000 people produced by their sewage. Since then the population of the town had increased to 50,000, and he was free to confess that the quantity of sewage was too much for the land. The result had been that occasionally of late the water was not so effectually purified as it should have been. Until 1867 no cases of fever occurred there. The water of the effluent stream passed through the grounds of a gentleman residing in the neighbourhood, and even at the present time trout might be seen swimming about in it. That being the case, was it not evident the plan adopted for dealing with the sewage was the correct plan? Indeed, Dr. Letheby said so himself, and it had been shown in that room that, if sewage were made to pass through 5 feet of earth, it would be rendered perfectly innocuous, and would be perfectly oxidized. Surely, then, the passage of sewage over land where it was exposed to the air and came in contact with growing vegetable matter, would remove from it all those elements which were injurious to health, and the water would go off perfectly pure. Dr. Letheby was in the position of an engineer who, some years ago, wrote a pamphlet to prove that it was totally impossible for a steamboat to cross the Atlantic because she could not carry sufficient coals, and whose pamphlet was issued at the very moment that a steamer was actually accomplishing the feat. The town of Croydon was a standing proof that sewage could be successfully disposed of in the way Dr. Letheby asserted to be impossible. With regard to the question of health, he might state that, since the beginning of the year, there had not been a single case of fever reported to the Board of Guardians from Beddington, and he might add, as the medical attendant of most of the wealthy families there, that he had not had a single case of fever, either typhus or typhoid, among them since the irrigation meadows commenced. With reference to the effect upon the inhabitants of Croydon proper, surely, if the emanations from the farms were so dangerous as represented, the inhabitants of the densely populated low-lying parts, which were within 500 yards of the outfall of those farms, would have suffered from typhoid. But for a long period there had not been a single case in that low district, and with the exception of a few cases of scarlet fever there had been no fever there at all. The irrigation process went on during the winter as well as the summer, and in the former period of the year the water had gone off pretty nearly free from those elements which were injurious. This was the result of experience of the system forced upon the parish of Croydon, and which they had not taken up of their own will. Having observed the process, and seen its effects, he was positively convinced that the air which passed over the fields, instead of being injurious, was a benefit to the people living around. It was a positive fact, with regard to Norwood, that the moment the irrigation fields were established the mortality fell from 18 to 15, and had remained so. Dr. Letheby said he had evidence of water coming off the fields in an impure state. He (Dr. Carpenter) knew that there had been such instances, arising from the fact that persons had gone to the fields, broken down the carriers, and pulled at the sluices, letting the water out. Dr. Letheby knew very well that the argument to be drawn from the chemical analysis of the water was valueless, unless he was aware of all the circumstances of the case.

Professor ANSTED, being referred to by the chairman, as having had experience in these matters in connexion with the city of Milan, said he hardly felt qualified to take part in the discussion, although, perhaps, so far as a certain amount of familiarity with works of this kind went, he might be able to afford some little information. The general subject appeared to him as far more belonging to the medical man than the geological engineer, if he might so denominate himself. Having had the opportunity, now and then, of noticing the results obtained during the irrigation of considerable tracts of land on a large scale, with material more or less mixed up with sewage, he thought he was justified in saying that in most cases, if not in all, those results had been certainly unfavourable to the general health of the neighbourhood. The chairman alluded to his experience at Milan. He knew the town well, and the way in which the sewage was conducted over the fields in the lower part of the town, and he believed, on the evidence of medical men—some of whom had been examined by parliamentary committees in this country, and whose evidence might be found in Blue-Books—that the result of the system pursued there was eminently unsatisfactory with regard to the health of the people living near where the works were carried on; and it was not astonishing, for no one could go into the lower parts of the town near the stream and the works without being conscious of their being eminently disagreeable, and probably unhealthy. The Italians were not particular on the subject of smells, but it was confessed that these were very objectionable. The sewage was carried over the fields, and took its course. Sometimes it was used, and in all probability, when that was the case, it passed off the ground without doing any damage to the water of the stream; but during a great part of the year such was not the fact, and the consequence was that the stream in its course was much polluted. And this was a result which he had also observed in other parts of the world. A few days previous he had the opportunity of visiting the irrigation works at Aldershot, and there it was perfectly clear to him that the farm which took the camp sewage and was working it was utterly inadequate for the quantity put upon it, and that, from the nature of the irrigation, the sewage water carried over the fields could only be used upon a very small scale, while the greater part of it necessarily ran away into the river. He could not help thinking that in most cases this must be the result. It was not for him to say, what was the right method of getting over the extraordinary difficulty which the public were called upon to face, but that some method must be adopted was evident. The question before the meeting was whether the particular method of carrying on the work suggested by the Royal Commission on the Pollution of Rivers was likely to be practically useful. As far as his own experience and knowledge were concerned, it seemed to him that the method of carrying away the sewage and utilizing it by irrigation might be successful upon a small scale, where the population was limited and the acreage was large; but he could not see much probability of its being successful upon a large scale, for what upon a small scale would practicably do no harm—say in the case of 200 or 300 acres—would be attended with very serious results in the case of a large city or town. It might be very well in the case of Croydon, where the population was small, but the limits of the adaptability of the system were soon reached, and could not be advantageously extended.

Mr. LIDDLE remarked that in dealing with the subject they had two enthusiasts to encounter—Dr. Letheby and Dr. Frankland—whose papers were always read with attention, and probably between the two some useful information might be gathered. He was disappointed in the paper just read, because it contained very little which was of practical benefit to the meeting as a body of sanitary officers. It raised objections to the existing modes of operation, but it gave them no hint as to what could be done with the sewage, how to utilize it without creating a nuisance, and exposing the community to those fatal consequences which Dr. Cobbold had described.

Mr. CREASY thought it was necessary to explain in some degree the sort of conflict of evidence which had taken place. When Beddington was mentioned, it should be known that it was a large district, and that a portion of it had little to do with the sewage question. The sewage fields of Croydon had been well chosen with reference to population, but certainly in every cottage on the estate there had been typhoid fever through the whole course of the time—not a cottage had escaped. And as to the outfall at Beddington Corner, every well was contaminated, and not a house was free from fever. At Carshalton he had had cases of enteric attack. At Beddington Corner, near the outfall, four children had been taken out of one house in a day stricken down with scarlet fever.

Dr. CARPENTER interposed the remark that the local nuisances in connexion with those cottages were quite sufficient to produce all the fever complained of, without seeking a cause in the outfall sewer a quarter of a mile off.

Mr. CREASY said that might be, but the watershed went in that direction. In every one of those houses an examination of the tongues of the inhabitants would show that there was enteric irritation. The same indications which were caused by the Croydon sewage on one spot arose from the existence of cesspools on another.

Mr. HAWKSLEY said he could fully justify the statements made by Mr. Creasy, for few persons were better acquainted than himself with the results of the irrigation works at Beddington Corner. He had been professionally called down to look at those works at intervals for many years, and also in consequence of complaints having arisen, although Dr. Carpenter stated that there had been no such complaints since 1860. When on other occasions he had been in the neighbourhood on totally different business he had taken samples of

the water as it fell into the Wandle, and had them analyzed. He had also been up the stream, and looked at the confluence of the two waters, which ran over the meadows in different directions. On one recent occasion he found one of those waters exceedingly clear, and the other about as foul as it could be. These two waters met, and passed down by the side of the cottages just mentioned, and thence to the Wandle. In the month of February last he was down there; the sewage was then frozen over the whole surface of the land for acres and acres, and was not in the state which Dr. Carpenter had described. But, besides that, he had been there in the summer, and in the summer it depended very much upon the state of the water as to whether the sewage, when passed upon the land, stank or not. In warm weather it often stank frightfully, especially on "muggy" evenings. The sewage then gave off a very sickening, though not necessarily a very powerful, odour. The same sort of thing occurred everywhere when sewage was applied to land—at the Barking farm, at Edinburgh, at Aldershot, and every place he had visited. It had been stated, to his great surprise, in the course of this discussion, that at Carlisle the sewage did not stink. Most assuredly it did in hot weather, although the entire quantity of sewage put upon the enormous acreage of land there was only from 200,000 gallons a day as a minimum, to something under 400,000 gallons as a maximum, which was only one-sixth of the sewage of Carlisle. And it was there of so little value that the other five-sixths were allowed to run away into the river, though the acreage of land for its reception was sufficient to utilize the whole. As to the commercial economy of the system, he had made a great many inquiries, and he had been told very frequently of crops being sold at £18,£20, and even £25 an acre, and that every one was delighted with the effects. But when he came to ask what was the net result of the year's working, he was answered, "Ah, that is another thing." "Well, but what is it?" "Well, we lost so many hundred pounds last year"—and in some cases so many thousands. There was not one single place he had heard of where the application of sewage for the purpose of sanitary disinfection was proved to be a commercial success. It was a commercial success at Edinburgh. Why? Because it was not applied for sanitary purposes. They used as much as they required for irrigation purposes, and the remainder ran into the sea or river nearly as foul as when it entered upon the land. But this was not the question now before the meeting. The question before them was one which almost every one could answer for himself. Take the case of plain irrigation by water only—pure water—water issuing, as in the majority of irrigation schemes in this country, from chalk springs. They all knew that when water was put upon land in certain seasons of the year in that state it did fertilize the land, and good grass crops ensued. But what was the result in a sanitary point of view? Fever and ague were produced. Go to Italy. He had been over all the irrigation works there, extending for 200 miles in one way, by 60 or 70 in the other, and what was the result? The people were in a state of actual decrepitude, not simply affected with fever, but with rheumatic complaints, and there was a great deal of cretinism. The same thing existed in the South of France, where irrigation by water only was adopted. Superadd to this foul organic matter, and what must be the result. He believed there was really nothing to be learned upon the subject. His own opinion was that of all unsanitary applications the most unsanitary was that of the application of sewage to land by way of irrigation.

Mr. CREASY said the Beddington grass was irrigated as long as it could stand up, and then it was sent away to market with the sewage some inches up the stem. So that if Dr. Cobbold was right there was an opportunity for the development of entozoa there.

Dr. LETHEBY, in bringing the discussion to a close, said he thought Mr. Holland had not quite apprehended the statements he had made. He had said all along that sewage going into a running stream where there was abundance of vegetation, fish, and a large quantity of oxygenated water, even in the condition of sedimentary sewage, was by a natural process quickly disposed of. But what he also said was that the main cause of all those nuisances which arose from the discharge of sewage into running streams was the sedimentary matter it contained, and that the distribution of sewage upon the land at the present time did not provide a remedy, and was accompanied by a large number of disadvantages. He said, further, that there was another means whereby these sedimentary matters could be separated—that by a process of chemical precipitation, as by lime, sulphate of alumina, or the agents employed by the A.B.C. Company, or that recommended by Mr. Blyth, they had the power to do certainly, and without danger, what they were not doing certainly when the sewage was put on the land, and with a great deal of danger. By this system of precipitation they could separate those solid elements and could superadd agents which were not particularly injurious to the highest forms of animal life, but were deadly to those creatures referred to. There was indeed a mode within their reach of dealing with those sedimentary matters which were the real cause of nuisance by accumulating in the rivers, and of rendering the water in such a condition that it might safely be admitted into a stream of eight or ten times its volume. It was a fact that in every one of the places visited, where the irrigation system was adopted, they found—whether by accident or design—abundant evidence of those evil results which it was most desirable they should seek to avoid. The system of precipitation, by chemical processes, could, however, be carried on without the slightest danger to the public, but this could not be said of any system of irrigation; for it was indisputable, from the investigations of Dr. Murchison, that sewer gases would produce sewer fever; and as these gases are abundantly evolved from irrigated land, no doubt it was a question open to a great deal of discussion as to how far they must be diluted before they would cease to produce dangerous consequences. He had told them what he found in his own experience at a model place—the Hebble Brook—where the inhabitants were so decimated by fever that the system was obliged to be stopped. He was asked whether the sewage then was to be wholly lost, and not utilized upon the land? He hoped he had sufficiently answered those questions by showing that the proposed mode of dealing with it was open to the objections that it was dangerous and uncertain, and that there were other better means of dealing with it. He did not mean to say that by irrigation sewage could not be defœcated, but he contended that the system required great attention, and that the result could not be realized in practice; whereas, by the adoption of chemical processes, there was a safe and certain mode of accomplishing the object, and, so far as he knew, these processes were more economical, for there was not a single instance in the country in which the utilization of sewage by irrigation had proved profitable.

On the motion of Mr. Liddle, a vote of thanks was given to Dr. Letheby for his paper, and the proceedings terminated.

Treatment of Orchitis by Blistering.

In a recent number of the *Pacific Medical Journal*, Dr Cooper mentions a case under his care. It was that of a young officer who had just contracted gonorrhœa of the virulent type prevailing among the Indians. It being a fresh case, and the first attack, I thought it a fit one for the so-called "abortive" mode of treatment. I therefore injected at once a strong solution of nitrate of silver, taking good care to prevent it from passing farther back than the scrotum. The pain caused was intense for some hours; but the desired effect of destroying the virus was not produced, for soon after violent orchitis came on, either from the natural course of the disease or from its being "driven back," literally or metaphorically. This new inflammation was so severe as to deprive the patient of rest and almost of reason, while the necessity of his very soon taking the saddle made it important to act energetically. Fearing the delay required by the usual modes of treatment, I decided on counter-irritation as the quickest, and having none of the more rapid vesicants at hand, applied the Emplast. cantharidis 4+4 inches, on the inner surface of each thigh near the groin. As soon as vesication commenced the orchitis began to subside, and in a few hours was quite relieved and did not return. I may add that the vesication extended to a considerable part of the scrotum, but I had no doubt that the more distant blistering was the cause of the relief experienced.

The gonorrhœa returned, and was treated by milder means with success, but whether any ultimate effects followed the disease, I have never ascertained.

New Hospital for Bolton.—The late Mr. Stephen Blair, formerly M.P. for Bolton, leaves £20,000 to build and furnish an hospital for Bolton; and he further bequeaths to the trustees of his will a sum of £10,000 to be invested, so that the income may form an endowment for the hospital, and desires that the hospital be called "The Blair Hospital."

WEDNESDAY, JULY 20, 1870.

THE OBSTETRICAL SOCIETY ON INFANTILE MORTALITY AND BABY-FARMS.

Dr. Farr of the Registrar-General's office applied some time ago to the London Obstetrical Society for information upon the question of infantile mortality, a subject he has thrown much light upon. Infant mortality is much higher in the southern countries of Europe than in the northern, according to Dr. Farr; greatest in Italy, lowest in Norway. One of the first questions the Society had to reply to was, as to the number of cases of labour attended by women in different localities. This varies greatly. As much as 75 per cent. are attended by midwives in Glasgow, in Coventry 90 per cent., in the east of London from 30 to 50 per cent. In the west end very few midwives exist. It appears that in this country the married poor habitually suckle their children and often protract this lactation period until the child attains the age of two years, "for the most part with the hope that it may prevent a rapid return of pregnancy." Illegitimate children among the poor are rarely suckled; but nearly always brought up by artificial food, consisting frequently of bread soaked in water or milk, and sweetened arrowroot, sago, or corn-flour, baked flour and biscuit food; all generally of too substantial a consistency, and too exclusively farinaceous. When nearly a year old many infants are fed with all sorts of absurd articles of diet, such as vegetables, fruit, meat, salt fish, cheese, pastry, and beer. Dosing babies with anodynes is very prevalent; in Long Sutton, for instance, with a population of 600, one chemist sells 25½ gallons of "Godfrey's Cordial" annually, and laudanum, paregoric, syrup of poppies and Steedman's powders are used most extensively. Gin, too, is greatly administered to babies in large towns.

Children are not frequently sent out to nurse in this country, save in the case of illegitimate ones. The grandparents seem to nurse the child most frequently in agricultural districts. Baby-farming seems almost peculiar to London. At Wimbledon, however, it appears to be frequent, as it is throughout the western parts of the metropolis. The desertion of children, especially of illegitimate ones, appears to be far from uncommon. Desertion of illegitimate children is frequent in London; the mother being anxious to get rid both of the pecuniary burden connected with the support of the child, and of the evidence of her having had a baby. She frequently then leaves the child with the woman who undertakes to nurse it, and the ultimate lot of the child thus deserted is either death by slow starvation, or the workhouse. In some cases again, illegitimacy is not much discountenanced, and women have five or six illegitimate children. The Brixton baby-farm has of late attracted public attention, and the thoughtful mind will see at once that the death of that half-dozen of children has a great importance as indicating a certain state of social life, and suggesting the idea that the fate of those particular children may be multiplied by an unknown quantity. That baby-farms directly owe their existence to the birth of illegitimate children will hardly be doubted; but a fact of more complex origin and against the dictates of natural instinct, is the separation between parent and child, which ensues when the latter is placed at a baby-farm. The statistics of illegitimacy in this kingdom would seem to show that about 1 in 13 of all births are illegitimate, and, therefore, there are a large number of poor mothers from whom the society in which they move demands one of three sacrifices—either 1, to retain the charge of the child and be scouted for life by that society; or 2, to keep the child's existence a secret and retain their social position; or 3, more rarely society allows itself to wink at the act of the offender if (a daily reiterated falsehood) the name of aunt, nephew, or niece, be substituted for the true relationship. The second of these alternatives is usually chosen, and necessitates the giving up of the child into the hands of strangers, the mother seldom or never seeing it; hence, alienation of affection speedily takes place. The then possessors of the infant frequently neglect it, often having, in addition, a pecuniary interest in its death. To obviate these evils, the compassionate in most countries have, from time to time, instituted "Homes" and "Foundling hospitals;" but the medical observer, we hold, cannot conscientiously approve of such institutions when he daily witnesses the hazard of artificial feeding, and the evils of overcrowding of children—circumstances not brought home to the minds of the charitable founders of such places. The French system of the "crêche" would here in England be almost useless, as it only retains the child a few hours daily, and thus secrecy could not be maintained. Holding, then, that separation of the child from the mother lessens so immensely its chances of life, the question arises why society demands the sacrifice? Its reason for so doing is professedly to punish the wrong doer, but surely it might be well to reconsider whether a punishment, the carrying out of which brings about so much practical child murder, would not be better let alone. Society, if bent on reform, might still find ample scope for its energy, in raising the standard of parental care. Remembering the wide-spread ignorance of the mass of the public, and of women especially, as to the conditions essential to healthy child-development, it might, by disseminating hygienic knowledge,

bring home to the minds of parents the baneful results of such a separation, for we fancy that the majority of women would shrink from a course of action which, under wider knowledge, would appear in its true light of infanticide. Thus, the child having been born, the chance of its welfare might come to be deemed more important than the favour of society, which bears so unjustly upon the weaker party, the mother. Society might then turn its attention to the fact that even amongst legitimate children death constantly results from neglect of favourable sanitary conditions; and it might justly censure the severing of parents and children by the former residing in climates, such as India, where children cannot be successfully reared, or the banishment of children to boarding schools for many years of their life, where they are so often ill-fed and over-worked. As a rule, says the report of the Obstetrical Society, many illegitimate children die under the first year, as many as 26 per cent. in Wakefield; but, in Norfolk, Mr. Waller, of Flegg-Burg writes, "Although in this county as regards illegitimate births we stand highest but one, *i.e.*, Cornwall, the lives of illegitimates in my district are, at all events, as good as of legitimates." Norfolk seems, then, to be a humane county. In London 75 per cent. of illegitimates die before reaching one year of age.

With regard to the means of preventing the large mortality among infants, all agree in the importance of mothers suckling their children for some months, and on the mischief which arises from the practice of giving infants of but a few weeks old solid farinaceous food, not to speak of coarse diet. When the mother cannot suckle, from whatever cause, no food beyond milk and water, provided the milk be of good quality, should be given to the infant for at least the first three months. Education of mothers would save many deaths and abstinence from the use of cordials. As to the enormous mortality among illegitimate children in London and elsewhere, it requires no conjuror to account for it. If society will be so severe against the begetting of one or two illegitimate children by single women, whilst it gives its sanction to the large families of other women, who, in the eyes of good Malthusians, do so much more harm than the former, in lowering the rate of wages by the introduction of so many new members into society, it must expect to be obeyed, and to have much infantile mortality. The single woman does not take care of her child or love and cherish it, in case she may lose her situation or be prevented from the chance of attaining the only prize of social life that is left to most women—matrimony. Ages to come will read the report of the Obstetrical Society with astonishment and horror, and exclaim, These were, indeed, terrible days for women to live in!

SCOTLAND.

A MEETING of the Edinburgh University Court was held on Thursday last, when the recent election to the Chair of Midwifery was brought before the members of the court by Principal Sir Alexander Grant. In the course of a speech of considerable length, Sir Alexander, in urging the necessity of a reform in the constitution of the Court of Curators, said that, having regard to the future, it appeared to him absolutely necessary to guard against the possibility of elections being decided by party feelings in a Court which was constituted in the very peculiar way in which the Curatorial Court was. It was absolutely necessary to have a Court which would justify itself to the public. Without such a Court there must be a want of confidence and that might be a very serious matter to the University. The University had recently sustained more than one severe loss through death—illustrious men had been removed from amongst us. The University was exposed, too, to great competition in sister Universities in the country, and in schools of science of all kinds which were rising up under the patronage of the Kensington Institution, and under the patronage of the Government; and it was therefore of vital consequence that, whenever vacancies occurred, men of the greatest scientific eminence should be secured to fill them. But when an occurrence such as the recent election took place, confidence was somewhat shaken; and it seemed to him doubtful whether they could expect the best men to submit themselves to a tribunal which was felt to be so unsatisfactory. He spoke in regard to the future. He thought it was quite clear that the time had come when a change should be made in the Board of Curators; and he submitted to the members of the Court whether it would not be befitting for them to take some steps to bring about that change.

Professor Christison entirely concurred in the remarks which had been made by Sir Alexander Grant. The recent election had caused, not only in the medical profession, but amongst the educated classes of the community generally, almost universal dissatisfaction. There was a great disparity of qualification upon the occasion; but no attention was paid to that disparity by the majority of the Curators. His opinion had always been that the Board of Curators was an improperly constituted Court; and some change was absolutely necessary.

The other members of the Board, with the exception of the Lord Provost, who was absent, concurred with the Principal and a discussion took place as to the course to be pursued. On the suggestion of the Lord Rector, the Principal gave notice of the following motion for next meeting:—"That the Court shall take steps, in whatever way may be thought most proper, to obtain a change in clause 13 of the Universities Act, which provides for the constitution of the Board of Curators."

At the same meeting an application was read from Dr. Matthews Duncan to the effect that attendance upon a course of lectures on Midwifery, which he intended to commence in November, should be recognised by the Court as qualifying for graduation in medicine in the University. A similar application was submitted by Dr. Keiller. The applications were granted.

LADY STUDENTS.—At a meeting of the lecturers of Surgeons' Hall, Edinburgh, the following resolutions were passed on the motion of Dr. Arthur Gamgee, seconded by Dr. Stevenson Macadam:—"1. That it is expedient that lecturers in this medical school should be free to lecture to female as well as to male students. 2. That no restrictions be imposed upon lecturers as to the manner in which instruction is to be imparted to women."

THE Edinburgh Infirmary Act having received the Royal assent, the acting committee of contributors have resolved to hand over to the managers of the Royal Infirmary the proceeds of the public subscription. The amount is estimated at £160,000.

THE annual meeting of the Forfarshire Medical Association was held at Arbroath on Thursday, the 7th. A large number of members were present, including Professor Christison, Edinburgh; Professor Inglis, Aberdeen; Dr. Luke, and others. At the dinner which was held after the meeting, Dr. James Arrot, who presided, in proposing "Prosperity to the University of Edinburgh," took occasion to animadvert strongly on the mode of filling up the chairs in that University as exemplified in the recent election to the Midwifery Chair, which had occasioned such deep and wide-spread dissatisfaction. He thought the time had come for divesting Town Councillors *in toto* of all power and voice in such appointments. He was sure

that the University of Edinburgh had the best wishes of the meeting for its continued celebrity and usefulness. (Cheers.) Professor Christison, Edinburgh, who was present as a guest, in replying to the toast, said he was not like some people who set no value on good wishes, for he thought they were not unfrequently the precursors to good luck. The evil to which Dr. Arrot had alluded in the mode of filling up chairs in the Edinburgh University had, he trusted, now reached its acme; and when matters reached their worst there was hope they would mend. He trusted some such change as had been wished for would take place soon. So long as Town Councillors have to do with these elections, motives altogether apart from the merits of the candidates will influence their conduct. When he was elected a Professor, now thirty-eight years ago, there were thirty-three Town Councillors, and he had often mentioned in private, what he now stated publicly, that of those who supported him only two did so because they thought him the best man.

Notes on Current Topics.

Mushroom Eating.

We are getting into the season for gathering and consuming mushrooms. Within the past few days we have seen a well marked case wherein a husband and wife, who had partaken of mushrooms with their tea, which, no doubt, had been mixed up with poisonous fungi, were seized with the characteristic symptoms of cryptogamic poisoning—the sense of sinking, and impending dissolution, accompanied by cold perspirations, &c. An extract from a new book, "Every-day Objects," descriptive of the means of recognising the true mushroom from the false, the edible from the poisonous, will, we conceive, be useful at this season :—"The *true* mushroom as it develops itself ruptures the ovoid wrapper or vulva, leaving the remains entirely at the base of the pedicel; whilst in the false mushroom the *debris* of the vulva are found not only at the base of the pedicel, as in the real Agaric, but even upon the red surface of the pileus itself. These are the white irregular warts characteristic of the Amanita, but wholly wanting in the Agaricus. Then, there are two Amanitas, the Amanita muscaria, or 'fly agaric,' and the Amanita amastica, or, as the English botanists call it, Agaricus Cæsareus, the imperial mushroom." To this we would add, the sweet, delicate odour of the edible mushroom, which contrasts with the scentless, dangerous fungi, or the poisonous cryptogam possessing a dull heavy smell. The inexperienced, we hold, should not risk their lives for the sake of this delicacy; but if the extract we have quoted be carefully observed, we consider there will be little danger in mistaking the true from the deleterious mushroom, and less liability to error with its consequent danger to life.

Baby-Farming.

The publication in the *Times* of a letter signed "A.B.," purporting to be written by a lady, and giving an account of visits made to baby-farms two years ago, marks an era in the agitation that has been caused by modern revelations of English life. It is not likely that the Editor of the *Times* would admit a letter extending over several columns without ample guarantees of good faith, and yet some of the statements made are as likely to excite incredulity as indignation. We were prepared for horrible revelations as to the women who engage in the trade—but how about the medical men said to be implicated? "A.B." while accusing practitioners, and presuming, because they called themselves doctors, that they were duly qualified (how unjustifiable a presumption medical reformers know too well!), takes especial care to conceal the locality of the establishments. It is impossible to guess whether North, South, East, or West of London was visited, and the names of all the persons said to be doing a fine trade in murder are withheld. It is certainly a question whether "A.B." should not have communicated with a magistrate at the time, instead of reserving the revelations for a couple of years, and then only using them to create a sensation. Casuists will not fail to find in her conduct many a nice point both of law and morals. On the part of the Profession we can only say that, though there may be here and there a black sheep, it would be a relief to have the data furnished by which we might ascertain whether those pointed at are really qualified practitioners, or only those infamous quacks of which we should only be too glad for the Legislature to rid us. Will not "A.B." show her sincerity by helping us in this? Such particulars would be far more valuable than elaborate descriptions of the costumes in which she made her pilgrimages. It is utterly impossible to put down crime by accounts of amateur excursions into the regions where it abounds.

No doubt, she wasted hours to rouse public attention to the evil, and such statements cannot but arouse attention even when wars and rumours of wars occupy the public mind. Still, mere assertions, without proof, are of little value; for it may be fairly argued that facilities to place children out to nurse are almost necessary in the present state of society.

We have reason to believe that a number of men calling themselves doctors, but without the shadow of a right to do so, are engaged in the most infamous part of this traffic in infantile life, and whoever will assist to bring such scoundrels to justice will receive our hearty sympathy and support. It is no secret that the whole Profession is unanimous in its desire for such self-government and such power as would enable it to separate its members from all dishonourable persons; but if the Legislature will not give us this power, and if the public persist in considering a brass-plate proof of medical qualifications, who is to blame? We suffer—but the fault is not ours.

Dr. Burrows.

This gentleman has been appointed Physician-Extraordinary to the Queen. No one more fully deserves Court recognition than this able physician, scholar, and medical reformer. His presidency of the General Medical Council gave universal satisfaction, and we know that he would have been very glad to carry the reform in the constitution of that body, on which we have so often insisted. He had worked hard, too, in the cause of medical reform long years before the Council was instituted. In honouring him the Court honours the Profession. We should have been glad to hear that further honour had been offered him. Court recognition of our Profession is far too rare.

A Very Sad Spectacle.

Patience and tact—gifts with which the indefatigable Coroner for Middlesex (Dr. Lankester) is so largely endowed—were sorely put to the test on Monday, the 11th

instant, at an inquest held on the body of William Thorn, Wellesley street, Seymour street, St. Pancras.

Strange to say, the inquiry was sought by one of the medical attendants on deceased; and judging from the repeated attempts made by him to tamper with the principal witness—Mrs. Thorn—whilst under examination, coupled with insubordinate discourtesy to the coroner, and unphilanthropic hints as to blighted hopes of an equivalent in recognition for services said to have been rendered to deceased, we are reluctantly compelled to declare that the motives which induced the inquiry appeared to display less of a purely pathological character than of a parsimonious and a personal one.

The evidence of Mrs. Thorn was to the effect that for upwards of two years her deceased husband had been in bad health; that in November last one of his eyes was extracted; that he had an epileptic seizure; that from that time until the fatal termination of the case (which occurred seven or eight days subsequently—a doubt about this being employed) he was visited daily, with one exception, by Mr. William Turnbull, surgeon, at whose instigation the inquiry was now being held; that during the attendance of Mr. Turnbull she obtained a parish order, consequently her husband was visited by Dr. Thompson, one of the district medical officers, and by his assistant; that she received medicine from them; that these gentlemen were *not* aware of Mr. Turnbull's attendance, but that the *latter was aware* of the attendance of the former; that Mr. Turnbull supplied medicine up to the death of her husband; that such medicine was administered to him, on the advice of Mr. Turnbull, in preference to the parish medicine; and, alas! because witness was of opinion that if she administered both medicines they would "mix and do no good." Now, there was no attempt made by Mr. Turnbull to deny this statement; so far from doing it, that gentleman reiterated much of it, and dwelt in words emphatic, if not precise, on what he ordered to be done, what he did, and what he didn't in the matter, and how "Thompson would be paid for it"—a state of things scarcely to be deplored under the circumstances.

Having heard the evidence of Dr. J. E. D. Rodgers—deputed by Dr. Lankester to make a *post-mortem* examination—and subequently the evidence of Mr. Turnbull, the proceedings were prematurely brought to a close, both jury and coroner expressing an unanimous opinion that there was no necessity for Dr. Thompson to trouble himself by offering any explanation as to his acts, and those of his assistants in the case, the widow of deceased and Mr. Turnbull having themselves sworn that deceased received every attention—in fact, profuse medical attention—and that death resulted from "congestion of brain, and natural causes." A verdict in acccrdance was recorded.

This terminated a senseless, useless, and, we wish we might add, an *objectless* inquiry. The object aimed at, undoubtedly, was professional scandal; the object attained complete vindication of Dr. Thompson; but with it, alas! a lowering of our professional status in public opinion.

But there is a moral in those proceedings, and it is this: that it presents to the Profession a still further illustration of the anomalous position in which at any time medical men may be placed by a designing knave, a fool, or a busy-body, to gratify a grudge or to promote ulterior ambitious views—ephemeral as they may be—by seizing on a reputation patiently, industriously, and guilelessly earned; earned too in a field wherein worldly rewards are few, praise scant, responsibility great, and toil unceasing; and holding it up to the gaze of perhaps a scornful or insatiable herd.

The Usurpation of the College of Surgeons.

The Council of the Royal College of Surgeons of England has consummated its crime. It has proceeded to appoint Mr. Quain as member (for the College) in the General Medical Council. There is only one redeeming point about it. Some members of the Council opposed this act, and stated that the fellows and members had the right to elect. This we have long argued. It was, as our readers know, first stated by Dr. Prosser James; and we are informed that that gentleman has taken counsel's opinion on the point, and that this opinion is entirely in favour of his view of the law. If Mr. Quain pretends to speak in the name of the fellows and members he will deserve to be called an impostor.

The Medical Club.

The general meeting we announced took place last week and was well attended. More than 130 members had written to express their willingness to increase their annual subscriptions as proposed to five guineas for town and three guineas for country members. We should hope that the many advantages held out by the club will be more fully appreciated, and that many will join it. It is a matter of importance that the Profession should support a club, and surely the large numbers of medical men who belong to general clubs will also join their own. Those, too, who only want a single club, ought to support this.

The Medical Bill.

To-morrow (Thursday) is the day fixed for the second reading in the House of Commons. Dr. Lush—all honour to him!—will move that it be read that day three months. Sir J. Gray's Bill will be considered at the same time. Dr. Brewer has also a measure. Nothing will satisfy the Profession or be of any use to the public but the one portal and representation in the Medical Council. These are the only two things worth asking for. If denied, let us wait another year.

The Irish Registration System.

Some months ago we had occasion to notice the argument put forward on the part of the English Poor-law Medical Officers' Association in favour of the introduction of the Irish Medical Charities and Registration systems into England. Without in the least desiring to imply that those systems might not be an improvement on the existing English Poor-law Medical mechanism, or at all intending to discourage the advocates of the introduction of these systems, we still retain our opinion that it would be very unfortunate that the English Poor-law Medical Officers should be unacquainted with the shortcomings and *desagrémens* of the Irish system. It is unnecessary for us to enter into detail of the many and great discomforts and the very inadequate rewards which the Irish Dispensary system devolves on its medical staff. Whether those shortcomings are greater or less than those which notoriously attach to the English system it is not necessary for us now to declare. Suffice it to say the Irish system

is, as far as its medical officers are concerned, very far indeed from being either remunerative, pleasant, or effective, and to publicly represent it as being so is not only an inaccuracy but an injustice to those who have for so many years struggled for its amendment.

The last report of the Registrar General for Ireland affords us an opportunity of showing that, in the public interest, the Irish Registration system, as it at present exists, ought not to be extended. It is, as our readers are aware, in the hands of the Poor-law Medical Officers, and we observe, with much regret, that under their administration it is as unreliable and unsatisfactory as it well can be. The proportions of births and deaths registered in Ireland within the last quarter are respectively 1 in 34 and 1 in 49. Those in England for the same term are respectively 1 in 29 and 1 in 44. This discrepancy between two countries in which we know of no real difference, is easily accounted for by the fact that in some districts the proportion of births registered is as high as 1 in 22, while in others it does not amount to more than 1 in 103—statistics which amply prove that in certain places not more than one fifth of the actual births are ever recorded. In referring to this state of things the Irish Registrar-General says:—"It is evident from the foregoing figures that the registration of births and deaths is very imperfect. The registration of marriages, it is greatly to be regretted, is still more unsatisfactory."

Annihilation of Small-pox in Ireland.

The Irish Poor-law Commissioners in their last report refer in the following terms to the cessation of small-pox in Ireland:—"The number of deaths by small-pox occurring in the workhouses during the fifty-two weeks is seen to have been only one, following upon three in the last year, and five in the preceding year. These facts, taken in connection with the Registrar-General's Quarterly Returns, and the information supplied to us by the medical officers of workhouses and dispensaries, enable us to say with confidence that small-pox is scarcely any longer to be regarded as indigenous in Ireland, and that it exists occasionally only by introduction from beyond sea, for the inoculator appears to have ceased his dangerous trade altogether. The modes of introduction which experience teaches us most to apprehend are sailors arriving in Irish ports from Great Britain or the Continent, soldiers returned from furlough, tramps and vagrants crossing the Channel to change the field of their operations, and lastly, poor persons compulsorily removed to Ireland from British towns, such as London, Liverpool, Glasgow, and others, where small-pox is always present."

Changes of Temperature in Typhoid Fever.

M. Garcin, of Marseilles, has published, on the authority of Professor Fabre, a series of observations of great value and importance on temperature in typhoid fever. There is, it appears, a distinct relation between the temperature and the intestinal lesion. As long as the intestinal glands are infiltrated and swollen, the thermometric rise is constant; whilst they are ulcerated, the thermometer is stationary, and is in a remarkable manner subject to peculiar changes. If the products of the ulceration are in course of elimination, the temperature is uniform. If, on the contrary, the septic products are absorbed, pass into the blood, and cause poisoning, the interstitial combustion takes on new activity, the temperature again rises, and finally the descent of the thermometer indicates the repair of the intestinal lesions.

The Sewing Machine, and its Effect on Health.

It will be recollected how, about a year ago, one of our medical contemporaries, in sequence to its delusion about the gregarines, gravely announced that the use of sewing machines was destructive of health, and more than hinted that those who used them became shortly the subjects of ovarian excitements of an undesirable character. This alarm, being a novelty, was echoed by the daily press, and the sewing machine was in danger of being tabooed, when a reliable authority declared that the alarming predictions were purely chimerical. The matter has been conclusively disposed of in a communication laid before the Paris Academy on the 21st of June by M. Decaisne. His conclusions, from an observation of 661 workwomen, are shortly as follow:—

1. The effects on the locomotor system do not differ from those of excessive muscular exercise of certain limbs to the exclusion of the others. The effects of the fatigue do not exist in women who work only two or three hours a day, and disappear in a short time in the case of those who work longer hours.

2. The digestive disorders common to sixteen out of every twenty artisans of Paris, are not more common in machine sewers than in other trades.

3. Affections of respiration are not more usual in them than in those who use the needle.

4. The influence on the nervous system, supposed to be caused by the noise, is slight; for the workpeople soon become accustomed to it, and it has no effect on their health.

5. Without positively declaring that the sewing machine does not cause genital excitement, I am quite certain that the cases published and the generalisations on them have no value whatever. The result has been found to be very seldom the effect of the machine, and I have almost uniformly found, in previous habits or special physical condition, good reason for the forms of excitement to which I allude.

6. Careful investigation has proved that machinists are not more subject to menorrhagia, miscarriages, peritonitis, or leucorrhea, than other workwomen.

In conclusion, I find that the sewing machine, worked by the foot, when used within reasonable limits, involves no more danger to health than the use of the needle. This is sufficiently testified by the fact, that among twenty-eight women from eighteen to forty years of age, working three to four hours daily, it was impossible to detect any effect attributable to the sewing machine.

Peers and Doctors.

We have a note or two from the House of Peers:—

1. The Earl of Lichfield remarked that the Profession had no voice in the Colleges and Universities, and therefore should have a direct voice in electing the Medical Council. We regret he did not go further and say that a voice ought to be given in Colleges and Universities to the members and graduates. In the case of the latter they do vote for the Member of Parliament. Why not for a representative in the Council?

2. Earl de Grey repeatedly contradicted his own state-

ments, proved himself ignorant of many questions involved, and determined to resist the just claims of the Profession. He is opposed, also, to giving the Council too much power. In fact, it is clear his first proposal expresses his wish, viz., to make the Council the mere tool of the officials of the Privy Council.

3. The Marquis of Clanricarde has defended the right of the Profession to representation, even to the extent of moving the rejection of the Bill. He has thus sown good seed which will be sure to bear fruit.

4. Earl Grey defended the right of the Profession as distinguished from the Corporations, to be represented, and thought Lord de Grey's observation, that the requisite machinery was not forthcoming, a just one. What a pity it did not occur to his Lordship that the machinery already exists in the case of the Universities, and that for the Colleges could be easily made similar!

5. The Marquis of Salisbury said the plan of electing by persons widely scattered had not been applied in any body in the country. Oh! most noble Marquis, were you not lately made Chancellor of the University of Oxford, graduates of which are "widely dispersed," and so forth? The Marquis also said he had not heard "that any of the more eminent members of the Profession were anxious for the proposed change." We beg to inform him that the Government Bill, as a whole, is so defective that no one of any thought in the Profession can care to wish it success; and that, as to the Medical Council, no one, except its own members, has a good word for it, and some of its own members themselves are anxious for a change. Why, the more eminent names may nearly all be found in the 10,000 signatures to a petition to Parliament that has long ago been presented.

The Doctor's Bill.

THERE are few less important subjects that concern our medical brethren than that of the Doctor's Bill. The public exact a great deal from the country practitioner; they expect great attention, and consider it the doctor's duty to cure them in every instance. If the nature of the case renders him unsuccessful, sometimes they are only too ready to attribute it to want of skill, and never consult his feelings in the insinuating remarks which have for their object the calling in of a town consultant who gets as much in a single fee as the whole treatment of the case perhaps amounts to, or in superseding altogether the medical attendant, who has left nothing undone that science could suggest or experience, dictate by bringing to the bedside of his patient the herbalist or the panderer to homœopathy. Again, the doctor with much zeal, anxiety, care, and personal risk may bring a whole family through a serious illness of contagious disease; from his own table and cellar supply them with little luxuries which he may think will tempt the fastidious appetite; or he may sit by the bedside of a woman in parturition hour after hour throughout the weary night, encouraging and helping; or he may perform operations requiring great skill, nerve, and much subsequent attention, and yet find, when his modest bill is forwarded, grumbling and dissatisfaction. In the hour of danger the doctor is a great need; when he has performed his task worthily and successfully, his doings are soon forgotten, once he has restored his patient to health and usefulness. The remark very often made is, "Doctor, come as often as you consider it necessary; never study the expense, we'll pay liberally." This is only too familiar to the hard-working country practitioner, who, invariably to his disappointment, as a rule finds it turn out so much "sounding brass and tinkling cymbal." The doctor's work, we repeat, the doctor's skill, his risk in contracting disease in the deserted chamber of the fever patient, or his personal danger in the self-infliction of an injury in the performance of an operation, are never considered. It is, "Oh, doctor, you charge me heavily; I have only had so many bottles of medicine!" We must freely acknowledge all this is brought about by a certain class of practitioner who reflects little credit upon his profession, and, whilst he lowers himself irremediably, so to speak, injures his brethren. We have seen doctors' accounts sent in like the chemists'—a mixture so much; a packet of powders, a box of pills, or a pot of cerate so much! This is objectionable. A practitioner should furnish a bill for professional attendance, and teach his patient that he does not, it is the chemist who charges for drugs; that his is for professional advice and professional attendance. We write of the general class of patients: there are many exceptions, many truly grateful, and generous patients, unforgetting and thankful for the attention paid them; but "one swallow does not make a summer."

We hope the following recommendations may prove useful to the general practitioner: The doctor's bill should be sent in early after the attendance, or many little circumstances become forgotten by the patient and his relatives. If the account be allowed to hang over, the debtor, again suffering from indisposition and needing professional assistance, may pass the door of his creditor because the account is unsettled, and consult another physician; or he may delay seeking help until his case becomes hazardous, for he is ashamed to meet the doctor whom he has not paid. The account should not be furnished as a chemist's, but the charges made specifically for advice and attendance, leaving medicines aside altogether. All midwifery fees should be expected to be paid at the next visit after delivery, for this is not like an illness; there is ample time to prepare for the event, and the most important individual connected with an accouchement should be the first to be considered, as his time is his living. Circumstances alter cases, but the most successful of practitioners adopt the rules we prescribe for the guidance of others.

A Safe Safe.

LAST week we inspected a new safe of dimensions that would astonish many; for it is a good sized room, in which one can walk about. It is the only one of the kind in the world, and perhaps the largest. It has been built by Messrs. Chatwood and Co., whose safes resisted all efforts to open them at the Paris Exhibition, but is an improvement even on them.

Moreover, it is surrounded by a pneumatic envelope, which is intended, not to resist burglars, but to detect their first effort. This pneumatic envelope consists of galvanized iron tanks, perfectly air-tight and connected with a gauge-index, which betrays in a moment any change in the water-level, and indicates at the same time the particular tank that is being tampered with.

Now, supposing any attempt, this index shows it before the safe can be touched; and as Chatwood's safes would require 70 or 80 hours' work, with every appliance, by a skilled workman, to force them, it is obvious that bur-

glars may give up the notion of penetrating this one. The pneumatic system of detection is the invention of Mr. T. W. Tobin, of the Polytechnic, a very ingenious gentleman, with whose name our readers have for some time been familiar. The safe has been erected for Mr. E. W. Streeter (of 37 Conduit street, London), the well-known introducer of machine-made jewellery, and more recently still of machine-made watches. The safe is intended not merely for his own stock of diamonds and valuables, but, being so large, Mr. Streeter will be able to take charge of the property of others, and he naturally supposes that many will be glad, for a small annual fee, to avail themselves of the chance of placing their jewels, &c., in such a safe.

Access to the safe is obtained by a doorway, 6ft. 3in. by 3ft., and 8in. thick ; the door weighs five tons. It is constructed of, 1st. The outer thickness of best "Dartmoor" iron, the back of which is intersected with thousands of cones, to receive. 2nd. "Speigelised" iron. 3rd The lock and machinery ; and 4th. The inner fire-proof covering. The front door is 18in. in thickness, and, with the substitution of fire-brick for the "Speigelised" iron, constructed much on the same principle.

The term "Speigelised" iron may be new to many, and, as this is not a general article of marketable supply, the following details may not be uninteresting :—

It consists of a hard combination of steel or iron, and silica or flint, possessing all the strength of the cast-iron ; it also resists by virtue of the flint any attempt to penetrate it with edged tools. A chisel tempered to cut the hardest metal is driven aside and burred like lead ; it would be, in fact, labour lost, endeavouring to bore or cut it.

The lock to close the safe is capable of several thousand alterations or combinations, in case the key is surreptitiously obtained possession of ; and, although the lock is of the largest kind, it is opened by a key no larger than that of an ordinary cash box ; with this and this key only can the lock be loosed.

The total weight of the safe, without its surroundings —simply taking the metal—is between 50 and 60 tons. The height is 9ft. 6in. ; width, 9ft. ; depth, 15ft.

The Late Dr. Copland, F.R.S.

We regret to announce the death of another veteran of our Profession. In his 80th year the author of the great "Dictionary of Medicine," with which his name must always be associated, died, last Wednesday, of hæmaturia. He had had a previous attack, but this one was soon followed by uræmia, under which he speedily sunk. His immense literary undertaking is the best proof of his indomitable perseverance and courage, and his almost unequalled learning.

The Friendly Societies Acts Burial Clubs.

A daily contemporary states that the proposed Royal Commission to inquire into the laws relating to Friendly Societies is being hotly opposed by the representatives of these societies on the ground that it will be injurious to the working classes. Just so. The representatives of those societies, with very few exceptions, have revelled for such a very great length of time on the hard earned pence of the poor, appropriating, squandering, and converting to all manner of vile uses, the moneys laudibly intended by the members or contributors for *that time* which sooner or later shall come to each of us (and which well-seasoned experience has taught many an anguished heart it would have been wise to be thriftily prepared for), therefore, they fear exposure and the ignominious rout sure to follow it. Let us hope that the Earl of Lichfield, the proposer of this Commission, and the numerous members of both Houses of Parliament that sympathise with the cheated industrious poor, will see that the Commission be not burked—even for a time—but that justice ample and complete be, even now at the eleventh hour, done them.

In London, lately, conferences of the moving spirits of many of these societies have been held, and a report has been industriously circulated, that in the proceedings of some of those conferences the Earl of Lichfield and other genuine philanthropists took active parts. If there be any truth in the rumour, in the interests of the poor we much regret this, for we really dread to think of the cunning devices that may be employed, and the glowing *water* colours that may be heavily laid on to hoodwink and seduce them.

Our remarks are intended to apply more particularly to the "sick and death benefit" and to the "burial club" sections of Friendly Societies Acts, than other sections of the really well-intentioned measure. Rotten at core as three-fourths of Sick and Burial Societies are, their odour sniffs savoury, compared to that emitted from these miasmatic seats of turbidness—Burial Clubs. There is no question but that the majority of Burial Clubs, *yet alive*, border on bankruptcy. Originally honestly intended to meet the wants of the lowest order of industrious poverty, whenever the great emergency arose for the employment of the sum the "penny a week" entitled the contributors to, they now appear to be sources whence managers, committees, and their agents "draw" from the very heart's blood of poverty the "penny a week" *and live on it.* The facility with which a dismissed policeman, an energetic tailor, a son of Crispin, or any "ne'er do weel' may be metamorphosed into an agent, canvasser, or collector to a "Burial Club," accounts for much of the wrong perpetrated by these "clubs" on the poor as the "sinews of war" are induced and collected by those persons, and finally passed to the hands of the managers of these clubs —*minus* commission for canvassing and collecting.

Until such time as a stringent Government supervision over Burial Club managers, committees, agents, collectors, canvassers, *et hoc genus omne*, be adopted, and the facility to cheat be restricted, by honest codes of rules and tables of benefits, by bi-annual examination of accounts, and seeing (*bona fide*) the securities (if any), and the actual monetary position of each club, and lastly by permitting none but persons of character (and giving ample security for its continuance) to be officially connected with them, the scheme will "pay" the cunning few at the sacrifice of honour, justice, and humanity.

A few days past the wife of a respectable farmer, named Purcell, residing at Feakle, attended by surgeon P. V. McDonough, gave birth to three children, all girls.

The meeting of gentlemen held in London to protest against the late appointment at the Edinburgh University, was largely attended, but many of those present were not graduates of the Edinburgh University.

The Cattle Diseases (Ireland) Bill passed with one or two amendments the third reading in the House of Lords on Thursday.

Out of the three hundred and ten candidates examined last month for the F.R.C.S. and M.R.C.S. of England, it is stated that about half of the number were rejected.

As will be seen on reference to our advertising columns, the subject for competition for the Alexander Memorial Prize for 1872 will be "Pulmonary Consumption as seen among Soldiers." The value of the prize is £50 and a gold medal value £10, and the competition limited to executive Army Medical Officers.

In this season of Continental travel it is worth while calling attention to the two cases narrated in the *Medical Mirror* of July, in which persons who have suffered in general great miseries in crossing the Channel, have been saved from sea-sickness by the use of Dr. Chapman's ice-bags. We intend making the experiment on some of our lady friends this summer. *Fiat experimentum.*

We are glad to see that Sir James Simpson's memorial is to be carried out according to the ideas of the illustrious deceased, and that the maternity institution is to be, as Sir Charles Trevelyan recommended, of the village form.

Sir Thos. Watson has been appointed one of the physicians in ordinary to H. M. the Queen, in consequence of the death of Sir J. Clark. The venerable baronet, as head of the Profession, was very naturally thus selected. If the Government would make him a life peer it would bring on a discussion that might end in a good reform in the House of Lords.

M. Auzias Turenne, the inventor and propagator of syphilization, has died in Paris. The medical journals report that a vast number of cicatrices resulting from chancrous inoculation were found on his body. A clause in his will stipulates that his body shall be dissected and his skeleton given to the Faculty of Medicine at Christiana, where his doctrines have found a firm adherent in the person of Professor Boeck, who is at this moment in America engaged in explaining the heterodox theories of his friend and master.

Dr. Villeneuve, after a lengthened inquiry, has published a long work on "The Proportion which exists between the Size of Children and their Vital Resistance in Normal Parturition." He has established, amongst other interesting facts, that of large children the number of boys is greater than that of girls, that the vital resistance of either boys or girls is in direct ratio to their development, that the deaths of mothers is the more rare in proportion as the children are larger, provided that the pelvis and the presentation are normal. Nothing would seem more reasonable to suppose, than that the larger the children are the greater the obstacles to birth they meet with. This is Simpson's theory, and it is a satisfaction to be assured that the hypothesis is incorrect.

Correspondence.

THE AMERICANS AND THE ETHER DISCOVERY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In the otherwise accurate synopsis of the history of surgical anæsthetics, by my friend, Dr. Hughes Bennett, in your journal of the 25th ult., I think I perceive one or two omissions that he himself would be glad to see supplied. Every man accustomed to large hospitals and large operations, must remember what a hideous thing the agony of such scenes and operations was before 1846, when Morton, for the first time in the history of the world, made anæsthesia a practicable, practical, and desirable fact. (I am afraid we must leave out Jackson.) Ether, a thing portable, old-fashioned, and familiar to everybody at once, like the lamp of Aladdin, was found to possess properties never suspected before, and chloric ether, used by Jacob Bell subsequently, and chloroform itself, recommended to Simpson (I am told by my esteemed friend, Dr. Tyler Smith, then editor of the *Lancet*) directly, by Dr. Formby and Mr. Waldie, and used previously by Flourens, differs, of course, very little from ether.

The great discovery was that of etherisation, by Morton, in 1846; it is scarcely fair to be going back to the mandragon of the classics or the virtues of puff-ball, voltaic narcotism, or even methyl-ethylic ether, in order to lessen the glory of Morton's discovery. The *Times* spreads the alleged fact through Europe that Simpson administered chloroform in 1844, and refuses all correction of the error, and that "a somebody named Morton, in 1846," pretended equal virtues for common ether; but this inversion of the facts is most unfair to America; nor is it correct to say John Bell, because he gave a soap-and-opium pill before an operation, had anticipated Morton, as Dr. Richardson does of late in the *Lancet*. We require very much just at present to have all the facts and dates fairly stated, especially that Dr. Formby and Mr. Waldie directly suggested chloroform to Sir James Simpson, and that it had been previously used by Flourens on animals to destroy sensibility before vivisection.

I am, &c.,

Sackville street, Piccadilly, June 1. Charles Kidd, M.D.

CONTAGIOUS DISEASES ACTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I conceive the letter addressed to Dr. Chas. Drysdale, and inserted in your last impression, from the pen of M. L. Lefort, is worthy of being replied to as far as it refers to the Contagious Diseases Act. M. Lefort sets out by asserting that the cause of prostitution in France is to be accounted for by the workman fearing to give up his liberty by entering into the marriage contract; and the woman, he affirms, does not expect it, because the looseness of morality (*relachement des mœurs*) makes no difference between the married and the concubine. So far so good. This we have exemplified at home. Anyone who ever had the misfortune to live in a manufacturing or colliery district of civilized England, can comprehend this remark of M. Lefort's; but when M. Lefort connects the dirty subject with the dogmatic morality Catholic societies teach, and writes about not being sufficiently educated to understand the laws of natural morality, thereby abandoning his religion and following the promptings of instinct, because of the difficulties he experiences in comprehending "*the absurdities of the Catholic religion,*" it is simply absurd. Take Catholic Ireland *par exemple;* the lower class are ignorant enough, God knows, but what is the effect of religion upon them? Is there a more virtuous people in the world? Let us, on the other hand, glance at the condition of certain districts in England, where cant is epidemic, and the piety tea-meeting lecturer, of the Richard Weaver, the converted collier, stamp, is in his youth, and what is the result? What greater insult to morality and *true religion* than connecting prostitution at all with it? It is, as M. Lefort states, *instinct* that leads to illegitimacy, and it is the nature of a certain race to follow it with uncontrolled passions. The illegitimacy, the prostitution, and depraved condition of our own people in manufacturing districts, is truly deplorable; but when preachers, like Richard Weaver, the fondling of old ladies, with a wife of his own, falls back into old habits of immorality, after a long term of conversions and revival demonstra-

tions, we are made to feel that it is our *nature* to be immoral, that facility of divorce can have nothing to do with it, and that if we know more of Catholicity and less of cant, the great evils of the age, abortion-mongers, baby-farmers, and professional murderers, would have no more existence in Protestant England than in Catholic Ireland.

I am, Sir,

Your obedient servant,

Osman House, Sutton, Notts, July 14th, 1870. J. WARING-CURRAN.

Resection of the Entire Scapula, with Preservation of a Useful Arm.

DR. SCHUPPERT records (*New Orleans Journal of Medicine*, Jan. 1870) a very interesting case of this. The subject of it was a stout unmarried German woman, aged thirty-six, who came to New Orleans in 1868, suffering from a large tumour comprising the right scapula, for which she had been twice operated on in Germany, which operations left the scapula intact. When seen by Dr. S., the skin covering the tumour showed many cicatrices from former operations. "The tumour from its posterior margin to the acromion process measured 0·18 metre, the largest extent in a vertical line being 0·21 metre. Active motions of the humerus were nearly arrested, the passive motions very much limited. The extremity could not be further removed from the body than to an angle of 45 degrees. The extensive pain the patient suffered in the arm brought her to me in search of relief. Having given her consent to a proposed removal of the entire bone, the operation was accordingly performed on the 30th of March, 1868, in presence of Drs. Barnes, Gray, Geutebruck, Riley, Schwarzwaelder, and some other medical gentlemen. Patient being in a deep chloroform narcosis, a crucial incision was made through the skin; one cut, beginning at the acromion process and carried over the most protuberant part of the tumour, ended near the spinal column; a second incision over the middle of the tumour bisected the first. The four skin flaps were dissected off and held back by sharp hooks. The acromion process was divided with a small saw, laying bare at the same time the scapulo-humeral articulation. The head of the humerus was then by rotating the arm dislocated inwards, to get at and remove the coracoid process. Lifting up the scapula by its glenoidal cavity, which was found to be involved in the disease, the whole of the scapula was detached from the body by keeping the knife close to the under surface of the tumour. The removal of the tumour left the ribs visible through the cellular tissue, which was all that remained of the subscapularis muscle, lost in the diseased mass.

The bleeding was inconsiderable, the main vessels having probably become obliterated by the former operations; with the exception of a few muscular branches no arteries had to be ligated. The skin flaps were adjusted and united by interrupted pin sutures, leaving an opening at the most dependent part to permit the draining of the secretion. Acetate of morphia, 0·03 gramme, was subcutaneously injected. After patient had perfectly recovered from the anæsthetic condition she was unconscious that the operation had been performed. The arm was bandaged and kept close to the body supported by a sling.

Patient suffered much nausea subsequently and vomited during several days from the effects of chloroform. No unfavourable symptoms happened to require medication. A nourishing diet was ordered from the first day and continued during the convalescent state.

The sutures were removed on the third day. Most of the incisions had healed by first intention. Suppuration was considerable, and notwithstanding the well draining of the wound two abscesses formed in the arm discharging a great quantity of pus. The wound was syringed out daily with glycerine containing ten per cent. of carbolic acid. On the 10th of June, the last secreting opening had closed.

At the present date, eighteen months after the operation, there is no indication of reappearance of the disease in any part of the body. The skin, of which no part had been removed, though after the excision of the tumour it formed a large sac, has so contracted that a part of the cicatrix forms now a portion of the covering of the humerus. Theresa, who enjoys excellent health, has thrown away the sling long ago, the arm has no artificial support, and is a more useful instrument than before the operation. Though its motions are limited, there is sufficient strength in the extremity to lift a weight of thirty pounds and throw it a fair distance.

The tumour weighed nearly six pounds and measured respectively 0·35 and 0·40 metre in circumference. From the original scapula but one third of the spine, a small portion of the coracoid process, and the centre of the glenoidal cavity remained intact; all the rest was involved in the growth. The tumour consisted of hyaline and fibro-cartilage with deposits of carbonate of lime in the interspaces of the cartilaginous tissue. Towards the centre, true ossification had taken place. We have to consider it, therefore, to be an osteochondroma.

Medical News.

University of Dublin.—The following degrees were conferred on the 6th inst:—*Doctor in Medicine:* John Smith Chartres, Henry Fitzgibbon, Henry Fitzsimons, Benjamin Johnston, Rawdon Macnamara (Honoris Causa), Frederick Orton, John Orton.—*Bachelor in Medicine:* Edw. Ebenezer Barrington, Armand Bernard, William Bolton, Sidney Herbert Carter, John Smith Chartres, Jacob Albert Clery, Abraham Colles, William Creery, William Hamilton Elliott, William Robinson Evans, William Jacob Fawcett, Charles Edward Hetherington, Francis Charles M'Nalty, Francis Geo. Mayberry, Jacob Samson Niven, Charles De Montmorency Palmer, Arthur Stopford Underhill, Richard White. — *Master in Surgery:* Edward John Archer, W. Battersby, Jacob Albert Clery, Richard Dane (Honoris Causa), William Jacob Fawcett, Charles Edward Hetherington, Francis Charles M'Nalty, Richard Rainsford, Arthur Stopford Underhill.—*Licentiate in Medicine and Surgery:* Cuthbert H. Huddart.

Sunstroke.—A student of Malvern College, Robert M. Drew, son of the Rev. W. H. Drew, Kings' College, died on the 7th inst., from the effects of sunstroke.

Female Medical Students.—We are informed the lecturers at Surgeons' hall Edinburgh, have adopted the following resolutions.—"1. That it is expedient that lectures in this medical school should be free to lecture to females as well as to male students. 2. That no restrictions be imposed upon lecturers as to the manner in which instruction is to be imparted to women."

Australian Leeches.—We learn from the *Melbourne Argus*, that a large consignment of leeches was forwarded to England in April of this year, per steamship "Somersetshire." We are informed that some parts of Australia abound with leeches, and those frequenting the Murray river have a good repute for biting freely, and leaving no inflammatory wound behind them. They are said quite to rival the speckled leech of Northern Europe. A Melbourne firm have contracted with the fishermen of the Murray district for the conservation of the leeches, and we understand that the contract for last season exceeded half-a-million. The leeches sent to England were packed in boxes of soft clay, made to resemble as much as possible the muddy bottom of the river, which was their resort.

Medical Officers' Poor Law Association.—Last week the annual meeting of this association was held at the Freemasons' Tavern. Dr. Rogers, who presided, read a paper detailing the effects of the amalgamation of this body with that of the Medical Reform Association. He submitted that adequate medical attendance tended more to reduce pauperism than any other plan. He congratulated the association on the signal success which had attended their efforts during the last two years. In July, 1868, there appeared to be absolutely no hope left for the parish doctor, save a life of ill-requited, unrecognised unhonoured toil, too frequently cut short by a premature death from disease contracted. A change from this state of things seemed to be opening up. Their grievances had been ventilated in the House of Commons, and in Mr. Goschen they had at last a president who had shown himself alive to the necessity of a reform of the system. He would be able to carry on the necessary reforms if his hands were duly strengthened by such united expressions of opinion as they and similar bodies were able to excite; but it was necessary that their efforts should be continued and not relaxed. The reader mentioned incidentally that poor-law medical officers were not unfrequently required to attend in their parochial capacity the servants of noblemen. A resolution was passed expressing

gratification at the action of the President of the Poor-law Board in his support of the Medical Officers' Superannuation Bill, and his efforts to establish permanency for parish as well as union medical officers. Thanks to the general officers and local honorary secretaries concluded the meeting.

Metropolitan Railway.—A scientific yet simple and inexpensive invention of Dr. I. McGregor Croft, has been tried on a first and second class carriage this week, by the assistant engineer of the line, for the purpose of rendering the air in the carriages cool and pleasant, and it is reported a complete success. No doubt all the carriages on this railway will be speedily altered in accordance with Dr. Crofts plans. The intense heat from the gas lights, and the oppressive atmosphere in the carriages, is a serious drawback to the company. This will be completely altered, and we congratulate one of the profession, for rendering such a boon to underground travellers, and trust the company will appreciate the inventor in a substantial way.

THE SIMPSON MEMORIAL.

A meeting of the Acting Committee was held on Friday afternoon in 5 St. Andrew Square, Edinburgh, Dr. Andrew Wood presiding. Councillor Colston intimated that the business would henceforth be carried on in No. 12 South Frederick street, as also that several large subscriptions had been received. Some conversation then took place on letters that had appeared in the newspapers and elsewhere, calling in question the propriety of the resolutions unanimously adopted at the last meeting of the Provisional Committee to establish an hospital for the treatment of the diseases of women as an important part of the memorial. The chairman and Dr. Moir, who were in constant attendance on Sir James Simpson during his last illness, bore the strongest testimony to the earnest desire expressed by him that a suitable hospital, where the sufferings of women might be relieved, and where students might have the opportunity of studying the treatment of this important class of diseases, should be open in connection with the Edinburgh Medical School, the want of this having always been felt by him as a great deficiency in its arrangements. It was announced that several of the large subscriptions would be withdrawn if the scheme of an hospital was abandoned. Dr. Alexander Wood, on behalf of the deputation, reported the proceedings which had taken place there, and spoke in strong terms of the cordial co-operation which they had met with.

NOTICES TO CORRESPONDENTS.

ERRATUM.—In Dr. Griffith's letter in our last, on "Entire Loss of Speech," for "*harsh* sentence," read *last* sentence.

DR. (?) NEWTON.—We extract the following admirable remarks from a very long letter of a correspondent, who writes, not in his defence, but in condemnation of the professional and public apathy with regard to quacks, as contrasted with the energy that has been displayed in persecuting this hapless but comparatively harmless individual. He says:—"Let me ask, are there not many really mischievous pretenders at work daily and hourly in this crowded, wealthy, and very virtuous (?) capital of the world, called London. And these quacks, charlatans, and other 'scoundrels' are allowed to go about unmolested, selling their poisonous wares, carrying on their deadly trades, and trapping the innocent and unwary to the imminent risk of body and soul. If inaction is very blameable, it is still more censurable to act as Dr. Newton's persecutors have done, that is, using their energies in one direction, instead of applying them to purposes which are likely to promote the good of their fellow creatures; they should first discriminate what is EVIL, and then let them suppress it with all their might."

J. C. P.—He certainly is not entitled to use the degree unless it be registered. If you will send us the name of the person, we will ascertain, if possible, who and what he really is.

WHAT DISPENSARY PRACTICE IS COMING TO.—An individual, whose address we are unable to find in the "Medical Directory," but who professes to be a qualified medical man, has recently opened a dispensary in London, where he may be consulted, and supplies patients with medicines at the rate of ONE SHILLING for three visits.

A SUBSCRIBER.—You can procure the American books named through Messrs. Trubner, Paternoster row, or your own bookseller will obtain them through that house.

VARICOSE VEINS OF THE LABIA MAJORA.—A Subscriber is desirous of being favoured with any recorded cases of this troublesome affection.

DR. LEARED.—Your paper "On Cancer of the Lung" will appear as soon as space permits.

PRUDENTIA.—Without the exact date we fear we cannot assist you to be copy you desire.

"On the Incubation Period of True Syphilis."—We regret that the article under the above title in our last issue was, by mistake, attributed to Dr. *Henry*, instead of Dr. *William* MacCormac.

VACANCIES.

London Hospital—Medical Clinical Assistant. Salary, £40.

Victoria Hospital for Sick Children—Resident Clinical Assistant.

Windsor Infirmary—House-Surgeon. Salary, £100, with residence, &c.

South Devon Hospital—House-Surgeon. Salary, £80, with board and residence.

Metropolitan Asylum District—Two Assistant Medical Officers, one each for Leavesden and Caterham. Salaries, each at £150, with board and residence.

Middlesex Lunatic Asylum—Assistant Medical Officer. Salary, £150, with board and residence.

Eastern Dispensary, Bath—Medical Officer. Salary, £80 with board and residence.

APPOINTMENTS.

ADAM, J., M.D., Medical Superintendent of the Metropolitan Asylum at Caterham.

ARMSTRONG, L., L.R.C.P., Surgeon to the Newcastle-upon-Tyne Infirmary.

BELL, H. R., F.R.C.S., Assistant-Surgeon to King's College Hospital.

CRESSWELL, T. H., M.R.C.S., Medical Officer for the Clifton District of the Tamworth Union, Staffordshire.

DAWSON, Dr. R., Physician in Ordinary to the Brighton Dispensary.

GIBB, C. J., M.D., Consulting-Surgeon to the Newcastle Infirmary.

HAMMOND, Mr., House-Surgeon to the Retford Dispensary.

HARMAN, E. J., Medical Officer for the Montiaghs Dispensary District of the Lurgan Union.

KERBEY, W. H., M.R.C.S., Medical Officer and Public Vaccinator for the Weobley District of the Weobley Union, Herefordshire.

LE TALL, W. J., M.R.C.S., Medical Officer and Public Vaccinator for the Handsworth District of the Sheffield Union.

WILLIAMS, W., M.D., Surgeon to the County Prison, Mold, Flintshire.

Birth.

REID.—On the 16th inst., at 3 Royal Marine road, Kingstown, the wife of Dr. Reid of a son.

Marriage.

WILLIAMS—SAVOURS.—On the 7th inst., at St. Paul's, Newport, Monmouthshire, Josiah Williams, L.R.C.P., to Rosina Margaret, only daughter of J. Savours, Esq., of Tynyrheol House, Neath, Glamorganshire.

Deaths.

ASPINALL.—On the 2nd inst., R. Aspinall, M.R.C.S.E., of Ebor House, Shipley, Yorkshire, aged 54.

LEE.—On the 10th inst., at Melville crescent, Edinburgh, James Lee, M.D., Surgeon-Major Bengal Army, retired list.

MACHILL.—On the 5th inst., Joseph Machill, M.R.C.S.E., of Pudsey, aged 56.

PHILLIPS.—On the 5th inst., at Adelaide road, N.W., Edward England Phillips, M.R.C.S., late of Bath, in the 56th year of his age.

THE ALEXANDER MEMORIAL FUND.

THE subject for the next PRIZE ESSAY will be "On the Nature and Varieties of Destructive Lung Diseases included under the head of 'PULMONARY CONSUMPTION' as seen among Soldiers, and the Hygienic conditions under which they occur. To be Illustrated as far as possible by Cases drawn from the personal observation of the Author."

CONDITIONS.

1.—A Prize of £50 and a Gold Medal value £10 to be awarded to the best Essay offered without reference to the number of Competitors, provided the Author has complied with the prescribed conditions.

2.—The Essay to be legibly and clearly written, superscribed with a brief Motto, and accompanied by a sealed envelope similarly superscribed, and containing the name and address of the Author.

3.—Essays to be despatched to the President, Alexander Memorial Fund Committee, Army Medical Department, 6 Whitehall Yard, on or before the 31st DECEMBER, 1872.

4.—The competition to be limited to Executive Medical Officers of the Army on full-pay.

5.—The relative merits of the Essays to be determined by Assessors to be selected by the Committee.

ST. PETER'S COLLEGIATE SCHOOL,

EATON SQUARE, S.W.

Head Master:—Rev. B. GIBSONE, M.A., B.Sc., Hon. Fell. King's Coll. Lond.

THE EXAMINATION for the MEDICAL SCHOLARSHIP commenced JULY 14th. The ELECTION and PRIZE DISTRIBUTION commences on JULY 28th, and the next term on SEPTEMBER 15th.

PUBLIC SCHOOL EDUCATION IN IRELAND.

COLLEGE OF ST. COLUMBA,

RATHFARNHAM, COUNTY DUBLIN.

VISITOR—The LORD PRIMATE.

THE COLLEGE IS intended for the EDUCATION of BOYS from the age of nine years and upwards. The Course of Instruction is of the same nature as that of the great Public Schools in England, in which Classical Studies are made the chief foundation. Particular attention is also paid to Mathematics, English, French, German, Drawing, and Vocal Music. Boys are prepared for the Universities of Dublin, Oxford, and Cambridge, and for the Competitive Examinations of the Military and Civil Services.

TERMS: For Boarders, 60 guineas; Younger Brothers are received at 40 guineas. A limited number of Sons of Clergymen will be received at 40 guineas. Terms for Day Boys, 20 guineas. There are no Extras.

There are Two Exhibitions attached to the School, tenable at the University of Dublin, value not less than £20 a year. Lists of the School, and of recent Honours gained by former Pupils, together with the Course of Study, and all other particulars, may be obtained on application to the Rev. ROBERT RICE, M.A., of Christ's Church, Oxford, Warden; or at Messrs. HODGES, FOSTER, & Co., Publishers to the University, 104 Grafton street, Dublin.

The Summer Vacation ends on Wednesday, August 10.

THE LONDON SURGICAL HOME,

FOR DISEASES AND ACCIDENTS OF WOMEN; for the Reception of Gentlewomen and Females of respectability, upon a weekly payment, under the sole management of Mr. BAKER BROWN.

The Private Medical Attendants of the patients are invited to visit them, and to meet in consultation before treatment.

Full particulars can be obtained on application to the LADY SUPERINTENDENT, Osnaburgh place, Regent's Park, London.

DRIFFOLD HOUSE ASYLUM,

SUTTON COLDFIELD, near BIRMINGHAM,

Beautifully situated in a very healthy and bracing climate.

LICENSED FOR PRIVATE PATIENTS OF BOTH SEXES.

For terms and other information, apply to the Proprietor,

G. F. BODINGTON, M.D., M.R.C.P., F.R.C.S. (Exam.)

CHURCH STRETTON PRIVATE ASYLUMS

FOR the UPPER and MIDDLE CLASSES of BOTH SEXES, are situated among the Shropshire Hills, Twelve Miles from Shrewsbury, on the rail to Hereford. Consulting Surgeon—W. J. Clement, Esq. M.P. for Shrewsbury. Physician and Surgeon—J. R. McClintock, Esq., M.D., late Assist.-Physician, Royal Asylum, Perth.

Apply to Wm. Hyslop, Esq., Stretton House, for Gentlemen; Mrs. Bakewell, the Grove, for Ladies. [Church Stretton, Shropshire.

TO INVALIDS.—MAISON DE SANTE,

No. 8 CHARLEMONT-STREET, DUBLIN.

THIS INSTITUTION HAS BEEN OPENED FOR THE reception and treatment of Patients of respectability, labouring under every form of Medical and Surgical Diseases, except Insanity.

No expense has been spared in fitting up for the purpose intended.

Prospectuses and every other information can be obtained from the Matron at the Institution, or any of the Medical attendants:—

Dr. J. F. Duncan, 8 Upper Merrion-street; Dr. Quinan 29 Leeson-street; Dr. Walsh, 89 Harcourt-street; Dr. Ward, 1 Rathmines-road.

The Professional Calendar;

OR, WEEKLY REGISTER

FOR GENTLEMEN REQUIRING ASSISTANTS, AND FOR ASSISTANTS SEEKING APPOINTMENTS.

EACH Announcement of Three Lines—about thirty words—will be charged at the nominal rate of ONE SHILLING *per insertion* (6d. *each additional line*).

As this Calendar *will be for the use of the Readers of this Journal, and from which no pecuniary advantage will accrue to the Proprietor, each Advertisement* MUST *be accompanied by Postage Stamps (Penny) in pre-payment.*

Wanted, a Locum Tenens, to take Charge of a Town Practice during the absence of the principal. He must be a person of experience, and have unexceptionable references and testimonials.—Address, Medicus, 23 St. George's Road, S.E.

Qualified Assistant Wanted (in-doors), in a General Practice ten miles from London. Would suit a Guy's man wishing to attend London two or three times a week.—Address, Surgeon, care of Messrs. Kirkland, 23 Salisbury Street, Strand, W.C.

Assistant Wanted, sine diploma, to dispense, keep the books, visit, and occasionally attend Midwifery. Must be strictly sober.—Address, enclosing carte (to be returned), stating salary required, age, references, &c., Dr. Roberts, Upperthorpe, Sheffield.

Wanted, a Situation as Assistant, by a Gentleman aged 21, who has attended all his lectures, and has the Rotunda Midwifery diploma. Salary no great object.—Address, G. M., Dr. Ellis, Rychill, Newcastle-on-Tyne.

Wanted, by a Gentleman aged 28, married, a Situation as Out-door Assistant.—Address, stating salary, &c., to H. P., Post-office, Lutterworth, Leicestershire.

Wanted, a Gentleman, doubly qualified, for Country Practice, out-door.—Apply to R., care of Gale and Co., 15 Bouverie Street, Fleet Street, E.C.

Wanted, a Situation as Dispenser and Book-keeper to a Medical man. Has had three years' experience both in Surgery and Dispensing.—J. C., 66 George Street, Euston Road.

Wanted, an Out-door Assistant, to visit, dispense, and attend Midwifery. A knowledge of Welsh necessary.—Richard Thomas, Surgeon, Llanelly, Carmarthenshire.

Wanted, by a Gentleman, unqualified, a Situation as ASSISTANT. Is a good Accoucheur, and accustomed to Club and Private practice.—E. B. S., 371 Edgware Road, London.

Wanted, an Engagement as Assistant, to dispense, visit, and attend Midwifery. Has finished Medical curriculum. Unexceptionable references.—A. Z., Post-office, St. Alban's, Herts.

Wanted, an In-door Assistant, to visit, dispense, and attend Midwifery.—Address, enclosing carte, giving all particulars and references, to Dr. Thomas, Church Street, Sheffield.

Wanted, an Assistant, fully qualified, to visit, dispense, and keep books. State age, salary, and reference.—F. J. S. Stafford, Surgeon, Market Place, Great Yarmouth.

Wanted, an Assistantship, to visit, dispense, and attend Midwifery. First-class references. Age 25.—Address, H., Dr. Johnson's, Whitwick, Leicestershire.

McDOUGALLS' MEDICAL CARBOLIC SOAP.

An Antiseptic and Healing Detergent.

FREE FROM ANY INJURIOUS INGREDIENT.

Invaluable as a Wash or Lotion for Cutaneous Affections, Sores or Wounds, and as an Antiseptic and Disinfecting Agent for Internal or External application.

It is a neutral Soap carefully prepared, and provides the best means of conveying Carbolic Acid to the Skin. Its use is pleasant and refreshing, renders the Skin soft and smooth, and is quite harmless even to the tender flesh of Infants. The Antiseptic properties of Carbolic Acid are in no case more apparent than when applied as compounded in this Soap, and are so beneficial in cases of Cutaneous Affections that the use of this Soap is Recommended by many leading members of the Medical Profession. Manufactured only by

McDOUGALL BROTHERS,

London: 11 Arthur Street West, London Bridge, E.C. Manchester: Port Street.

DINNEFORD'S FLUID MAGNESIA

Perfect in purity and strength.

"The Fluid Magnesia I obtained from you corresponds precisely with that of the 'British Pharmacopœia,' 1867, and is what the preparation should be."—Professor Redwood.

Sold in Gallon and Half-Gallon Jars for the use of the Profession *only* by all Wholesale Druggists, and by the Manufacturers,

DINNEFORD & CO., PHARMACEUTICAL CHEMISTS,

172, New Bond street, London.

NITROUS OXIDE, & OXYGEN GAS

FOR INHALATION.

BARTH'S APPARATUS is used at several Metropolitan Hospitals.

A Pamphlet on either of the above with Price List, &c., sent free on application to

LONDON: GEORGE BARTH AND COMPANY,

26 DUKE STREET, BLOOMSBURY, W.C.

The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JULY 27, 1870.

CONTENTS.

Lecture.

CLINICAL LECTURE ON CASES OF PULMONARY GANGRENE.

By C. Handfield Jones, M.B., Cantab., F.R.S.,
Physician to St. Mary's Hospital.

Case I.—J. S——, æt. 40, gardener, admitted February 28th, 1868. Had always been a weakly man, but continued at his employment until September, 1867, when he had a slight attack of diphtheria. At the same time two of his children died with the same disease, and two other members of his family were also attacked. Two years ago he had sunstroke, was insensible for some time, and ever since his memory has been bad, and he has had occipital pain. His residence is said to have been badly drained—the rooms offensive. His symptoms at first were those of impaired sensory and motor power, all his four limbs at one time being paralysed well nigh completely. This paralysis had quite disappeared by March 23rd, and even some days earlier. His pulse on admission was 74; his urine clear, palish, sp. g. 10·24, non-albuminous; his heart and breath sounds normal.

March 10th.—His pulse was 110, and his temperature 102·5°; he had thirst. On the 12th his temperature was 104°; his urine turbid and highly alkaline. On the 16th his tongue was white, with a median brownish dry streak; his temperature was 103·3; pulse 100; weak; some red papular spots, not however characteristically typhoidal, had appeared on his abdomen; and there was some tenderness at the right iliac fossa and side of abdomen. The bowels were very constipated. He complained also of pain in the right side on deep inspiration; at the right base and side the breath sound was weak, and there was some obscure râle: there was no dulness in either back, and the breathing was normal in both upper parts. Delirium at night had occurred, but the paralysis was much less. 18th. Tongue much more brown and dry; pulse 130, weak; temperature 104·4; several pretty distinct typhoid spots on back, and some more doubtful ones on abdomen; sweats copiously. 20th. Brought up at eleven p.m. last night and several times since a good deal of very offensive darkish muco-purulent matter. Some degree of dulness at mid part of right back, and tolerably well marked bronchial breathing, with absence of vesicular, in most of this back; in the left the resonance and breathing were good; urine loaded with lithates; temperature 103·3°. On the 21st the urinary sediment was mainly dissolved by heat (lithates), but contained also numerous prisms of triple phosphate, as well as small spherules. On the 23rd the urine effervesced copiously with H. Cl., and deposited a copious sediment of small imperfect phosphate prisms. 24th. Cough hard and straining; sputa muco-purulent and extremely offensive. 25th. In lower part of right back the breathing is null, or nearly so; only a little creaking sound is to be heard; higher up some breathing is audible. He gradually declined, and died April 18th; the expectoration remained offensive, though not constantly so, to the last. On April 13th it contained a notable amount of blood; at the same date I noted that there was clear (tympanitic?) percussion sound at the lower part of the right back, but the air entered feebly and imperfectly with harsh tube sound; vesicular breathing was heard distinctly nearly as far as the middle of the back. In the record of the *autopsy* it is stated that all the abdominal organs and the heart were found healthy, but unfortunately the intestines were not opened. The left lung was engorged, œdematous, and very much softened, quite in an early stage of pneumonia; it was large and bulky. The upper lobe of the right lung was inflamed and condensed to some extent; the lower was completely excavated by a foul gangrenous cavity, containing extremely offensive greyish matter.

The treatment employed was mainly supporting and stimulating, consisting of potass. iodid., ammon. carb., quinine in gr. v doses *ter die*, bark with potass. chloras, nitric acid either alone or with quinine, and creasote in pills. The latter seemed to be of some real efficacy in diminishing the fœtor; the patient himself asked to have it again for this purpose when it was discontinued on one

occasion. Carbolic acid was also used in the way of inhalation, but did not produce any noteworthy effect. Perhaps it would have done better in the form of spray.

Case II.—C. W——, æt. 44, labourer, admitted February 15th, 1870. Ill one month. "The stench from his breath has been fearful." Last two years has had winter cough. Has much cough and expectoration; has been expectorating stuff like matter, and bloody. Can't lie down in bed. At present is constantly coughing and expectorating nearly clear mucus; pulse quick and weak; the next day it was 96, and excessively weak and small; temperature, 102·7. The expectoration was very copious, discoloured, mucopurulent and very offensive. There was comparative dulness in the right front, and almost complete absence of breath sound; two days later there was completely cavernous breathing. In the right back the breathing was very weak, and attended with obscure râle, but there was no very marked dulness. On the left side the breathing and resonance were fairly good. He was ordered to inhale steam with turpentine vapour, to have a turpentine stupe to the back, and to take creasote ℥i. + acidi nitrici ℥. iij + infus. gent. Co. ℥i + liq. opii sed. ℥. viij *quater die.*; simple diet; beef-tea; port wine 8oz. 21st. Is said to have spit up a notable amount of blood during the night; the expectoration seen consisted of thick, heavy muco pus; pulse 93, of good force; temperature 102·2. The fœtor of his breath was so great that he had been removed soon after his admission to a separate ward. He was ordered chlorine inhalation, and tannin gr. v, and bals. canad. gr. ij in pil. ij *quater die*, continuing the nitric acid and creasote. On 26th, as he complained of having no rest from cough, he was injected subcutaneously with liq. opii, and slept better the following night. On 28th, the left lung continued to act well; the right front was woodily resonant at its upper part; dull at its lower; breathing in this front was almost null, only some tubular sound could be heard; in the right back there was some imperfect breathing at the upper part, but all the lower half was dull and nearly silent.

March 7th.—Left back continues resonant, but the breathing is very defective, and is replaced by mucous râle at the lower third. The right back is dull throughout, and distinct tubular breathing is heard in all its extent; pulse 96, of good size, and volume; urine loaded with lithates. On 16th it was free from albumen, sp. gr. 101·8. The fœtor by this time had almost quite disappeared; I scarcely perceived any. March 19th. Pulse 87, quiet, weak; expectoration much diminished; free from fœtor; skin cool. Breathing in right back consists of harsh short inspiratory and very harsh loud prolonged expiratory tube sound. In the right front there is woody percussion, cavernous breathing, and pectoriloquy. On April 5th he was in much the same state; pulse 105, soft; temperature 102·5°; he took a meat diet well as he had done for some time. The tannin pills and creasote mixture were replaced by citrate of iron and quinine. On 9th the fœtor which had quite, or almost quite, ceased was again very bad, and his cough was severe. The creasote mixture was ordered again; and on 11th the fœtor was much lessened; he was up and dressed, and proposed leaving the hospital. On the night of the 12th he was very restless, and in the morning the house surgeon noticed how remarkably he was changed; he was quite blue in the face; in the evening he died.

Post-mortem.—Left lung fairly healthy; right lung excavated at upper part by a large irregular cavity, with blackish red walls; the fissure between the upper and middle lobes was occupied by a considerable layer of fibroid induration, a-quarter or a-third of an inch thick. There was a large quantity of fœtid sero-purulent fluid in the pleural cavity at the lower part; the serous membrane was a good deal thickened. The arch of the aorta was much dilated so as to constitute a true aneurism. There were large fibrinous coagula in the aorta and in the right auricle and ventricle; the auricle was filled with decolorised clot, and the ventricle contained a large similar mass. The coagulum in the aorta was very large and solid, but after an inch or two it changed into black clot. One or more of the cervical veins contained at their lower part a completely decolorised coagulum. The brain was small, weighed only 40 ozs. The abdominal organs were fairly healthy, and so I am satisfied were the heart's tissue and valves.

Case III.—G. F——, æt. 55, coachman, admitted outpatient Aug. 15th. He stated that he had been ill seven days; his appetite was lost, his speech was feeble; he had a bad cough, was very weak; his tongue was thickly coated, bowels open, but no diarrhœa; his pulse was very feeble. A dose of calomel gr. ij. + opii, gr. ¼ was ordered for three nights, and acidi nitrici ℥iij. *ter die.* On 22nd he felt very sinking, and his cough was bad and his tongue foul. He was ordered mixt. quinæ ℥i. + strychniæ gr. 1-20th *ter die.* Sept. 1st, he was in quite the same state, very weak. Tongue had got clean, however. The urine was clear, very acid, not albuminous; smelt most abominably of rotten cabbage. His breath had the same putrid odour. No appetite. His cough was rather frequent and caused him to vomit his food. Some sputa I saw consisted of dirty grey mucus, devoid of the putrid odour of the breath and urine. Auscultation detected nothing abnormal in the lungs. The abdominal organs appeared normal. I ordered liq. sodæ chlorinat ℥xx. + aq. ℥i. *ter die.* Sept. 5th, he was very depressed, his breath fœtid as before, his expectoration copious, of a dirty yellow grey. Good breathing was heard in right back, diffused râles in left, together with good breath sound. In the left upper front the breath sound was pretty full, but in the middle and lower it was very weak and imperfect, and attended with crepitations. In the right front the breathing was more free, but crepitations were also heard. He had not the least pain in the chest. 6th. Skin cool, pulse feeble. Brandy four ounces; chlorine inhalation. Morph. acet. gr. ½ o. n. On 10th comparative dulness was observed in the lower left back; the breathing in this part was weak and somewhat tubular. Fine crepitation was heard all through the left front, and towards the side. In both fronts the percussion note was woody; there was tolerably good breathing, with expiratory tube sound in the right front. The fœtor and sputa were as before.

13th.—Pulse exceedingly feeble; skin cold; sputa and fœtor same. Brandy six ounces. He had been taking for four days nitric acid and cascarilla, with pills of tannin and canada balsam; these were now exchanged for ammonia carbon. 16th. Air enters well into right lung posteriorly, but with some crepitation. Air enters pretty well into lower posterior left lung, but at the upper part the breathing is null, and at the middle is replaced very much by crepitations. Air enters the right lung freely in front, but the breath sound is rather coarse. In left front the breathing is very weak and of tubular quality; the percussion note is not dull but woody, and the same in both backs. Sputa and fœtor same. Urine not albuminous. No notable dyspnœa now, or at any former time. Port 10 ozs., tinct. cinchon. ℥i. c mist. He died on 18th.

Post-mortem on 19th.—Right lung emphysematous, inflamed to some extent posteriorly, and showing some small patches of pale exudation. Left lung in a state of grey hepatisation throughout the upper lobe; the lower lobe highly inflamed at the posterior part. In the upper lobe was a very large gangrenous cavity as big as two fists, containing little but blackish loosely floating shreddy pulmonary tissue in a state of slough. The large gangrenous cavity in the left upper lobe was separated by a very thin layer of tissue from the pleura which adhered pretty firmly to the costal pleura over a large extent. In the right lung, at the upper edge of the middle lobe, there was a small round cavity as large as a marble in contact by its periphery with the pleura, quite full of a dark matter. Under the microscope the contents of this cavity showed ramifying vessels, or rather their *débris* mingled with abundant dark-red pigment, and numerous fatty-looking granules or small masses. The lung around this cavity

was condensed for a very limited extent. The heart and all the other organs were normal. In the right apex there were some remnants of cretaceous tubercle.

Case IV.—B. F——, æt. 40, admitted September 14th, 1860. Ill fourteen days, suffering from cough and pain in right side of chest. Her breath, when coughing, is exceedingly offensive, having quite the odour of gangrenous lung, but not so at other times. Breathing rather coarse and harsh, but air enters freely into both lungs. Sputa copious, not offensive. Urine without any peculiar offensive smell. Pulse, normal; strength, good. Mixt. Scill. Co. + spt. æth. chl. ℥x. *quatdr. die.* Creasoti ℥i. in pil. 3 tiis horis. Liq. chlorinii *pro hinalat.* Oct. 6th. She spit up some bloody matter. On 8th there was a considerable amount of dirty grey-looking muco-watery sputa with a decided tinge of blood. In the right front and back the breathing was imperfect and attended with râles, and the existence of a cavity in the upper part of this lung appeared tolerably certain. No marked pyragia. Has bottled stout. 11th. Continues to spit up much mucomatery sputa, tinged with blood; has copious night sweats. 15th. Sputa tenacious, of a dirty greyish-brown colour, verging upon red. Cough distressing. Crepitations through all right lung in front and behind. In left posterior base there is breathing of tolerable quality, but higher up it becomes very weak and bronchial, and attended with râle. In left front the breathing is good. The sputa consist of mucous corpuscles, with numerous masses of pigment here and there. One of my colleagues found an object which he considered to be lung tissue. On 20th the sputa were much improved in appearance, more simply mucous, not blood-tinged, and in smaller quantity. She felt much better. She left the hospital at her own request about the beginning of November. Her improvement coincided with the administration of tinct. ferri muriat., ℥x. + spt. orth. chl. ℥xv. 4 tis h. The fœtor of the breath and urine seems to have gradually subsided, though my notes are not precise on this point.

In none of these cases does any evident cause appear to account satisfactorily for the gangrene. In the first, indeed, there was great impairment of nervous power, the result of the sunstroke and of the diphtheria, but in both these pathemata pulmonary gangrene is a very rare occurrence. Yet it should be mentioned, that, according to Dr. Walshe, gangrene of the lungs is not unfrequently met with in cerebral disease, and he thinks its occurrence "fairly explicable by deficient or perverted nervous influence." Griesinger remarks that gangrene of the lungs is especially frequent in cases of melancholia, where food is refused, though it is not confined to such cases. As it occurs also in stricture of the œsophagus it seems most probable that it is the result of general inanition and exhaustion, rather than of failure of nervous power. That the gangrene depended on embolism or thrombosis does not seem to me very probable, because there was no condition discoverable which would have caused fibrinous particles to have been floating in the blood-stream. Moreover, the communication of the pulmonary plexuses is so free, that blocking of one branch would be easily compensated by the flow from the adjoining vessels. It may also be remarked that the rarity of pulmonary gangrene in cases of endocarditis, and its comparative frequency in typhus fever, are opposed to the view in question. The only point in the treatment worth notice is the action of creosote, which certainly did seem to have the effect, given internally, of removing the fœtor of the breath, and probably, therefore, modified beneficially the morbid process in the lung. The fatal termination of the second case I cannot but think was owing to the formation of fibrinous deposits during life, although a very good authority who was present at the autopsy maintains that they were merely *post-mortem* productions. However, the size of the fibrinous coagula in the right cavities of the heart and in the aorta makes it, to my thinking, utterly improbable that they could have been formed by the mere subsidence of the red particles into the veins, as the volume of blood in these channels and cavities could not have yielded a sufficient amount of fibrine. Moreover, the peculiar symptoms preceding dissolution are exactly accounted for by the view of *ante-mortem* deposits, and quite fail to find an adequate explanation otherwise, as the patient's condition had certainly very materially improved since his admission, and up to within a day or two of his death the improvement was well maintained. Neither did the autopsy disclose any other recent mischief than the fibrinous deposition to account for the fatal event. I believe I have witnessed the same occurrence in two or three instances the last few months, and I think Dr. Richardson's statements in this matter are fully borne out by experience. In the third case there seems to me much reason to believe that the gangrene was primary, and was not the result of the inflammation which was found at the autopsy, and whose physical signs were not discoverable at the outset; when, however, the prostration and the fœtor left little doubt that gangrene was actually in progress. The small round gangrenous cavity in the right lung was clearly in an earlier stage of the process than the large one in the left, and its small size, perfect definition, and spherical shape, seem to me to make it difficult to understand how it could be the result of obstruction of an artery. This would, probably, produce a gangrenous patch of conoidal form. The peculiar fœtor of the urine was remarkable, and must be attributed, I suppose, to the excretion of putrid matter absorbed from the altered lung into the blood. It would indicate, therefore, a more grave condition of blood-poisoning than exists in cases where such fœtor is absent.

In the fourth case also the gangrene seemed to be primary, and to have preceded the occurrence of lung inflammation. The presence of fœtor only during coughing is noteworthy; it probably depends on obstruction of the bronchi leading to the gangrenous part, and on the removal of this obstruction by forcible expirations. In this case, as in I. and II., blood was present in the expectoration to some amount at one time or other. The same occurred also in another instance where the gangrene was succeeded by cirrhosis. I have thus met with hæmoptysis in four out of five cases. Dr. Walshe mentions that the bleeding has occasionally been so profuse as to cause sudden death.

As we have so little control over pulmonary gangrene when it is once established, and as it seems not unfrequently to commence in a gradual manner, it is evident that to be on the watch is of main importance, and that whenever we have to do with cases where the nervous system is gravely involved, or the general power seriously impaired, we should endeavour to guard against its occurrence by using all the means in our power that may obviate exhaustion.

Hospital Reports.

MERCER'S HOSPITAL.

Strangulated hernia in a child nine months old.—Reduction under chloroform.

By Mr. Morgan, F.R.C.S.I.,
Surgeon to the Hospital, &c.

A child of nine months old was brought to me by an intelligent and anxious mother, who stated that the rupture (a right inguinal) had existed for the last three months; that it used occasionally to appear pretty large, and be easily reduced. However, for the last two days it had got down and she now found it immoveable; the child had suffered great pain, and was constantly crying; the belly was swollen, and she had given castor oil freely without effect, as there had been no motion for nearly three days.

On examination, the child was pale and weak, with an extremely small and rapid pulse, and was constantly

making some effort at vomiting, and was verging on collapse; the tumour was tense and resisting. I tried by careful manipulation to reduce the intestine, but, with such moderate force as was considered judicious, no progress was made. I now put the child cautiously under the influence of chloroform, when in about five minutes I effected reduction—the symptoms showing marked alleviation, almost directly. I saw the child next morning, and it was, as the mother remarked, "as well as ever." The bowels had meanwhile been well freed.

The anatomical condition and greater muscularity of the abdominal rings in so young a subject no doubt facilitated the reduction, as being so much more capable of relaxation under the influence of chloroform.

METROPOLITAN FREE HOSPITAL.

Dr. Charles Drysdale speaks very favourably of the use of faradisation and the continuous galvanic current in the treatment of many diseased conditions. In lumbago he has found faradisation by far the best of all treatments. The battery used by him at this hospital—galvano electric—admits of the rapid application by means of wet sponges of the galvanic current to the integument over the dorsal and lumbar muscles. The use of faradisation in cases of stiff joints after rheumatism is much praised by Dr. Drysdale, as also in cases of infantile paralysis. He has treated some cases of amenorrhœa successfully by means of faradisation, one pole being placed over the pubis, and the other either on the cervix uteri or on the back. Involuntary nocturnal emissions are well treated by faradisation of the perineal muscles. Neuralgia and paralysis are better treated by gentle continuous currents, and, when nothing better can be obtained, the bands sold by some galvanists often will cure cases of sciatica, or other neuralgic affections.

UNIVERSITY COLLEGE HOSPITAL.

In a recent visit to University College Hospital we found that Dr. Ringer was making use of faradisation in cases of lumbago and other painful muscular affections apparently with success. He was also in favour of the application of the process of Dr. Richardson for the relief of certain frontal headaches. To this end, Dr. Ringer used the ether spray for some time to the skin of the forehead, until it became frozen in several parts. In the operating theatre we witnessed the extraction of some of the *débris* of a calculus by Mr. Erichsen from the bladder of a male patient of some sixty years of age. Also an attempt which was made by Mr. Berkeley Hill to straighten the foot in a most formidable looking case of contraction of the plantar fascia and tendo achilles, &c., which had caused the pat ent for many years to walk on the back of the foot. Mr. Hill divided the plantar fascia subcutaneously, intending subsequently to do the same with the flexor tendons. The wards of University College are now admirably managed by the nursing sisters, although the dress they wear is rather too suggestive of asceticism for our humble taste.

ARMY HOSPITALS.

Case of Obstruction of the Intestines treated by Opium.

By Staff Assistant-Surgeon Scanlan, M.B.

Private R.E., of the 1st Battalion, 4th (King's Own) Royal Regiment, was admitted into hospital on the 19th May, 1869, complaining of pain in the abdomen and constipation of the bowels. The patient is 36 years of age, and has had 13 years and 7 months' service.

The pain was first felt three days before admission, and came on suddenly after dinner. During the two following days he worked hard, as the regiment were removing to other barracks, and he was employed in carrying baggage. When admitted he was slightly feverish, and his bowels had not been properly moved since the time he felt the pain, three days previous to admission. On the 20th May he passed a little at stool, and first noticed that the abdomen was swollen. The pain continued, but it became of a dull aching character, though at first it was intense. Castor oil and then croton oil were given at first, without moving the bowels, and fomentations were applied to the abdomen.

On the 22nd May, three days after admission, the long tube of the stomach-pump was passed into the large intestine, and a large quantity of warm water and castor oil was thrown up; this was retained for some time, and then passed out, without bringing away any fæcal matter or giving permanent relief. The enema was repeated on the evening of the same day with a like result.

On the 23rd May a cantharidis plaister, four inches by five, was placed on the epigastrium where the pain was felt most severely, and two grains of calomel were given every two hours. Patient was placed on low diet when admitted, and six ounces of wine were ordered daily up to the 23rd.

On the 24th May patient was much weaker, and had little rest the night previous. He had not been able to take any food since the day before admission, with the exception of a little beef tea every day, and he was ordered four ounces of brandy instead of the port wine which he had before. The day previous to this he vomited a quantity of green fluid, and felt for a time much relieved by it, but on this day, although he felt a constant inclination to vomit, he was unable to do so. The urine was high coloured and scanty, and, although he felt a constant thirst, he could not drink much, as he would feel painfully distended. The pulse was normal, tongue very foul, and countenance anxious. The fomentations were continued, and the calomel was given, with the addition of half grain doses of opium every two hours.

On the 25th May patient felt easier, but nothing had been passed per anum. The abdomen was enormously distended, though the pain was less severe, and he was much troubled with hiccough. There was no fever, and the pulse was not rapid. The calomel, opium and fomentations were continued, and the long tube of the stomach-pump was again introduced at his own request, as he felt an inclination to go to stool; but, although a large quantity of warm water, oil and soap was thrown up, and retained for quarter of an hour, no fæcal matter passed out.

On the 26th May he was ordered half a grain of opium every two hours, and beef tea enemata, as he was much reduced through want of nourishment, and could not take it into his stomach. He slept none on the previous night, and was evidently becoming much weaker. On three occasions he passed a small quantity of the secretion of the large intestine.

On the 27th May galvanism was applied to the abdomen, one pole being placed on the lower dorsal vetebra, and the other moved gently over the whole surface of the abdomen. He was then placed in a bath and a stream of cold water was poured from a height down his back, but all these measures failed to relieve the distended state of the intestines. The brandy was increased to eight ounces a day, and the opium continued.

On the 28th May there was no improvement. The beef tea enemata were continued and retained. The pain was still present chiefly in the umbilical region, but the abdomen was not more distended than before. Towards the evening the pain became worse, and he was ordered one grain of opium every hour until he was relieved, and the blistered surface was covered with an extract of aloes. In the morning he passed a great quantity of wind, and felt relieved for a time.

On the 30th May at 3.30 a.m. patient was raised up to the stool and passed about a pint of dark grumous-looking fluid of offensive odour. He had previously been in great pain, and it was at once relieved. At 5 a.m. he passed about

a quart of the same dark matter. The swelling of the abdomen became less, and the pain vanished entirely. During the day he went several times to stool, and the evacuations became gradually more natural and devoid of offensive odour. In the evening he complained of griping pains, which were relieved by hot fomentations.

31*st May.*—During the night he got up to stool several times, and passed altogether about a gallon of light brown semi-fluid matter, with the natural odour of fæces. He then slept well, and felt much relieved in the morning. The opium was discontinued on the 30th.

Yesterday and to-day he has taken spoon diet, with two pots of extract of meat and two eggs each day, and the brandy has been continued.

1*st June.*—There is now no tenderness in the abdomen, though it is still flatulent. He now takes his food, and feels hungry. The tongue is becoming clean, and the countenance is clearer. He went to stool twice to-day. Is put upon low diet.

2*nd June.*—Complained of griping pains in bowels and over liver when he takes a long breath. They were relieved by hot fomentations.

Patient continued to improve, and was discharged to duty on the 19th of June perfectly recovered, though feeling rather weak. He afterwards went on sick furlough for six weeks.

Recapitulation.—The disease began suddenly on the 16th May, with an intense pain in abdomen while patient was at stool, and, although he had several slight motions up to the 20th, the bowels were not moved freely until the morning of the 30th May, an interval of 14 days, and for 10 days nothing whatever passed from the bowels, except the secretation of the intestines.

Literature.

ETUDE SUR LES NEVRALGIES REFLEXES SYMPTOMATIQUES DE L'ORCHI-EPIDIDYMITIS BLENORRHAGIQUE.*

This is a most painstaking and interesting clinical work, written by a gentleman whose position as Physician to the Hôpital du Midi at Paris has placed him in one of the best spots in Europe for calmly studying the diseases accompanying syphilis and gonorrhœa. Dr. Charles Mauriac has already written several interesting treatises; among others, too, a translation of Dr. West's admirable treatise on "Diseases of Women." The conclusions come to by our author will, perhaps, explain better than any other portion of his work, we can cite, the tenour of his opinions. He says: —

1. There exists in blenorrhagic orchi-epididymitis two kinds of pains—*a*, local and direct pains, which are connected with the inflammatory process of the epididymis and of the testicle; *b*, reflex pains, sympathetic or distant, which may be called reflex neuralgias.

2. The reflex neuralgic pains are dull and lancinating, continuous and paroxysmal; they manifest themselves under the form of attacks which return irregularly. Far from being excited and exasperated by the touch, as inflammatory pains are, they are, on the contrary, for the most part calmed by pressure and spontaneously produced. They change about in their place, and in their mobility occupy successively, or simultaneously, not only different parts of the same nerve, but one or several branches of nerves belonging to the same plexus or two different plexuses.

3. They do not present in their progress the regularity of the organic process which has given birth to them. It would seem that they owe to a sort of autonomy they have acquired, in spite of their primitive subordination to a fixed lesion, the power of appearing in their own fashion; that is, irregularly. The morbid impression which gives rise to them commences in the testicle and ends in the spinal cord. This impression is perceived or not perceived at the point from which it sets out. When it comes to the nerve centres, it modifies pathologically the functional working of the nerve cells. Thence result in the course of the nerves of sensation, which are in communication with these nerve cells, painful sensations which are produced in virtue of the law of eccentricity of sensitive phenomena, or of peripherism of sensations.

The laws of motor reflexion laid down by Pfluger are not rigorously applicable to sensitive reflexion. Thus the painful irradiation reflected by the nerve centres may be produced below the point of incidence of the mitral morbid impression; in general it is diffused without any rule. In orchi-epididymitis with reflex neuralgias, the reflexion may be carried by the side of the viscera by means of the spinal cord of ganglia of the sympathetic. The intensity of the pain in such neuralgias has no relation to the intensity of the local pain. When the reflex irradiation aroused by the morbid impression, caused by the diseased condition of the testicle, acts on the sympathetic plexus, there may arise a collection of phenomena much more complicated than simple pain, such as peristaltic movements and antiperistaltic movements of the digestive tube, or gastro hepatitis and feeling of great cold or heat. These neuralgias are usually unilateral. Pain in the spinal column is the most frequent of the reflex irradiations of orchi-epididymitis, and has two foci—one renal, the other sacro-sciatic. Sometimes there are pains in the loins, hypogastrium, or inguinal region; sometimes along the lower limbs, crural, or sciatic. The inflammation of the testicle, or its annexed organs, has, according to Dr. Mauriac, a remarkable property in diminishing the quantity of the red blood globules very rapidly. We advise any of our readers who are interested in reading a careful collection of clinical data, to read Dr. Mauriac's work, as well as the notes to his translation of Dr. West.

* Etude sur les Nevralgies Réflexes Symptomatiques de L'orchi-Epididymitis Blenorrhagique. Par Charles Mauriac, Médecine de l'Hôpital du Midi. Paris: F. Savy, 24, Rue Hautefeuille. 1870. Pp. 111.

LIFE AND THE EQUIVALENCE OF FORCE.*

The author tells us that, on making enquiry into the question of the doctrine of the conservation of force, he could find no compendious and complete history and exposition of the doctrine in the English language adapted to the general run of medical men. Carpenter's seventh edition has a chapter on the balance of the vital economy, in which it is taken for granted that the reader understands the principle. This is taking a good deal for granted. Heat and motion are interchangeable. "By the splendid hypothesis of Meyer (says the author) engrafted on that of La Place, the contraction of the nebular mass of the matter of our solar system is exhibited as a sufficient cause of the original heat of the sun. The fall of this vast mass of matter through such immense distances is competent, according to the calculations of Helmholz, to generate in the sun a heat of 22,000,000 degrees, cent., the far greater portion of which must have been dissipated long before the earth assumed its present state. For it is also a part of the doctrine in question that all forms of force or energy are mutually convertible, but, practically, the final result of all such transformations is into heat or light. These, as is well known, are perpetually radiating into the surrounding medium; and hence, with the exception of such portions as are absorbed by plants and chemical action, the tendency is finally to be dissipated into space. This dissipation of the sun's energy is perpetually going on at an enormous rate, of which we can form some conception by the fact that

* Life and the Equivalence of Force. By J. Drysdale, M.D. London: Turner and Co., Fleet Street. Pp. 74.

the total amount of it intercepted by the earth is equal to only the 2,300,000th part of the whole. Ultimately, a time must arrive when, by the action of the natural forces resulting in the continual dissipation of energy, and the exhaustion of the meteoric system, the final extinction of life, heat and light in our system must ensue, realising the vision of the poet—

'The bright sun was extinguished, and the stars
Did wander darkling in the eternal space.'"

The author seems to think that the discovery of the law of the equivalence of force is only second to that of Newton or Copernicus. "The glory of its discovery belongs to Robert Meyer, of Heilbronn, and Prescott Joule, of Manchester, who arrived at it simultaneously and independently of each other." In 1850, Meyer mentioned how that, in the year 1840, he had been surgeon to a vessel which sailed to Batavia, where an inflammatory disease of the lungs broke out among the crew. The young surgeon bled copiously, and was struck by the bright colour of the blood which issued from the vein in newly-arrived Europeans. The heat generated by a living body through mechanical processes must stand in an immutable quantitative relation to the work expended thereon, and from this it follows that an immutable quantitative relation between heat and work is a postulate of the physiological theory of heat. Reasoning thus, Meyer was driven to investigate what was the mechanical equivalent of heat. By means of various mechanical experiments it has been found that one unit of heat is equal to 772 lbs. raised one foot high.

In 1844, the now illustrious physicist, Joule, who, independently, was working in the same direction as that of Meyer, repeated some of his experiments. According to the dynamic theory of heat, which is now universally adopted, it is supposed to consist in a peculiar oscillatory or vibratory motion of the particles of matter. This motion may be communicated directly from one set of particles to another, which is called conduction; or it may be transferred by undulations in the aether, or medium, which pervades not only the whole interstellar space, but the interstices of ordinary matter: this is termed radiation. As a rule, all the heat communicated to solid and liquid bodies, which is consumed in anterior work, is given up again on cooling by a spontaneous process.

"Meyer made experiments on four pulping cylinders in a paper mill. In each cylinder was contained about eighty pounds of paper pulp and about 1,200 pounds of water. The temperature of the pulp rose steadily from the time of setting in. The surrounding temperature showed 15°, cent.; in thirty-two to forty minutes the heat of the pulp rose from 14° to 16°. The highest temperature observed, which was uniformly maintained for several hours before drawing off, amounted in one cylinder to 30°. If we now reckon that, by one horse-power, about 27,000 pounds are raised one foot high in a minute, then the heating of 1,280 pounds of water 1° in sixteen minutes must be equivalent to 3·16 horse powers, which agrees with sufficient accuracy with the computation of the manufacturer, that a total of about five-horse powers is required for driving one cylinder. How does the mechanical effect yielded by the five horses vanish into nothing in the machine? The fact speaks—*it becomes heat!*"

Such are a few quotations from this very interesting work. Written, as is, not by a professed physicist, but by a practitioner of the healing art, it betokens, in the author, a rare combination of love for abstract science with practical skill. We heartily wish the pamphlet all success, and that it may advance the author's name as a writer on the sciences bearing on medical science.

The Speaker of the House of Commons has given a donation of £100 to the funds of University College Hospital, and £100 to Westminster Hospital. The Mercers' Company have also presented £100 to the latter Institution.

Summary of Science.

By C. R. C. TICHBORNE, F.C.S., M.R.I.A., etc.

On an insoluble dextrine.

M. Musculus has prepared the above substance by heating starch in crystallizable acetic acid. This dextrine seems to be composed of granules of starch, in which, whilst the granules are unbroken, the substance in the interior is changed into dextrine (*est composée de fragments de grains de fécule, dont l'organisation s'est conservée malgré la modification climiquz qu'ils ont subie*). Other methods are described in his papers, vide *Journal de Pharmacie* Juin, which give slightly different dextrines.

The author says that on examining the action of these dextrines upon polarised light they are found to agree amongst themselves as regards their power of rotating. Their specific power of rotating is $[a]=+208°$, which is notably superior to that of ordinary dextrine, which is $[a]=+138°$.

Researches upon lichens.

Dr. Stenhouse (still following up this favourite line of research) we find experimenting with two lichens—*Cladonia rangiferina* and *Usnea barbata*.

The usnic acid is obtained from the last named lichen by macerating it with carbonate of sodium and precipitating with hydrochloric acid. Usnic acid is easily obtained pure by taking advantage of the peculiar property which the acid possesses of forming an insoluble calcium salt, when it is boiled with lime.

The composition of the acid is $C_{18}H_{18}O_7$.

Usnate of sodium crystallizes in pale yellow silky needles, very insoluble in cold water, but more so in spirit. It is decomposed by passing a current of carbonic anhydride through its aqueous solution, and the acid is entirely precipitated.

The *Usnate of calcium* is formed when usnic acid is moistened with spirit, and then, rubbed up with milk of lime, it yields a lemon-coloured solution, which, when heated, becomes turbid, and, after boiling, deposits an insoluble calcium compound in small yellow rhomboidal crystals of uncertain composition. The formation of this insoluble calcium salt is very characteristic of usnic acid, and is an excellent test of its presence. Carbonic anhydride entirely decomposes it; usnic acid appears, therefore, to be a very feeble acid. An attempt was made to form the ethylic usnate, but without success; in this case usnate of silver was treated with iodide of ethyl.

The author in the same paper describes evernic acid and its bromine derivative Tetrabrom-evernic acid ($C_{17}H_{12}Br_4O_7$)—crystallizable compounds obtained from the *Everna prunastri*, also the lichen acid from *Cladonia rangiferina*, having very much the same properties as usnic acid, and agreeing in composition, but having a different fusing point. This "cladonic acid," or B-usnic acid, melts at 175° C; ordinary usnic acid melts at 203° C.

The bromine compounds are formed in the following manner:—Evernic acid was treated in the cold with dry bromine, the acid being finely powdered; the product was again finely powdered and re-treated with bromine, and after allowing it to stand some time to allow the excess of bromine to volatilize, the compound was washed with bisulphide of carbon. Two or three crystallizations from boiling spirits rendered it quite pure.

Patent for heating stoneware vessels to a high temperature.

In manufacturing on the large scale, stoneware vessels are generally used, but great difficulty has been found in their use when even 112° Fah. has been required, as these vessels would not stand the direct action of fire. Mr. Coffey has lately taken out a patent in connection with this subject that promises to be of great practical value. Descriptions of this patent will be found in the *Chemical News* and *Pharmaceutical Journal* of this month. The latter contains a well-executed drawing of the details.

Paraffin oil with a high boiling point is used as the medium for conveying heat to the vessel. By this arrangement earthen pans, or stills, may be worked with perfect safety at any temperature up to 600° Fah., or even higher. The furnace consists of an enclosed fire, over which is a coil of iron pipes. The paraffin oil is heated in this *coil* to any temperature, which temperature is indicated by a pyrometer, and is then conveyed

to the jacketed pans, where it can be turned off or on as required, as is usually done by steam. It circulates through the supply pipes and within the jackets of the pans in a heated state, but not under pressure, its boiling point being above the temperature to which it is subjected. As it cools under the influence of the work done, it falls by gravitation to the lower range of pipes and passes back to the furnace to be heated again. It will be seen that by this method of applying heat the difficulty that had been experienced in heating glass or stoneware vessels with high-pressure steam are entirely obviated. "We believe," says the *Pharmaceutical Journal*, "that in the first instance it was found difficult to prevent the oil from permeating the stoneware, and thus contaminating what was contained within the vessels, but we have been assured that the vessels are now so well glazed that no such effect occurs."

How far danger from fires is to be feared in connection with such a system of heating has yet to be proved; it is self-evident that the oils used must be carefully selected as regards a low boiling point, but if on trial this objection is found practically to be *nil*, Mr. Coffey has unravelled one of the operating chemists' practical difficulties.

TETRA-BROMIDE OF CARBON.

Messrs. Bolas and Groves make this substance by reacting on iodine and sulphide of carbon by bromine. Bromine by itself has no action on the bisulphide of carbon.

Two parts of bisulphide of carbon, 14 parts dry bromide, and 3 parts of iodine are heated together in sealed tubes to a temperature of 150° C for 48 hours; the tube is then emptied into a flask containing an excess of caustic soda in solution, and the mixture is distilled until no more tetra-bromide of carbon comes over with the water. It is then separated from water and crystallized out with hot alcohol. It is necessary to avoid boiling the alcohol, or loss occurs; terbromide of antimony may be used in place of the bromide of iodine.

Tetra-bromide of carbon is a white substance, crystallizing in lustrous plates, and melting at 91° C. It has an etherial odour, somewhat resembling tetra-chloride of carbon, and has a sweetish taste.

TANTALIUM AND NIOBIUM.

Mr. A. Leeds has writen a short notice of these substances, which originally appeared in the Journal of the Frankland Institute, and which also appears in the *Chemical News*. Tantalum and niobium were examined by H. Rose, and this examination occupied him during nearly twenty years of a most industrious life. Rammelsberg in revising these labours, recomputes the formula according to the modern theories of chemistry, and shows that Rose's deductions were wrong, not so much from the analysis, but from the formula he deduced from them thus:—Rose regarded as a chloride what was really an oxy-chloride.

Pure tantalium is unknown up to the present time. H. Rose employed to procure this substance three parts tantaliopotassic fluoride, and one part sodium. He obtained, however, only a heavy black powder, which contained a considerable quantity of bitantalate of sodium. Berezlius and Marignac attempted unsuccessfully to obtain tantalium.

Tantalic chloride was obtained by heating tantalic acid and carbon in an atmosphere of chlorine. It melts, according to Deville, at 241°6 C, and volatilizes entirely, forming a crystalline sublimate. According to the same chemist it fumes in the air, expels H Cl and becomes covered with tantalic acid. Its formula, as viewed from the experiments of Rose, and from the amount of chlorine it contained, was Ta Cl5.

Tantallic acid is white; when heated it is faintly yellow, and has the formula $Ta_2 O_5$. Its numerous salts are arranged by Rammelsberg in five series, corresponding to different stages of the saturation of the acid.

TEST FOR THE PURITY OF OLIVE OIL.

The following appears in the *Chicago Pharmacist* for June. It is said to determine in the most positive manner the presence of any of the seed oils (cotton seed oil in particular) in any given sample of olive oil. The test is a mixture of three parts of pure nitric acid, and one part of water; three grammes of the oil to be tested are mixed with one gramme of the test liquid, and the mixture is heated on a water bath. If the oil be pure the liquid becomes clearer and takes a yellow colour like that of purified olive oil, but if adulterated the transparency will be the same, but the colour red. With five per cent. adulteration the colour is characteristic, and with an adulteration of ten per cent. it is decisive.

DISSECTION OF THE DEAD IN HOSPITALS.

On Thursday afternoon, at the Southwark Police Court, the adjourned summons against Mr. John Charles Steele, M.R.C.S., superintendent of Guy's Hospital, who was charged in the early part of the week, under the Anatomy Act, 2d and 3d William IV., cap. 75, sec.7, with having unlawfully caused the body of Samuel Millbourne to undergo anatomical examination without permission of the person having legal possession of it, came on for hearing.

Mr. Oppenheim appeared for the prosecution; and Mr. Tyers, solicitor to Guy's Hospital, attended for Mr. Steele.

It appeared from the evidence of Carter Millbourne, residing in Bermondsey, that on the 1st of last month he took his father (the deceased) who was suffering from a stricture to Guy's Hospital, where he died on the evening of the 16th in the presence of his family. Complainant wished to remove the remains of his father soon after death, but he was told he could not do so until he had an order from the steward, who would be in attendance at nine o'clock on the following morning. Mr. Millbourne particularly reminded the nurse and the sister that no *post-mortem* examination should take place, but when the corpse was brought home on the following evening the head had been cut and mangled about as well as the other parts of the body. He immediately saw Mr. Steele, who said he was not aware that a *post-mortem* examination had taken place, and that he had given no orders for it, but he said it was usual under the circumstances of death that a *post-mortem* examination should have taken place.

Mr. Oppenheim now said that since the last examination the whole of the facts connected with the case had been carefully considered, and he had come to the conclusion that there was nothing to implicate Mr. Steele in the commission of the offence. When before his worship on the last occasion he considered it a very important case, and thought it ought to be thoroughly investigated. He (Mr. Oppenheim) was prepared to maintain that a *post-mortem* examination took place without consent, and that made it a misdemeanor at common law. He had recently ascertained that the examination was conducted by Dr. Moran and his assistants without the authority of Mr. Steele, and that the hospital authorities were determined to defend the case in the highest tribunals of the realm. It was therefore necessary that his client should consult his relatives and friends before he proceeded any further. What he proposed to do was to withdraw the summons against Mr. Steele, and consider what steps should be taken against other officers of the institution.

Mr. Tyers here observed that they had a complete defence to the case, whether against Mr. Steele, or any other of their officers. They were very anxious indeed that a case of such importance should be settled.

Mr. Benson had no hesitation in stating that there was no evidence against Mr. Steele, as he was not only unconscious of a *post-mortem* examination taking place, but was very much annoyed and offended at its being done, as it should not have been done without his directions. He was convinced from the *ex parte* evidence adduced the other day that a *post-mortem* examination had taken place, and that it was illegal. It was shown that rather indelicate haste was used, as the brains were deposited in the stomach. If done at all, he had come to the conclusion that such must have been the work of some younger gentleman of the profession.

Mr. Tyers informed his worship that the brains were removed to ascertain the seat of the disease, and it was impossible to replace them in the cranium. The medical authorities were compelled to make a perfect examination of the body before a certificate could be granted to the registrar as to the cause of death. However, they were in a position to prove that they had a right to make such an examination for scientific purposes.

Mr. Benson assuming that the evidence as given before him was true, "that the *post-mortem* examination was conducted for scientific purposes after protest from the son," he was of opinion that it was illegal. He acquitted the hospital authorities of the indecency spoken of in the presence of the son, "of the brains being placed in the stomach." That was probably the act of some young assistant, with an extravagant disregard for what was called sentiment. As far as the present case was concerned he believed that the nurse did not convey the proper message from Mr. Millbourne to the medical gentleman, and as there was not any evidence to implicate Mr. Steele, the summons must be dismissed.

WEDNESDAY, JULY 27, 1870.

ARMY MEDICAL DEPARTMENT REPORT FOR THE YEAR 1868.

This interesting report has been only a few weeks before the public, and well merits attention from all persons who occupy themselves with questions of public health. In France, as every one acquainted with Paris knows, there are statistical accounts of the mortality in civil hospitals, and hosts of entries have to be made by the medical men connected with these establishments. In this county, however, the Army Medical Report is the only one which can be compared with the elaborate reports of our lively neighbours. Should we ever endeavour to imitate the French nation, in attention to civil medical statistics, we cannot have a better model to work from than the elaborate report now lying on our table. The average annual strength of troops serving in the United Kingdom during the 53 weeks ending 1st January, 1869, appears to have been 78,261 non-commissioned officers and men. These troops seem to have had but a small mortality, only 9·34 per thousand having died during the year 1868. The deaths have been 3·16 per thousand from consumption, 1 per thousand from circulatory disease, and 1·32 per 1,000 from disease of the respiratory organs. The contagious enthetic diseases caused according to the report only one death in 10,000 men in 1868, although no less than 22,082 admissions into hospital occurred from these diseases. The troops in camps seem to have been much more healthy than these stationed in seaport towns, the mortality in camps having been merely 8·90, and in seaport towns 11·42, and as high as 15·27 in large manufacturing towns. In passing, we may remark that these facts point to the necessity, in any scheme for really raising the condition of our permanent fighting population, of following out some such proposal as that of Mr. Gleig, and establishing large military colonies (where the men may be allowed to marry) in some of our large open spaces, such as the New Forest. In this way the health of the troops would be excellent, they might be employed in some kind of productive labour, and the wives and daughters of the soldiers might find ample employment in the manufacture of the clothing and other articles required by the army. In this way, too, we should have the mortality of the troops reduced to a minimum, and they would always be in an efficient state, instead of being, as at present, so crippled by the immense amount of contagious diseases they suffer under and spread abroad in all directions in large manufacturing towns. At present, the soldier at home is perhaps more a curse than a blessing to his native land, as he sets a bad example to the rest of the adult population of "loafing" and other celibate vices, and, at the same time, is a constant seducer of, and infecter of, a large number of women wherever he chances to be stationed.

Under the heading of *miasmatic disease*, we find it stated that eruptive fevers have been more fatal in 1868 than in 1867. Measles and scarlatina were the most fatal. Only two cases of variola terminated fatally. Continued fevers were common at Dublin ; cerebro-spinal meningitis having been of frequent occurrence. Two sporadic cases of cholera are spoken of ; one at Aldershot proved fatal. With regard to *enthetic diseases* about which so much is said at present, it appears in page 7 of this blue book, that they were only 10 per 1,000 of strength below the proportion of 1867. Thus, in Colchester, in 1858, 537 per 1,000 was the ratio of such cases to mean strength of troops ; at Canterbury 407 ; at Dover 376 ; at Portsmouth and Gosport 348 ; at Dublin 333 ; at Manchester 312 ; at Shorncliffe 291 ; at Devonport and Plymouth 280 ; and at Chatham and Sheerness 275. At the Curragh 241 ; at Aldershot, 237 ; at Cork 209 ; at Woolwich 191 ; and at Edinburgh (not under any Contagious Diseases Acts) only 157 in 1,000. There was a marked reduction in the amount of this disease in Manchester, Edinburgh, and Woolwich (only the latter being under the Contagious Diseases Acts) ; the reduction at Devonport, Portsmouth, and Aldershot, all under the Acts, was but slight ; and there was scarcely any alteration in the amount at Chatham and Sheerness, Dublin or Windsor. The Household Cavalry at Windsor had a proportion of 1·33 in 1,000, diseased, and the Foot Guards 343 in 1,008. The increase of disease was marked at Belfast, Shorncliffe, and Winchester. At five of the stations the new fangled Contagious Diseases Acts were in operation during the whole of 1868, and at four of them there was a reduction in the amount of disease ; namely, at Woolwich, Devonport and Plymouth, Portsmouth and Gosport, and Aldershot. At Chatham and Sheerness there was scarcely any difference. We should be very glad to find out why Edinburgh had so little disease among the troops of the contagious or enthetic order. If the causes of this effect could be generalised, it might be of service to the unfortunate men who compose our present rather miserable, because necessarily celibate, army. Those who love the service of their country must deeply regret to see that there is a great chance of our British army becoming most unpopular among the women of the country, because of the infringement of the liberties of the poorer class of women which must ensue in all garrison towns if the Contagious Diseases Acts are to be carried in order to

save our stupid Executive from the trouble of thinking how our poor soldiers may lead a domestic life like the rest of the citizens. The United States, we all know, carried on the greatest and most bloody war the world has ever known by means of citizen soldiers, and we ask, as members of this noble country, why cannot we imitate that free and democratic State? Is it because, as a member of the present Government said, our aristocratic classes desire to maintain a system of out-door relief for their poorer relations at the public expense?

With regard to the details of localities where troops are stationed, it seems that the drainage at Aldershot is good. A lock hospital was in operation during 1868, and at Colchester a similar hospital was opened in January 1869. There occurred 25 cases of small-pox at Woolwich in 1868. None of these cases proved fatal. All recruits and children were vaccinated, and all others not bearing satisfactory evidence of protection. The statistics of venereal diseases at Woolwich show a decrease of about 68 admissions in favour of 1868 compared with '67. In the report concerning the south-western districts by Deputy Inspector-General C. A. Gordon, C.B., he says—"A main feature in the ventilation of barrack-rooms is that of providing a certain area of inlet and outlet communication with the open air, especially applied for ventilation, and irrespective of that by windows and doors." In the winter soldiers will not have the windows open in cold weather. It has been considered that if these special apertures are open and working, they will afford a removal of air twice every hour; that is, if 600 cubic feet of space are given per man in a barrack-room, that 1,200 cubic feet of air will be provided per hour. It has been deemed that with only 600 cubic feet per man with this system of ventilation, the air in winter can be kept sufficiently pure in a barrack-room. It has been advocated that more than twice the amount of air should be supplied—nearly 3,000 cubic feet. It is obvious, says Dr. Gordon, that to provide this amount in a cubic space of 600 feet would be a very difficult problem, as the removal of the air five times an hour would cause such a draught. Numerous experiments have shown that if the initial amount of carbonic acid in the air is 4 in 10,000 parts, the amount in a barrack-room thus ventilated will greatly exceed this; 10 parts of CO_2 in 10,000 of air becomes appreciable to the senses. It is a fact that the greatly improved health of the British army of late years, especially as regards the prevalence of consumption, is largely dependent on the increased space and improved ventilation of barrack-rooms, which may be estimated as fully occupied about nine hours out of the twenty-four. Should the space of 600 cubic feet be increased, asks Dr. Gordon? In well-constructed barracks at home, where this space and ventilation are secured, the air in them does not seem productive of epidemics, or diseases recognised as resulting from over-crowding. Typhus and ophthalmia are now rare among the troops, and phthisis and hæmoptysis, the deaths from which from 1837-46 were 8·7 per 1,000, were in 1867 only 3·3 per 1,000. The provision of a larger space than 600 cubic feet would, of course, be expensive. We have quoted these remarks as they are highly important, not only to army medical officers, but to all physicians and surgeons in this country. The most important element of hygiene is pure air, and the recent St. Pancras Infirmary dispute has made the question doubly interesting to London medical men. Dr. Beatson, in his report from Netley, remarks that the embarkation of the large bulk of invalids from India should be deferred till the departure of the late troop ships in March, and that the assembling of the divisional invaliding Board should be deferred in India until January. Hitherto it has been necessary, in order to get more away from India in January and February, so as to reach England, by the Cape, in May and June, to hold their Board in October, but Dr. Beatson recommends that they be allowed to remain in India during the cool months, after which there would be fewer invalids. Deputy Inspector-General Ferris reports from Devonport and Plymouth, that the health of the troops has been satisfactory in 1868. With regard to the working of the Contagious Diseases Acts, "there are many circumstances which render it difficult, arising in the civil population, and from the importation of disease by sailors from foreign parts, and prostitutes from unprotected districts. Until amended legislation has taken place, no very great results can reasonably be expected. The character of venereal disease has been favourably modified, rather than the number of admissions decreased. Less severe forms of disease are now met than formerly. It is to be remarked that cases have occurred where women have come from adjacent towns with the desire to be admitted into the Lock Hospital. I *regret* to state, however, that there have *not been so many women reclaimed* latterly as when the Act came into operation, *nor do they now contribute so much to their support.*" This latter fact any one with knowledge of the subject could have easily predicted. In Paris, the women are scarcely ever reclaimed since the horrible police system came into vogue, and this will inevitably be the case if we continue to imitate the French and make our standing celibate army an excuse for handing over our poorer women in garrison towns to a life of white slavery as in France.

From peaceable Scotland there is not much news about the army. Only 3,179 troops were stationed in that country in 1868. Not a single case of small-pox or cholera occurred in the course of the year. At Edinburgh the men have 502 cubic feet per man, at other barracks 600 or more. In Ireland during the year, considerable expenditure has arisen from extending the cubic space available for troops. In the districts at a distance from the capital, the proportion of cubic space has usually ranged at from 400 to 500 cubic feet. At the Curragh Camp and district seven school rooms have been converted into recreation rooms, and these offer every inducement to the well-disposed to resort to, instead of to the tap-room. There are books and papers of all kinds supplied, with chess and bagatelle. This is truly a humane provision *at last.*

With regard to re-vaccination, a subject which is pregnant with interest, at a time when our friends in Paris are suffering so terribly from the curse of small-pox, the results of vaccination are given in 2,264 soldiers and 15,183 recruits. In the case of the soldiers not recruits, about one-third gave a perfect vaccine pustule, on re-vaccination (330 in 1,000), 280 in 1,000 a modified pustule, and 389 in 1,000 failed. Of the recruits, 292 in 1,000 gave a perfect pustule, 344 a modified pustule, and 363 in 1,000 vacciuations failed. With regard to the number of men who, on being examined, were found to have marks of vacciuation, in London 915 in 1,000 had been vaccinated, and in Glasgow only 832. In Dublin 968 had been vac-

cinated, and in Belfast only 785 per 1,000. Ireland still continues to furnish the highest ratio of unprotected men.

The influence of age on the mortality of the troops is a very interesting subject. In the civil male population of healthy districts in England and Wales the mortality per 1,000 annually under 20 is 7·41; between 20 and 25, 8·42; between 25 and 30, 9·21; between 30 and 35, 10·23; between 35 and 40, 11·63; and after 40 it is 13·35. In the whole of the troops it is in similar periods 3·68, 6·65, 7·28, 12·77, 17·32, 12·49. Thus, before the age of 30 the life in the army seems to tend to increase the longevity of the citizen; but after this age, to diminish it. With regard to recruiting for the army, 23,543 recruits were primarily inspected during the year 1868, and the numbers rejected were 8·847, or 376 per 1,000. The ratio found unfit for service at primary inspections were, in London 373, in Liverpool 404, in York 103, in Glasgow 501, in Dublin 381, in Belfast 276. The most frequent cause of rejections were diseases of the eyes and eyelids, varicose veins, malformation of chest and spine, diseases of the heart, muscular debility and defects of lower extremities. When we look at the occupations of the recruits we find, that of 1,000, there were rejected 374 in the classes of labourers, husbandmen, and servants; and 414 of the class of mechanics, such as carpenters, smiths, and masons, while only 347 shopmen and clerks out of 1,000 were rejected. It must be remembered, however, that by far the largest proportion of recruits offering themselves came from the classes of labourers, artizans, and mechanics, so that it is difficult to draw any good comparison as to the fitness for active service of the different classes from this Report.

THE CLUB DOCTOR.

The club doctor's position is one of importance to our Profession, and our object in referring to him is in order that we may, if possible, recommend a means of improving his social *status*, not only as regards his position towards the members of society of which he is medical officer, but also with respect to the emoluments he receives for his professional services thereto.

There are few Societies, Lodges, or Clubs subject to the provisions and entitled to the privileges of the Acts relating to Friendly Societies but possess, or have specially retained for them, the services of a duly qualified medical gentleman for the purpose of examining candidates about to join the Lodge, and for attendance upon the sick or injured members. These societies are generally found very useful to the working man and his family in the time of sickness, there being a weekly allowance from the "box" and gratuitous medical attendance, as well as, in case of death, the relations being entitled to claim a specified sum of money in order to cover funeral and other incidental expenses attending it. But, we hold, the doctor's position, according to existing rules, is neither honourable nor lucrative. In the first place, Lodges are generally connected with public houses; their meetings are held there, and the doctor is not unfrequently summoned to attend a meeting for some paltry explanation at a low beer shop, where gentle stimulation from the pewter cup is necessary for transacting the business of the meeting, and it is rather *infra dig.* for an educated gentleman to be mixed up in their proceedings, if we may judge of the disorder which exists at the majority of these club meetings. Of course, there are exceptions where the rector or vicar takes the Village Club under his fostering wing, preaches concord to them, and insists upon their meeting and conducting the business of their society in his school house; but the majority of them do not transact their work in this way. The club is essential to the trade of the beerhouse host, and he supplies the luxuries—what the parson does not look upon in the light of necessaries, but which, nevertheless, are very acceptable to most of lodge members. The chief duty of the medical officer is to carefully examine every candidate for admission into the society, and certify as to his constitution, state of health, and supposed age. To attend upon all sick members in time of illness; to supply them with proper and sufficient medicine; and to give certificates whenever required, either for their weekly allowance from the funds of the society, or to the effect that health is sufficiently restored to enable them to return to their employment; and all this work we find for an average payment of three shillings a member per annum. Some societies pay more, others less, the majority three shillings, and the average amounts to three shillings a member for twelve months, medical attendance and medicine to be supplied in addition—the ordinary fee charged by the general practitioner for a single visit and a bottle of medicine in the provincial districts of England! Now, we are informed by some club doctors that they attend certain clubs at disadvantage and actual loss. Two or three patients suffering from chronic disease swallowed up all the emolument, for they take good care in most instances to be exacting, and remind the doctor that they are not paupers. No, not paupers, but they are worse; they expect great things for a paltry three shillings, and forget that for attendance upon paupers the doctor is paid more, and is not bothered with entrance examinations and the certificate writings expected of him. If a Colliery Company contract with a medical man they never think of offering less than ten shillings for attendance on each man the current twelvemonth, but here throughout the length and the breadth of England we have clubs only paying their doctor three shillings a case! If a club wants to flourish and grow rich as to its funds, the public house is not the place to meet, for many reasons too apparent to be dwelt upon here: and if a club wants to have proper medical attendance, and the sick members properly treated and supplied with medicines—for the interest of the club is, and the object of the doctor ought to be, to restore the sick member to his original usefulness as speedily as possible—they must pay for it. A medical man may take a club, or a number of them, at a low figure, not with the intention of making money out of them, but to keep his patients together and keep out opposition in his practice. He will find the fallacy of this after a time, for his services are valued at the price he puts upon them, and the consequence is, unless he quickly cures his patients, he discovers himself superseded by the nearest gentlemen who knows how to value himself and respect his Profession. Again, young men commencing practice underbid their seniors in order to obtain clubs, with the view of an introduction to practice, and we ask are they respected in the end any more for doing work cheaply? The members of the Profession keep crying out against the small fees paid to them out of clubs. We tell them now the fault lies at their own door: as societies have laws to guide and direct them, so ought club doctors to put their heads together and have an universal system for their guidance—a scale of charges from which no one can deviate; for although a tradesman to oblige his customers may for their convenience keep a certain article from which, or out of whose sale, he obtains no profit, we remind our brethren that a profession is another thing very different indeed, and that it is a very poor excuse for a surgeon to say, "I retain my club at so small a fee merely through charity, or in order to oblige my patients." If through charity, let him do the work for nothing; and, as to obliging patients in such a matter, it's a poor excuse for a mean act. After careful consideration of the subject, we find no man can safely undertake the medical charge of a lodge whose members are less than fifty under at least seven shillings a member; and above fifty and under a

hundred six shillings. In no instance should any medical man take less than five shillings. Should he do so, he must either neglect the case or lose by the transaction. In all clubs we consider the best arrangement would be for no medical man to be regularly appointed, but for each member to choose or select his own doctor. This principle, combined with medical men who hold club appointments agreeing to a fixed scale of fees, would be of great benefit to those of our brethren in the future who may be desirous of obtaining clubs, and this, we predict, would be of equal advantage to the "*Box*," because, as we have said, it is the interest of the Lodge to have no sick, and when a member is ill to have him restored as speedily as possible; and a doctor cannot be expected to devote his time, or bestow upon the case much thought or attention, unless he is paid fairly for the work he has to perform.

Notes on Current Topics.

Honour where Honour is due.

In our uphill struggle and hard battle as physicians it is refreshing at times to find the daily journalist in his act of public duty paying such a tribute as the following to a deceased member of our noble Profession, more particularly at a season when heavy reflections are being cast on certain members of us as yielding to the desires of cruel artifice and infamous stratagem :—

"A Good Man.—It is our melancholy duty to record the death of Dr. William Martin, of Ratcliffe-on-Trent. He died on Monday, the 11th inst., at Buxton, whither he had gone for the benefit of the baths. * * * To say that Dr. Martin was generally esteemed and will be deeply lamented would be only repeating a form of words, which by their frequent use and sometimes inappropriate application have become stale and hackneyed! Yet here they may be used in all their plainness and literalness. He was loved and respected by the rich and poor, but it is the latter who will feel his loss the most keenly; to them he was a friend as well as a doctor—ever ready to attend upon them at all times, both by night and by day, and under all sorts of circumstances; and his generous forbearance and tenderness towards them when times were hard—very often assisting them with money when he himself was as hard, or harder, pressed than they were—will never be forgotten by the many who were the objects of his liberality. He has fought life's battle bravely and honourably! He has done his duty as only earnest and conscientious men do it, and he has fallen whilst in the discharge of that duty; stricken down by the result of a cold caught when out on a long visit amongst his patients! No man in the parish will be so much missed as will the doctor, and they will all feel that he must and will receive from the Master the 'Well done' of the good and faithful servant, for according to his ability and and strength he hath walked uprightly and worked righteousness, and spoken the truth from his heart."

Of how many of our provincial brethren might not the same be written! but to the public their work is veiled, they labour by stealth, and are not appreciated as they deserve.

Miss Nightingale on Small-pox.

There was a meeting of anti-vaccinators at the Town-hall, Manchester, on June 28th, which was presided over by a late distinguished Professor of Latin in University College—Mr. F. W. Newman. Among other things read aloud by the honorary secretary, Mr. Pitman, who seems to mix up good and bad things in an unfortunate way—associating co-operation with anti-vaccination, and such like untenable contests with medical science—there was a letter from a doctor of the name of Garth Wilkinson, whose name we have seen connected with a pamphlet of very bad taste against the Contagious Diseases Acts. This gentlemen in his epistle quotes the honoured name of Florence Nightingale as having said in her "Notes on Nursing"—"I have seen with my own eyes, and smelt with my nose, small-pox growing up in first specimens, either in close rooms or in over-crowded wards, when it could not by any possibility have been caught, but must have begun." We would ask Miss Nightingale, if this be the case, why small-pox did not exist among the Romans, and why it never breaks out in Ireland now-a-days, since vaccination was so commonly carried out there? Crowding is still very common in Dublin and elsewhere. It would scarcely be necessary for us to ask such questions if Mr. Newman, Mr. Pitman, and other philanthropic persons, would but read some medical works such as those of Mapother, Guy, or Cameron, or Parkes on hygiene. Why will they confine their reading to non-scientific literature, or little pamphlets written by some crotchety individual?

The Medical Bill.

The Royal College of Surgeons of Ireland has been represented in London at intervals extending over several weeks by a deputation consisting of Mr. Macnamara, the ex-president, and Mr. Hargrave, representative of the College in the Medical Council. These gentlemen have been charged with the surveillance of the Medical Bill, and as long as the 18th clause of the Bill, as originally introduced, existed, they, by direction of the Council, exerted their influence in its favour. Inasmuch as the removal of this clause, and the introduction of the third subsection of the tenth clause, not only utterly destroys the uniform operation of the measure, and abrogates the principle of universal State supervision, but concedes to Universities most unjust and dangerous facilities to continue the diploma-selling system, the Council have now decided to employ all their influence to reject the Bill, or postpone it until next year. With that view they reappointed the deputation on Saturday last, and, having already petitioned the House and addressed the Irish members on the subject, they are moving most vigorously against the perpetuation of petty monopolies and education downwards which the Bill aims at.

The Reports of Medical Officers.

The following general order has been published in India :—

"It has lately been brought to the notice of the Commander-in-Chief in India, that a medical officer in charge of a regiment has reported matters of discipline connected with the medical subordinates attached to the corps to the superior medical authority on the spot, who is powerless to take action in such cases, and has neglected to make any report of the occurrences to his regimental commanding officer. The Commander-in-Chief desires it to be pointed out that this course must necessarily occasion delay in the final settlement of such cases. It is the duty of a medical officer to bring all matters of this nature, in the first instance, to the notice of his commanding officer, under whose immediate orders the medical subordinates are serving, and who is held responsible for the discipline of all under his command."

Indian Medical Service.

In the House of Commons on Monday week last Col. Sykes asked whether an examination of candidates for the medical service in India would be made in the spring of 1871, as it was understood an examination would not be made in the present autumn—Mr. Grant Duff: "I regret to say that I am unable to answer the first question. It is quite possible that there may not be an examination next spring, as it is understood that the medical service is rather overmanned at present. We have, however, written to India asking for precise information as to immediate requirements, and I can state nothing definite till we have an answer."

The Medical Services.

The *Poona Observer* has it on the most reliable authority that it has been decided to amalgamate the Indian and British medical services, and that the Government of India has been entrusted with the arrangements of details regarding pensions, funds, subscriptions to be paid for those who elect for general service, &c. The deputy-inspector-general of hospitals only will be offered an inducement to retire. No others below that rank will be considered, but those who have reached fifty years of age will have to retire compulsorily. This latter is as it should be, there being few or none of that age that are equal to the duties they have to perform, either in professional efficiency or physical strength and vigour of mind. Considerable difficulty manifests itself at the Horse Guards as to the disposal of all those native or coloured gentlemen who have, to their great credit, qualified themselves for the Army as assistant-surgeons. The Duke will not have them with European regiments at any price. This hardship may be overcome by these gentlemen receiving a *placebo* in the form of a first-class civil surgeoncy each, and so retain them in India. Other difficulties, in the way of medical and military funds, present themselves, which the Government of India is called upon to solve. The head of the department of each presidency will be called upon for opinions on certain matters; and it will give each an opportunity of showing his interest in his department, and the support he intends to give the junior members of the medical service.

Mr. Cæsar Hawkins.

The thanks of the Council of the Royal College of Surgeons of England have been voted to Mr. Hawkins for "his services to the College as its late representative" in the Medical Council. This is what we should have expected. Mr. Hawkins, one of the Council of the College, was appointed by the other Councillors, and so should be thanked by them, if by anybody. The fellows had no voice in the matter, still less the members, though these are supposed to form the College. Surely, it would have been a greater honour to have represented and be thanked by the College, than the small section of it that attain the post of Councillors. Well, the outside fellows and members need only say they have no part in thanking Mr. Hawkins for benefits they have never received.

Mr. Quain.

At the same meeting these Councillors nominated Mr. Quain, as we have already stated, to succeed Mr. Hawkins. He is in a worse position, inasmuch as the question has come prominently forward lately; and, in taking the office in this way, Mr. Quain must be aware that he will act against the feelings of the majority of the Corporation he is to represent.

If the Council had called a meeting of fellows and members, and recommended Mr. Quain, he would have been certainly elected unanimously. No one would have brought forward a more likely representative, simply because they could not do so. Mr. Quain's popularity is as well known as his ability and honesty, and we should have been glad to see him elected by such a constituency. But, we protest again, in the name of the 17,000 members and fellows, that we are unjustly and illegally prevented from having part or lot in this matter.

The Junior Councillors.

Everyone knows the prestige that attaches to seniority in the Councils of most bodies, and in none less than the London College of Surgeons. The members and fellows throughout the country will, however, be pleased to hear that their Junior Councillors have not been wanting, but have already redeemed their promises. Our readers will remember that when Mr. Erichsen was elected we congratulated them that at length the voice of a true liberal would be added, and we are able to say that in the recent election he took the popular side. At that meeting Mr. Henry Lee and Professor Erasmus Wilson took their seats for the first time. Last year and this we spoke up for both these gentlemen, and in some quarters were thought rash in doing so. The event has proved we were right. Mr. Lee spoke as a true man should on the rights of fellows and members—in fact, he carried out thoroughly the policy he promised in the letter he published. We told our readers last year they might trust him for all he said, and all his words could be construed to imply; and we are, therefore, glad to be able so soon to justify our predictions.

Mr. Wilson, too, if he did not go so far as to refuse to vote, did say he felt fellows and members should have a voice in the election of a representative of the College in the Medical Council. We have, therefore, every reason to be satisfied with the conduct of our new Councillors, and to hope they will maintain the independent and liberal spirit they have evinced. For the future, let it be understood that this one test alone shall be applied to every candidate for election, and even for re-election, into the College Council. Let the fellows but be true to themselves, and no one who has not given a pledge on this point will ever again obtain a seat at the Council table.

Mr. Gay's Proposal.

At the same meeting of the London College Council, Mr. Gay gave notice of the following motion he would bring forward:—

"1. That, in the opinion of this Council, the Royal College of Surgeons of England is entitled to a greater number of representatives in the General Council of Medical Education and Registration of the United Kingdom than that which is assigned to it by the Medical Act of 1858. 2. That, in any increase of number, provision should be made that one at least of the representatives of the College should be elected by the Fellows and

Members. 3. And that a copy of the foregoing resolutions be forwarded to the Lord President of the Privy Council."

The last part of this resolution we advise Mr. Gay to drop, as the Lord President might possibly make some unpleasant reply as to the selfishness with which he proposes to keep so much in the hands of the few. As to the other, there is something to be said when the College of Surgeons shall become in fact what we desire it to be. The Council of the College is but a select body of a couple of dozen eminent men. The same may be said of the ruling body of the University of Durham. Each sends a representative to the General Medical Council. But let the members and fellows of the College and the graduates of the University be the constituency, and then the one would be 16,000 or 17,000; the other—how many dozen? This is a strong point in favour of what has been rather improperly called "direct" representation, while it does not tell against what has been more improperly stigmatised as "indirecet" representatiou. We, who have advocated both methods, are not disconcerted, nor would the carrying of Mr. Gay's motion at all astonish us; for we know there is liberal thought enough in the College Council, and there is also the remnant of an unwise distrust of the fellows and members. But such a compromise will not do. The executives of our corporations—not of this College alone, but of all—must show more trust in those who elect them; must be willing to recognise that they are not, and cannot be, the corporations; that the glory of being one consists in the numbers of worthy members of the Profession enrolled in its ranks, and the interest these feel in its welfare. We ask Mr. Gay to study these points before he proceeds.

A COMMITTEE of the British Medical Association have been occupied in objecting to the Bill, unless representation in the General Medical Council be obtained. Dr. Waters, the indefatigble chairman of the committee, has spent several days in London working to this end. A petition, signed by Dr. Waters, has been presented on behalf of the Society. It is carefully and exactly drawn up, and we regret that space is too limited to give it entire, but some parts of it are exactly like others which we formerly published. We gave a paragraph or two of this last petition:—

"That, owing to the medical practitioners having no direct representatives in the Council, the profession evinces but little interest in its proceedings—a disadvantage which has been admitted in the debates of the Council.

"That corporate interests only were considered at the special meeting of the Council held in April and May last to consider the provisions of the Medical Acts Amendment Bill; while the representations and wishes of the profession were disregarded.

"That the Council, as at present constituted, no longer possesses the confidence of the profession.

"That the introduction of representatives elected by the profession would give the profession more confidence in the Council than at present, and would also increase the knowledge of the Council with respect to the needs of the public and of the profession in Medical Education, Sanitary Measures, Medical Jurisprudence, and Poor-law Medical Relief.

"That a Bill has been brought into your honourable House intituled the 'Medical Act, 1858, Amendment Bill,' and that no provision is therein made for the direct representation of the profession in the General Medical Council, although the payment of the representatives of the several universities and corporations, and of the representatives of the Crown, together with the general expenses of the Medical Council, amounting to upwards of £4,000 annually, are defrayed, not by the bodies so represented, but solely by fees exacted from the Medical Practitioners of the United Kingdom on Registration.

"That various medical societies in the large towns of England, as well as branches of the British Medical Association, have passed similar resolutions.

"That the Irish Medical Association, the President and Fellows of the King and Queen's College of Physicians in Ireland, the Royal College of Surgeons in Ireland, have passed resolutions in favour of Direct Representation.

"That the Royal College of Physicians, Edinburgh; the Royal College of Surgeons, Edinburgh; the Faculty of Physicians and Surgeons of Glasgow, and various medical societies in Scotland, have petitioned for Direct Representation.

"That the election of direct representatives by the registered members of the profession can now be readily effected for each of the three divisions of the kingdom by means of voting papers."

Baby-Farming.

IN the course of our remarks upon baby-farming, we drew attention to the fact of London not being the only nest for the cormorant who eked out existence by trading in the destruction of children. We spoke of the old woman in country places, who "cares the love child and neglects it," and we recommended the police to be communicated with by those who knew the existence of any farm in their neighbourhood. We admire, accordingly, the manly step taken by the Rev. Mr. R. Thorpe, the incumbent of Christ Church, Camberwell, who applied on Thursday last at the Lambeth Police Court to Mr. Elliott, in order to solicit his advice and assistance respecting the existence of two baby-farming establishments in his district. Being unable to prove actual ill-usage, although the reverend gentleman has alleviated the condition of the children (if carefully tended or nursed, why require alleviation?), the presiding magistrate could not advise him further than for him to communicate with the police. We think the most advisable course to be adopted will be for these farms to be placed under the jurisdiction of the Poor-law medical officer of the district wherein they exist, and that this gentleman visit these children as he does the imbecile and parish lunatic, for which he is paid 2s. 6d. per quarter; that, if he suspect unfair treatment, or neglect, he send them into the workhouse; and that he send in a return of all such children in his district to the Board of Guardians each quarter day, being remunerated, of course, per case, as for pauper lunatics. The licensing system raised by a contemporary would never work in country districts; and the parish doctor we conceive to be the proper official to visit these farms, and, if he find anything suspicious, order the children to the house, and hand over the superintendent of the farm to the police.

The Faculty of Imitation.

WE believe those who have the faculty of *imitation* highly developed are fond of taking advantage of the general doings of others. Last week we were treated to a leading article in the *Lancet*, which indisputably proves the writer has been reading our recent remarks in the MEDICAL PRESS upon "Spermatorrhœa," and other papers on the same subject lately published by Mr. Teevan and Dr. Waring-Curran. When the editor of the *Lancet* merely recapitulates the practical views of other men, we think that he should acknowledge them; but since he winds up with the remark—"We know with certainty very little about the actual prevalence or those direct effects of

self-abuse," we pity him, whilst we object to the pompous tone of second-hand effusions built upon the labours of others, and with the *Lancet's wonted* generosity and self-sufficiency unrecognised.

Cucumbers.

The cucumber is the favourite luxury of the working-class; consumed with great gusto, regardless of consequences, and chiefly eaten at tea or supper by them. The cucumber found in the market is generally obtained from plants *forced* in a warm damp atmosphere. When the heat of the day is greatest the plants are watered, and then the windows of the frame lid closed, and the action of solar light prevented by covering the panes with a blind. A kind of steam is thus generated in the interior of the bed, and the fruit forced to grow with great rapidity. This is generally the variety known as the black spined long prickly, a contrast to the sandy cucumber grown in the open fields of Bedfordshire. Our object here is to remind lovers of this vegetable that, in addition to the saccharine and nutritious elements entering into the composition of the cucumber, we have also acrid and purgative principles, found not unfrequently in a state of concentration, hence accounting for the great suffering and alarming train of symptoms induced after a surfeit of this fruit. We have known last season, many cases, at one time dangerous, which we had no hesitation in pronouncing to be dependent upon cucumber poisoning, and entirely owing to utter carelessness and incaution in dressing and eating this vegetable. We consider before using the cucumber it should in every instance be sliced and purged of the preponderance of its acrid and purgative elements by treating with a little salt and then saturated with vinegar for some hours previously—never eaten without, in fact—otherwise it is very apt to produce an active and severe form of purgation, accompanied by intense pain and constituting the so-called *choleraic diarrhœa*.

Vital Statistics of Salford.

At a meeting of the General Health Committee, March 3rd, 1870, the Officer of Health for Salford submitted the vital statistics for 1869. The death rate has been 26·64 per 1,000, a high one. The birth rate was 39·35. This is generally the case—whenever birth rates are high the people are poor, uncivilized, and die early. Salford, it seems, had in 1869 the fourth highest birth rate and the sixth highest death rate of fourteen towns mentioned by the Registrar-General. In 1868 it was even worse. Salford had then the second highest death rate and the third highest birth rate. The citizens of Salford have, therefore, the great lesson to learn that, if they propagate so fast, they will live miserably, and die young.

Scotch Medical Celebrities.

It is somewhat remarkable that the four very distinguished members of the Profession who have recently departed from among us—Drs. Simpson, Clark, Copland, and Mr. Syme—were all of them citizens of the modern Greece, as it has been called by some recent author—Scotland. No one can doubt that Scotland is far in advance of the rest of the Kingdom in its philosophy; and without sound philosophy no character is ever complete. The two heads of the modern school of philosophy, Mill and Alexander Bain, have both received their prophet's mantle from Scotch philosophers. If positive thought is soon to be dominant among English-speaking nations, it will be mainly owing to the thinkers of Scotland; and medicine, being a science essentially positive in its aims, has gained incalculably by the Edinburgh School which retains the traditions of Reid and Hume.

Iodide of Potassium.

This important drug appears usually to be sold in a state of great purity, although it is very dear, being sold at two shillings an ounce by most druggists, or 3d. per drachm. It would be of importance if it could be sold at half the price, as it is admitted in large doses in modern practice in syphilis.

Mr. Cock.

Mr. Cock, stimulated by the paragraphist who sends college trifles to the *Times*, has informed that journal that he is not the first president to throw open the College doors to the fellows and members; but that the late meetings have been held under regulations established by the Council. As Mr. Cock's period of office is now over, and Sir Wm. Fergusson has succeeded him, it is, perhaps, not too much to say, that there is a general impression abroad that the president possesses very great influence, and that in Mr. Cock's case that influence was thrown on the side of liberal conduct towards members and fellows. We may add, that seldom has the College had a president so zealous in the discharge of all his duties and who devoted so much time to College matters. For this reason we deeply regret that he was not able to call the meeting, so gracefully asked, to discuss the question that now is foremost in medical politics, during his term of office. We can now only appeal to Sir W. Fergusson to call such a meeting, and thus honour his predecessor by doing that which he would himself no doubt have done, after the respectful request he received at the last meeting.

Free Medical Education.

M. N. Pascal, in a letter to the *Mouvement Medicale*, says:—"A professor well known by the treasurers who paid him, and better known in the learned world on account of the twelve places he occupied undes Louis Philippe, than by the services he has rendered to science, said, with the princely contempt which belonged to him, 'You men of free education are but dried fruits:' to which one of the professors of the free school replied before his pupils, 'Dry fruits are always more valuable than rotten fruit.' The 'dried fruits' are content to teach what they know, and they only tell us to-day what they know. This Velpeau, when he was a free professor, dedicated his principal work to medical students, because they made him the most sought after of all professors, and to his father-in-law, M. Quesneville, 'author of his domestic happiness,' showing by this that between pupils and teachers, and between children and parents, the relation is similar. It is true that when the garment of Nessus touched his shoulders he suppressed this dedication. Was, perhaps, his teaching more valuable after than before? And Pajot, who for twenty years has taught midwifery to ten thousand pupils, and has not denied liberty, and who would to-morrow have more

pupils than all of the faculty if the Grand Amphitheatre were closed. Do you call these men 'dried fruits?' Let us hasten to say that the demonstration of the inferiority of the official instruction has no longer any need of being made, except to first year's students. Advanced students, and foreign medical men who visit our cliniques, quickly make up their minds about some of our faculty, and do not hide their sentiments." Decidedly the Parisians are a revolutionary people.

Signs of Death.

It will be remembered that a bequest has been recently made to the Academy of Medicine of Paris for the purpose of enabling the Academy to award annually a valuable prize for the best means of unfailingly demonstrating the existence of death and thus guarding against premature sepulture. M. Bonchut has suggested that the contraction and dilatation of the pupil by calabar bean and atropine is a reliable test and one capable of being employed without suffering or danger to the patient.

Tubercular Meningitis.

Dr. Vogel, in his work on Diseases of Children, denies that it is possible to prove the absence of inherited taint in this fatal disease, and, from several years of large practice in a poor district, he concludes that tuberculosis is far less common than it would be if external conditions had much influence in its production. He regards the arachnoid as the seat of tubercles in this disease. He observes that in this disease it is always to be remarked that an older, larger, yellow tubercle exists somewhere else in the body. He condemns the use of mercury in this disease.

Croup.

Dr. Vogel, of Dorpat, Russia, says that both emetics and tracheotomy are useless in croup, which in well declared cases may be set down as a fatal disease. He believes that the reason why Trousseau succeeded so often in his tracheotomy cases was because diphtheria is common in that country and that croup is often confounded with catarrhal laryngitis.

Lady Doctors.

M. Nelaton, M. Milne Edwards, and M. Duruy, are anxious to found a school of medicine especially for women. The Parisians don't marry much now-a-days, so it does seem fair that the girls should be allowed to compete with them for the good things of this life, as well as to go into nunneries, which have been called clubs for spinsters.

Female Doctors in France.

The female medical agitation is assuming important dimensions in France. Already the proposal to erect a free medical school for women has been submitted to the Empress by Messrs. Duruy, Nelaton, Husson, and Milne Edwards. Probably France will soon rival America in the movement, and it is not only there that American ideas are taking root. In London a royal decree has authorised women to practise medicine after they have undergone the usual tests of efficiency, and a special course is about to be created for them in the Caroline Institute. In Vienna, also, the Professors of the University have decided that women shall be admitted to follow out the curriculum and attend hospital.

The Vienna University has decided to admit women to its curriculum, and two ladies are studying there.

Scarlatina, measles, and diarrhœa have been recently very fatal in Marylebone.

Mr. Gladstone is said to be in excellent health again.

Already £1,740 has been raised for the Syme Testimonial.

The will of Sir James Forbes Clark, M.D., F.R.S., has just been proved under the personalty of £25,000.

War fever rages in Paris at present. Its symptoms are delirium, belief in murder, and an insane desire to kill and be killed by some person.

The culprit John Jones, who murdered the family of seven in such an atrocious manner at Uxbridge in May, received sentence of death on Friday last.

Fever unfortunately continues to increase at Liverpool. In the Workhouse Fever Hospital last week there were 229 cases, as against 186 in the preceding week.

Dr. Thomas Reade, of Belfast, asserts that he was one of the first observers who published cases of syphilitic disorders of the brain and its membranes in 1851 and 1852.

The Committee for Hospital Organisation is progressing favourably, and holds frequent meetings. The programme, we hear, is Provident Dispensaries and Consultations at Hospitals. We wish them all success.

Mr. John Hilton, F.R.S., surgeon extraordinary to the Queen, after holding the office of surgeon to Guy's Hospital during more than twenty years, was unanimously elected consulting surgeon to that institution. Sir Astley Cooper, Bart., was the last surgeon elected to this same office at Guy's.

Dr. Broadbent reports that a large number of cases of typhus fever have occurred in London during the past week or two, immediately following in the wake of the relapsing fever epidemic, which had assumed somewhat alarming proportions.

The election of a head master of the Royal Medical College at Epsom, in the room of the Rev. Dr. Robinson Thornton, presented to the wardership of Trinity College, Glenalmond, will take place in the course of the present week. The stipend is £700 a year, with a furnished house.

Mr. J. G. Brough has been appointed Librarian of the London Institution. Mr. Brough for ten years edited the *Chemist and Druggist*. We are glad to hear our contemporary will still obtain some original contributions from his pen, although it loses his services as actual editor.

The meeting of the British Medical Association, at Newcastle-on-Tyne, on the 9th, 10th, 11th, and 12th of August, promises to be interesting. The annual Museum originally instituted by Mr. Jonathan Hutchinson will be repeated, and books are also to be exhibited.

The Committee at work on the out-patient department of our London hospitals seems anxious to do what is right. Another meeting has been held, and one more takes place to-morrow. The work is difficult and full of questions that may excite impatience. We therefore ask for the extra indulgence to which it is entitled, and which we know will be cheerfully given to any of its suggestions.

We have been examining carefully the list of gentlemen nominated for the Fellowship of the London College of Physicians. Some of them well deserve the honour; and, if others would not have occurred to us as those who ought to be promoted at present, we do not think it worth while to mention names, especially as the election does not take place until to-morrow.

Dr. Russell, of Birmingham Hospital, has related a case of large aneurism of the basilar artery, with local disease of the arteries, and superficial softening of the pons varolii, giving rise to two distinct and protracted attacks of hemiplegia, each followed by recovery, and then followed by paraplegia. All of these occurred in a male, aged twenty-six, who had contracted syphilitic contagion six years previously.

Mr. Haviland last week gave a descriptive lecture, on the Geographical Distribution of Disease, at the rooms of the Social Science Association. It was illustrated by a series of coloured maps showing, according to the Registrar-General's returns, in what localities certain diseases prevail. Mr. Haviland has devoted much time to this subject, and, whatever may be the theories propounded, the accumulation of facts cannot but furnish material for investigation.

Small-pox in Paris continues to be very fatal, although there is some decrease in the mortality—225 instead of 267 in the week. Altogether 3,674 people have been swept away in this epidemic. Mr. Newman and other vaccino-phobiacs think this is a trifle compared with their allegations (never proved), that here and there inconvenience or danger may result from vaccination. Mr. Newman may have taught Latin well, but Heaven save us from his logic, which consists in one single phrase—*post hoc, ergo propter hoc*—the natural motto of quacks and fanatics.

SCOTLAND.

Dr. John Wylie, Edinburgh, is to begin a course of lectures on Pathology in November in connection with the Royal Colleges of Physicians and Surgeons.

Relapsing fever has not altogether disappeared from Edinburgh, several cases having recently been admitted into the Royal Infirmary.

SPECIAL CORRESPONDENCE.

PROSTITUTION IN MADRID.

FROM OUR OWN CORRESPONDENT.

Madrid, July 22th, 1870.

As for some time there has been so much discussion of the question of the Government regulation of prostitution going on in your pages, I may perhaps be permitted to say a few words about what is thought of such measures in Spain, notwithstanding that rumours of war are at present of more stormy interest than any sanitary question, however important.

Dr. Machucho, an esteemed physician, has recently written advising the application of the French police system to Madrid, and it may be as well to let some of your readers hear what reasons he assigns for his desire to make such an innovation. He truly remarks, in the words of the Abbé Constant, that prostitution is not a crime, but rather a condition of suffering, to the majority of women who are obliged to have recourse to it from poverty or other causes. He is, as most medical men are, a foe to the prohibitory theory of Catholic countries, but is in favour rather of liberal measures. He observes that he does not belong to the class of austere moralists who in this matter carry their opposition so far as not to accept authorised prostitution, under the pretext that it will thus become an industry protected by the State. Such an argument, he observes, would come well from the mouth of Philip IV., who made the tolerated houses to be shut up and the prostitutes put in prison. In all nations, says Dr. Machucho, when any attention is paid to public health, in all free, just, and illustrious States, Governments have thought it right to regulate and watch over prostitution, in place of absolutely prohibiting it—a measure which would be equivalent to consent that it should be privately carried on.

Belgium has made, especially in Brussels, a kind of law concerning prostitution, which is superior to the Parisian law, which latter has established a special service known under the appellation of "office of morals." This Parisian system, though incomplete, has opposed a salutary barrier against the progress and the propagation of syphilis. Italy has adopted for Turin and Florence the regulations of Brussels. In Prussia the tolerated houses, which were at one time suppressed and then re-established, have been in the height of their vigour since 1855 under a similar "office of morals." In Holland, the municipal authority has established, since 1856, a very regular and severe inspection, instituting a communion to restrain the propagation of the syphilitic contagion, and forming registers for the inscription of young women.

But, precisely because we consider prostitution as a necessary evil, in populous cities and in seaport towns, and because we object to its being abandoned to itself, do we desire that governmental and municipal authorities should lessen the consequences of this social plague by causing sanitary laws to be scrupulously fulfilled, and by chastising severely the abuse into which women giving themselves up to this sad trade run.

Dr. Machucho, therefore, begs the attention of the civil governors of the province to reform immediately the interior rules of the tolerated houses in Spain. The tolerated houses in Madrid are in the greatest state of disorder, and are a constant menace to the health of the incautious and the morality of families. Cases of syphilis are very frequent, and offences against morality become multiplied. Scarcely can we walk a step at certain hours in the most central streets, without being detained by infected and impure women. These abuses should not be permitted in a city like Madrid. Modern societies authorise prostitution in tolerated houses, in order to avoid the scandal of the street. In Madrid there are numerous prostitutes before the age of puberty. The civil magistrate ought severely to punish abuses such as these, which, besides degenerating the human race, are a constant danger to

morality and public hygiene. To correct so many evils, it is indispensable, says Dr. Machucho, to establish a law, in which the following bases shall be adopted, and which have been advised by the most eminent physicians and hygienists: 1st. To inscribe in all parts of the kingdom of Spain women who give themselves up publicly to prostitution. 2. To visit them twice a week, using the speculum in every examination. 3. To admit venereal patients into general hospitals. 4. To establish public dispensaries for poor persons with venereal disease. 5. To prohibit in an absolute manner all provocation in the public streets. Under no pretext ought prostitutes to be permitted to use words, actions, gestures, openly provocative of prostitution.

Dr. Machucho adds that in spite of the salutary and profound respect for individual liberty entertained in England, that country has not feared to restrict liberty in so far as prostitutes are concerned. By a law promulgated in September 13th, 1866, England has conceded the right to submit to medical visitation during a year, all women accused of giving themselves up notoriously and habitually to prostitution. He adds that the said law is applied merely to ports and cities with garrison towns; but it is probable that it will be extended to all England, since it has gained the appliance of the scientific English press, from its having produced such excellent results. In Plymouth, for instance, the proportion of venereal disease in the English marine has fallen from the proportion of 7 per 100 to 2 per 100.

Vaccination.

A physician of Alencon, M. Damviseau, proposes with regard to the important question of revaccination, as a better guarantee of preservation, after vaccinating children to revaccinate them the week following with lymph from their own pustules. He asserts that the second vaccination has frequently given results, whilst the third has failed. He acts in the same way with adults when he revaccinates them.

Correspondence.

BABY FARMING AND LADY WRITERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The long communication of a lady signed A. B. (All Balderdash?—) inserted in *The Times* is so unreal that no one would pay attention to it, were it not that A. B. casts a reflection upon our profession which demands remedying if real, and further explanation in any case if imaginary. A. B. writes of a medical man with an obtrusive brass-plate on his door, who takes his chance of practice with his brother Medicos, upon whom she called, and who "cheerfully" agreed to alleviate the lady's troubles, or have her taken care of, when the time of parturition arrives, and the child *adopted*. The fee, A. B. tells us, required, was some £50 or £60. "As he was a public practitioner, I *fancy* he was *duly qualified* by a degree from some college, *and very possibly holds a respectable position in his neighbourhood*." Again: "But it is not a pleasant thing to think that a regular doctor could not only lend himself to such lucrative wickedness, but actually court it by advertisements in a daily paper." I ask A. B. in all seriousness, to name this gentleman, and send you in confidence his address, that you may judge of the reality of her letter. As it is I believe A. B. to have merely written that which is the effusion of a fertile imagination, and I will not believe that any *qualified* member of our noble profession would stoop to such wickedness and dangerous infamy, or lend himself to becoming an abortion-monger for a paltry £50. If A. B. gets her little kitchen maid, after great persuasion, to do dirtier work than is to be done in her scullery, and gets her own worthy self up in a style only to be equalled by the men, Park and Boulton, to simulate pregnancy, I sympathise with her in not recording her experiences, until the subject becomes sensational and well nigh exhausted, and fashionable. I allow Baby Farming to be one of the disgraces of the age, but would not permit A. B. to traduce our profession, without asking that the name of the medical man alluded to be divulged; if guilty he must be removed off the *Register*, but if he be no more than an imaginary character, I demand explanation for our brethren's sake.

W. C. D.

Medical News.

Royal College of Physicians, London.—At an Extraordinary Meeting of the College on Monday, the 18th inst., the following Gentlemen, having conformed to the by-laws and regulations and passed the required examinations, were granted licences to practise physic, including therein the practice of medicine, surgery, and midwifery:—Thomas Allen, King's College Hospital, W.C.; John Bateley, M.R.C.S., Southtown, Great Yarmouth; William Frederick Butt, M.R.C.S., 12 South street, Park lane, W.; William Bowen Davies, M.R.C.S., 15 Edmund Terrace, Cornwall road, W.; David Henry Goodsall, M.R.C.S., St. Mark's Hospital, City road, E.C.; William Hodges, M.R.C.S., 12 Ashley road, Bristol; George Millson, Donington, Spalding; William Price, M.R.C.S., University College Hospital, W.C.; Arthur Raynor, M.R.C.S., 16 Warden road, Kentish Town, N.W.; Tom Robinson, M.R.C.S., London Hospital, E.; Wm. Wilberforce Smith, M.R.C.S., 20 Bishop's road, W.; Henry Banks Spencer, M.D. St. And., High street, Oxford; William Bezley Thorne, M.R.C.S., 38 Upper Baker street, N.W.; Peter Vincent Timothy, M.R.C.S., 72 Worship street, E.C.; Edward Willis Way, M.R.C.S., Adelaide, South Australia.— The following candidate, having passed in medicine and midwifery, will receive the College Licence on his obtaining a qualification in surgery recognized by the College:— Charles Holmes, 46 Ogden street, Ardwick, Manchester.

Charing Cross Hospital.—The annual distribution of prizes to the Students of the Medical School attached to this hospital took place on Monday afternoon in the Board-room of the hospital. Dr. Stanley, Dean of Westminster, presided. The prizemen were as follows: — Llewellyn Scholarship, Mr. Noakes; Golding Scholarship, Mr. Chittenden; Gold Medal, Mr. Noakes; Senior Anatomy, Silver Medal, Mr. Lea; Certificates of Honour, Mr. Taylor and Mr. Crouch; Junior Anatomy, Bronze Medal, Mr. Hartley; Certificates, Mr. Orwin and Mr. Stephens; Senior Physiology, Silver Medal, Mr. Lea; Certificate, Mr. Chittenden. Junior Physiology, Bronze Medal, Mr. Gray; Chemistry, Silver Medal, Mr. Leeds; Certificate, Mr. Couldrey; Senior Medicine, Silver Medal, Mr. Walkers; Certificate, Mr. Noakes; Junior Medicine, Bronze Medal, Mr. Routh; Certificate, Mr. Lea; Senior Surgery, Silver Medal, Mr. Noakes; Certificate, Mr. Burroughs; Junior Surgery, Bronze Medal, Mr. Routh; Certificate, Mr. Lea; Botany, Silver Medal, Mr. Whitelam; Certificate, Mr. Taylor; Materia Medica, Silver Medal, Mr. Lea; Certificates, Mr. Whitelam and Mr. Chittenden; Midwifery, Silver Medal, Mr. Burroughs; Certificates, Mr. Noakes and Mr. Leigh; Forensic Medicine, Silver Medal, Mr. Leigh; Certificate, Mr. Weston; Pathology, Silver Medal, Mr. Leigh; Certificate, Mr. Hanson; Practical Chemistry, Silver Medal, Mr. Lea; Certificate, Mr. Champneys.

The Opponents of the Contagious Diseases Acts.—Whatever opinions may be held as to the policy of the Contagious Diseases Acts, there can be very little difference as to the justice of Lord Henry Lennox's denunciation of the style in which the opposition to them has been carried on. Never, perhaps, during the present century has a mass of literature so utterly obscene been forced upon decent people as the mountains of tracts, memorials, and handbills thrust into the hands of women and unmarried girls by the opponents of the Acts. Mr. Gladstone having intimated the willingness of the Government to grant an inquiry into the working of these laws, it is difficult to understand in what way the circulation of these handbills and memorials by the Anti-Contagious Diseases Acts Association can be justified. The credit or discredit, whichever it may be, of passing these Acts, belongs to no one party or class of persons; and they have indubitably effected some valuable sanitary and moral results in the districts where they have been enforced. But the cost of any such reforms may be too great; and, if the objections are valid, they can be best urged before the impartial and skilled tribunal of a Royal Commission. The present appeals to fear, or to worse feelings, deserve unqualified condemnation.—*The Standard*.

Parliamentary Intelligence.

HOUSE OF COMMONS.—July 20th.

CONTAGIOUS DISEASES ACTS REPEAL (1866 1869).

When Mr. Jacob Bright moved the repeal of these Acts last Wednesday, the house was cleared as on a former occasion. A good deal of what passed never, however, transpired, and the following is a condensed summary of the main features of the debate.

Mr. Jacob Bright said, the Contagious Diseases Acts had been smuggled through the House without an opportunity having been given to hon. members to discuss the measure. The same course had not been taken in the other House of Parliament. The Press had not criticised the Act with all materials necessary for doing so, and some papers had refused to insert replies to articles they had published on the subject. No witness had been called for the Crown that was not a paid official and a tool of the Act. Bishops had supported it, and now there was an association whose object was to extend the Act to all the women of England. It was to the interest of the police employed under the Act to prove cases. The association to which he had alluded had its objects to serve, and the Chancellor of the Exchequer was required to expend money to protect British husbands in the commission of adultery. That as regarded the army, we had never suffered from the physical weakness of our men, though we had sometimes suffered from the mental weakness of our commanders. He would not argue the question on sanitary results. A voice was heard from the country against the Bill in spite of the conspiracy of the Press. By what process did the law work? By that of spies, who dogged the steps of poor ruined women, and who entered poor men's houses and insulted the women. Class legislation had never been so put in force. The women taken up under this Act had not even a chance before the magistrate, for they were induced by fraud and cajolery to sign a voluntary submission. The fraud and cajolery were sanctioned by the War Office. He made that statement with deliberation. If a woman refused to place herself in the power of the police, she was bullied. We locked up those persons in order that they might have the ministrations of the gaol chaplain. Better to lock up some of those who defended the Acts. Prostitution had been legalized in England. The law had changed sides, and we were in partnership with houses of ill-fame, and, by sanitary care, prostitution was made attractive.

Lord Henry Lennox said, having listened to the speech of the hon. member for Manchester, especially to that part of it which related to the results of the Albert Hospital at Devonport, he could not remain wholly silent, seeing that, while acting as Secretary to the Admiralty, he had personal knowledge of the details of the working of that institution. The hon. member for Manchester had challenged the House on two points—first of all he had denied the beneficial working of the Acts, and, secondly, he had denied the moral benefits flowing from them; but he hoped to give a categorical answer to the hon. member on both of those questions. He declared that, so far from there having been any insufficiency in the degree of publicity given to those views, on the contrary, he deeply regretted the extent to which their publication had been carried, and also the manner in which and the means by which it had been accomplished. (Hear, hear.) For the last few months every day and every hour respectable households had been invaded by pamphlets and statements couched in the most filthy language and containing the most indecent details. Talk, indeed, of the want of publicity—he knew as a fact that in the county in which he himself lived, the drawing-rooms and breakfast tables of the wives and even the maiden sisters of the most respectable families had been deluged with publications which deserved no other fate than to be brought under the provisions of Lord Campbell's Act. Another complaint of the hon. member, to which he had listened with equal astonishment, was that those Acts had been passed without any debate in that House. Whose fault, he would ask, was that? When those Acts were introduced they went regularly through all the various stages through which all other legislative measures passed in the ordinary course. As to the beneficial working of the Acts, which the hon. member for Manchester had denied, quoting some figures given by Mr. Wolferston, the house-surgeon, to prove that during a certain period the number of women admitted to the Albert Hospital at Devonport had increased, and from that, forsooth, the hon. gentleman proceeded to argue that prostitution in that town had increased. He begged to assure the hon. member for Manchester that he had taken an entirely erroneous view of the inference to be drawn from those figures, the truth being that the increased number of admissions was owing to the increased knowledge spread among those unhappy women of the great benefits which would accrue to them from being treated in that hospital. The hon. gentleman also denied that those Acts had any result. Now, having himself, when Secretary to the Admiralty, moved for a vote of money for the erection of the Admiralty wing of the Albert Hospital, he told the hon. member, from an official experience of three years, that the reason why the results of those Acts had not been more satisfactory and complete was the limited area over which they operated, and the comparatively limited sums which had been expended in carrying them out. The really beneficial effect of those Acts, the noble Lord contended, could not be properly appreciated from the present system of partial treatment, as that disease required, like all other diseases of the same kind, a policy, so to speak, of stamping out to be applied to it. He also mentioned that at Sheerness, in the year 1867, the Admiralty received official intimation that the disease had then been all but completely stamped out. The hon. member for Manchester, referring to the Devonport Hospital, had stated that 500 women were annually driven up, forced, bullied, and compelled even by fraud in high places to enter those institutions. Now, he begged leave, speaking from official knowledge, to give his most positive contradiction to that statement, and to say that, so far from force, bullying, or official fraud being required, those wretched women flocked up, anxious to enjoy the benefits of the hospital, and fearful of nothing but the jeers of the companions whom they had left outside.

In that hospital at Devonport those unfortunate women were not only cured of a loathsome disease, but during their cure received the ministrations of the chaplain, were taught those first principles of religion of which when admitted they were supremely ignorant, and were practised in all those kinds of domestic and household work which when they left the institution would enable them to earn their living without returning to their former career of degradation. In conclusion, he really could not allow the erroneous statements of the hon. member for Manchester to pass without rising to implore the House to pause in its condemnation of a measure which he believed was calculated to promote the best social and moral interests of the country. (Cheers)

Mr. Whitbread thought there was nothing morally wrong in contributing to the maintenance of hospitals for contagious diseases. Measures ought to be taken to diminish the evil as much as possible, but he thought that severity on the part of the police would not conduce to that result.

Captain Vivian did not think that the opponents of the Acts had adopted a wise course. Mr. Garth Wilkinson's pamphlet, which had been distributed that morning at the houses of hon. members, was a filthy production, and contained a letter purporting to have been written by a lady which he would not characterize. He denied that the Contagious Diseases Acts had been smuggled through that House. There had been committees of that House on the Bills in 1864 and 1866. The voluntary system had entirely failed. Objections had been taken to every sanitary measure passed by the Legislature. How was it that so many of the clergy were in favour of the Acts now so much condemned by those who had got up the agitation against them?

He then proceeded to read a number of extracts from reports of persons who had seen the working of the Acts and believed them to be beneficial.

The debate was adjourned.

HOUSE OF COMMONS.—Thursday.

BRITISH MILITARY SURGEONS.

Major Anson asked the Secretary of State for War whether he intended to request permission for a British military surgeon of experience to be attached to the head quarters of the French and Prussian armies for the purpose of studying and reporting upon the effects of the more recent inventions of modern warfare, and the most approved methods of transporting sick and wounded men during rapid movements of troops.

Mr. Secretary Cardwell replied that the Army Medical Department attached great importance to the suggestion of

his hon. friend. He also recognised its importance, and should be glad to have the opportunity of carrying it into effect. In answer to a question of which he had received private notice, he might state that in laying down a general rule that military officers should not be permitted to attend the armies of foreign powers as correspondents or otherwise, her Majesty's government adhered to the course which had been pursued on former occasions. He was aware that exceptions had sometimes been made, but in the present case the government had resolved to adhere to the general rule.

HOUSE OF COMMONS.—Monday, July 25.

MEDICAL ACTS AMENDMENT BILL.

This Bill was to have been brought forward on Thursday last but the pressure of other business in consequence of the alarming state of affairs on the Continent compelled the Government to postpone it until Monday last. During that interval much extra pressure was brought to bear on the Government in reference to the 18th Clause and the constitution of the Medical Council. The representatives of the British Medical Association and of several colleges were occupied the whole of the time in urging their views, and Dr. Waters, as chairman of the Representation Committee, was particularly active.

The Bill we lately announced as to be brought forward, was held over in order to unite the whole forces of the Opposition, all parties being determined, if the Government would not yield, to support Dr. Lush, who had given notice that he would move that the Bill be read again that day three months. It then became evident to many that the Bill must be postponed, and when on Monday morning the *Times* published a project of treaty between France and Prussia, those who know the work of Parliament felt assured that the Government would have no time on their hands to force on a reluctant and indignant Profession a Bill in which the public had never manifested the least interest.

Accordingly, those who were present, in case of any such attempt, had the pleasure of hearing Mr. Forster state that he was under the necessity of withdrawing the Bill, as it was impossible, at this period, and under present circumstances, to deal with the constitution of the General Medical Council.

Having kept open our columns to a late hour in order to chronicle the debate, should any take place, we rejoice to be able simply to record the failure of the Privy Council to inflict a great injury on the Profession, and to congratulate the consistent opponents of the worst Medical Bill ever framed on the success of their unwearied efforts to secure its rejection.

THE CONTAGIOUS DISEASES ACTS.

Our Parliamentary Intelligence contains a full summary of the debate in the House of Commons on this subject. As our own columns have lately contained many letters upon one side, we were much gratified in inserting Dr. Waring-Curran's on the other. At a late hour we have received the following remarks in reply by Dr. Drysdale :—

It always gives me great pleasure to hear Dr. Waring-Curran's opinion on such subjects as the above. The boldness and originality of his views on many medical topics is well known to most of the readers of your enlightened and most liberal of all medical journals in this country. I understand Dr. Curran to say that the Irish people are "the most virtuous people in the world." Now, I do not venture to dispute such an assertion, or, indeed, to give any opinion on such a difficult matter ; but, in scientific journals I sometimes wish we had the power of arguing before hand upon the definition of a term we are about to make use of. Some persons, known as *utilitarians*, or followers of the School of Bentham, define virtue, or morality, that conduct which tends to make mankind happy. I fear that if that definition were adhered to Dr. W. Curran would have to prove to me that a country I have so much respect for—Ireland—has, during this century, been more happy than France, where, according to his standard (whatever that may be), the people are not so virtuous as the inhabitants of Ireland. Does Dr. Curran mean by virtue, perhaps, chastity ? Are the words synonymous in his opinion ? If so, I dare say many would say yes to his query—"Is there a more virtuous people in the world." Alas ! Mr. Editor, human nature is such a puzzle to us all, that we find that even the ideal chastity of Ireland has not prevented an amount of human misery and suffering in that country, perhaps unequalled in any European State in the 19th century. Prudence in the matter of numbers is, in the opinion of many, a *sine qua non* of virtue, and this element, virtue, and prudence, is common in France, although M. Lefort's letter startles us by his disclosures as to the practice of the Parisian working men and women. I saw it stated in a journal the other day that the French peasants "habitually limited their families to two children." They are either virtuous or not virtuous in such customs ; but in so far as they are virtuous in this, according to the standard of the utilitarians, or of the modern school of philosophy, there clearly must be something wanting in the ideal of the country which Dr. W. Curran calls the most virtuous in the world, if that ideal leads so frequently to overcrowding and difficulties of all kinds. I have long been rather inclined to look upon the French as in some respects (except in their love of war) the most civilized of all modern nations, and I merely write this note in reply to Dr. Curran's most admirable remarks, to show that I am not quite sure that I hold the same standard of right and wrong with him, unless, indeed, he will explain to me what his is. Dogmatic standards of morality, whether derived from one body of men or another, are rarely satisfactory to medical thinkers. No body of men are so likely to see what is true to nature in a question of right and wrong, and whatever they may be obliged, by the *res augusta domi*, to profess outwardly as to their tenets of morality, there is in my experience, no body of men so able to see to the bottom of such questions as that of Contagious Diseases Acts, or other intricate problems as our medical fraternity.

For my part I am entirely opposed to the English or French Contagious Diseases Acts, or anything approaching to them, because they are nostrums put forward to cure an inveterate disease, arising out of our backward state of theory in the matter of sex-contracts. They have done very little good in France (in my experience) in a sanitary point of view. That country is still full of venereal contagion, and I cannot help thinking that the carelessness of the working classes of Paris, spoken of by M. Lefort, with regard to their parental duties are, partly, at any rate, due to the unsensible teaching of the police Acts. Already in our garrison towns we find young men and faithless married ones, asking what day the women have been examined, and making use of this knowledge as a means of using what they would otherwise have refrained from—prostitution.

These were the points I suggested to our learned French professor, M. Lefort, and I added that it seemed to me that the irrevocable contracts, alone sanctioned by the French Church, were apt to add to the amount of prostitution, by encouraging, as they do, the life-long slavery of many persons in cases even of adultery and cruelty in their partners. Nothing that either he or your esteemed correspondent, Dr. Curran, has said, *as yet*, has changed my opinion. Besides, I hear from very high authority that greater facility for divorce worked very well indeed in Paris when it existed, and that it does so now in America in some States, in which States prostitution is almost unknown, although divorce is by no means common, notwithstanding its facility.

Gleanings.

Active principles of Gelseminum Sempervirens, with a Case of Fœtal Poisoning by three drachms of the Fluid Extract of the Plant.

Dr. Theodore G. Wormley, Prof. of Toxicology in Starling Medical College, Ohio, having been solicited to make an examination of the contents of the stomach of a woman who had died after taking the fluid extract of gelseminum, thought it necessary as a preliminary to institute a series of experiments in order to ascertain whether that substance, as prepared by Tilden & Co., contained any principle or principles by which its presence could be certainly determined. These experiments are detailed in the *American Journal of Pharmacy* for January, 1870, and they show according to Dr. G. that the fluid extract of gelseminum prepared by the above firm contains a new organic acid, which he names gelseminic acid, and a strongly basic or alkaloid principle, which, being the active principle of the drug, he names *gelseminine*, *gelsceminia*, or *gelsemia*.

The case of poisoning which instigated these investigations was as follows:—

"On the 30th of January, 1869, three teaspoonfuls of the fluid extract were administered to a young healthy married woman several weeks advanced in pregnancy, who at the time complained of no serious illness. In two hours after taking the dose, the patient complained of pain in the stomach, nausea, and dimness of vision. These symptoms were soon succeeded with great restlessness, ineffectual efforts to vomit, and free perspiration over the body. At the expiration of about five hours the pulse was found feeble, irregular, and sometimes intermittent; there was great prostration, with irregular breathing and slow respiration. The skin was dry; extremities cold; the pupils expanded and insensible to light; the eyes fixed and inability to raise the eyelids. The vital powers rapidly gave way, and, without convulsions, death occurred in about seven hours and a half after the poison had been taken.

"It will be observed that in this case, only three teaspoonfuls of the fluid extract were taken. Presuming it to have had about the same strength as the preparation we examined, the quantity of the alkaloid contained in this amount could not have much exceeded the sixth part of a grain. This would seem to indicate the alkaloid to be one of the most potent poisons at present known.

"*Post-mortem appearances.*—Eight days after death the body presented the following appearances, as described by Dr. J. H. Stephenson, who made the autopsy and to whom I am indebted for the account. Countenance natural as in sleep. No emaciation, and body in a perfect state of preservation. Cadaveric rigidity very slight. The back of the neck and between the shoulders, extending the full length of the spine, as also the depending parts of the thighs, and arm to the elbows, presented a congested appearance. The membranes and substances of the brain and medulla oblongata were normal. The adipose tissue remarkably thick, and highly tinged throughout with bilious matter. Lungs slightly collapsed, natural in appearance, and superficial veins congested. Heart normal in size, superficial veins injected, and the cavities greatly distended with dark grumous blood, inside of which was found a well-defined membrane, identical in appearance with that found in diphtheria and pseudo-membranous croup. The abdomen presented no tympanitic distension. Stomach slightly distended with gas, and contained a small quantity of ingesta. Peritoneum and intestines in a healthy condition. Liver and investing membrane normal; left kidney congested. The uterus was slightly enlarged and contained a fœtus of about five weeks' development.

"A small quantity of the contents of the stomach having escaped from the organ at the time of the dissection, was collected separately in a small bottle; the stomach with the balance of its contents was placed in a larger bottle. These bottles, with their contents, were carefully sealed and remained undisturbed until the 17th of May. At this time the contents of the bottle containing the stomach were found to have undergone considerable decomposition. A little pure alcohol was added to the decomposing mass, and it was then allowed to remain until the 13th of June, when the chemical examination of the contents of both bottles was commenced.

"*Chemical analysis.*—The contents of the *small bottle*, consisting of about two fluidrachms of liquid with a small amount of solid matter, were digested with about one ounce of strong alcohol, the liquid then decanted, and the solids washed with fresh alcohol, which was collected with that first employed. The alcoholic liquid was now concentrated at a moderate temperature to about one-half its volume, then filtered, and the filtrate concentrated to about one drachm of fluid. This concentration caused the separation of some oily globules, and also of some apparently vegetable solid matter, and the mixture exhaled a very marked vegetable odour, very similar to that of the extract of gelseminum under similar conditions.

"The concentrated liquid thus obtained was again treated with alcohol, filtered, and the concentrated filtrate treated with about half an ounce of pure water, which left considerable matter undissolved, and furnished, when filtered, a clear slightly yellowish solution. This aqueous solution was concentrated to a small volume, filtered, the filtrate acidulated with a few drops of acetic acid and then extracted with two volumes of pure commercial ether. On allowing the ethereal liquid to evaporate spontaneously, it left a nearly colourless residue containing several groups of crystals, similar in appearance to those of gelseminic acid.

"A portion of this residue, when examined in its solid state by nitric acid and ammonia, and another portion when dissolved by the aid of an alkali and the solution tested by several reagents, presented the chemical and fluorescent properties of gelseminic acid in a degree indicating the presence of a very notable quantity of the acid. The contents of the small bottle were not examined for the alkaloid.

"The contents of the *stomach* were treated and purified after the general method described above, and the final aqueous solution acidulated with acetic acid and extracted with ether, for the purpose of recovering the organic acid, if present; the solution thus extracted was then rendered slightly alkaline and extracted by chloroform, for the purpose of recovering the alkaloid. The purified ether extract revealed very satisfactory evidence of the presence of the organic acid, both in regard to its fluorescent and chemical properties. So, also, the chloroform extract, when purified and the final aqueous solution concentrated to a very small volume and examined by several reagents, furnished undoubted evidence of the presence of the base, indicating it, however, to be present only in very minute quantity."

On comparing the intensities of the reactions of the several reagents applied with those obtained by the same reagents from solutions of the alkaloid of known strength, it was inferred that the quantity of the base recovered in this case did not much, if any, exceed the fiftieth part of a grain. The quantity of the alkaloid originally taken, as we have already seen, did not probably much exceed the sixth of a grain.

The fact that the stomach with its contents had undergone considerable decomposition, and also that the chemical examination was not made until some months after death, would seem to indicate that the poison is not readily destroyed by decomposition, and that it may be recovered after comparatively long periods, even when taken only in small quantity.

Pleasant Item for Smokers.

A correspondent in New York writes us (*New York Medical Reporter*) of a young man who has been for three years the victim of constitutional syphilis of aggravated character. His lips and tongue are covered with mucous patches; a most offensive odour emanates from his whole body, especially from his breath, and a caries seems about attacking the bones of the nose, &c.

He is a cigar-maker by trade, and he has daily been making cigars since he was first attacked. No cigar is made without moistening the leaf with saliva, as every one knows who has ever seen a cigar made. Is it not more than probable that many who have smoked cigars of his make, and others similarly situated, have imbibed syphilitic poison, and then wondered how they got the disease?

Bromide of Potassium in Tetanus.

Dr. W. B. Fletcher, of Indianapolis, relates (*Indiana Journal of Medicine*) two cases of tetanus nascentium in which recovery followed the administration of bromide of potassium in half-grain doses after each convulsion. In one case forty grains were taken altogether, and in the other twenty grains in the course of forty hours. In both, the symptoms came on within twenty-six hours after birth, and in neither was there any abnormal appearance about the umbilicus; which circumstances militate against Vogel's view of the disease.

CONTENTS.

EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By G. A. Gordon, M.D., C.B.,

Deputy Inspector-General of Hospitals.

(Continued.)

It will be in the recollection of some readers of these notes, that when, about 1850, barracks according to a new and improved plan were erected at Mean Meer, near Lahore, a system of cess-pit privies was at the same time instituted in connection with that portion of the station occupied by the infantry.

These pits were carried down to the water-bearing strata, and were about fifty-eight feet deep, the intention having been to permit their contents to accumulate. Two of them were only 118 feet from a well, and others not much more distant. The stratum at that depth consisted for the most part of a bed of sand through which water seemed to percolate readily, and when in 1853–4 the 10th Foot occupied the station, contamination of the water of those wells was suspected. The presence of the pits had also become objectionable from the offensive emanations which arose from them, and became disseminated along the barracks. I at that time protested strongly against them; but not until eight years afterwards was any notice taken of my report on the subject, and then only when some of the evils I had predicted had actually happened; thus in the Report of the Commission appointed to inquire into the circumstances attending the terrible epidemic of cholera by which that place and others were devastated in 1861, opinions and views that had long previously been expressed by me were quoted by the Commissioners. They noted my remark with regard to these pits full of abominations, that "the stench from them was at times perfectly overpowering." They then add, that "in their Annual Report for 1853–4, the Medical Board quoted the opinion of Dr. Gordon, of Her Majesty's 10th Foot, to the effect that this abominable system 'was calculated, in the course of a few years, to induce epidemics of cholera and fever.'" Two years afterwards, namely, in 1856, a severe attack of cholera occurred among the troops there, there having on that occasion been 495 cases and 265 deaths in a strength of 1,592 British soldiers. On the last named occasion, namely, in 1861, the water from the wells in question was examined by the chemist at Lahore, who expressed his opinion that "in some instances, at least, contamination had actually taken place;" but in illustration of the remarks already made, it should be stated that although on the occasion of the great epidemic at Mean Meer the ravages of cholera were greatest in the 94th Regiment which occupied the barracks nearest to the cess-pits, and to the contaminated wells, yet the first outbreak of the disease did not take place there, but in the 51st Regiment, then occupying a part of the Artillery lines at the opposite end of the station, and at such a distance as to put all possibility of the water there being affected out of the question.

To summarise as briefly as possible some of the conditions under which cholera may occur, I would enumerate the following, namely:—

1. It may take place in isolated cases or localities.
2. In a succession of partial or local outbreaks.
3. In bursts of epidemic, devastating stations and districts in a definite course.
4. As similar bursts; but to spring, as it were, over places to attack those at a distance.
5. As affecting the occupants of certain parts of a town, station, or building, while others, apparently precisely similarly situated, escape.
6. From the operation of certain medicines, more especially drastic or saline purgatives, and from violent emetics.
7. In intermittent fevers, in some cases of dysentery, and in some other diseases.
8. In localities where it most constantly prevails endemically it less frequently occurs as an epidemic than it does in such as are at certain seasons completely exempt from it.
9. The presence of decomposing animal matter, more especially in the soil, as in cesspools, drains, cemeteries,

&c., undoubtedly act under certain other conditions and at times as sources whence cholera may reasonably be believed to arise. At other times, and under other conditions, no such results occur from the presence of such matters.

10. Doubtless, water containing matter of cholera dijection, and that containing decomposing animal matters, frequently produces cholera in those who use it. It does not, however, do so invariably, or *necessarily;* and, as epidemics of the disease travel more frequently upwards along the course of the Ganges than downwards, the theory of water contamination is not sufficient by itself to account for the occurrence of the disease.

That cholera, in very many cases, utterly defies all treatment must, unfortunately be acknowledged; and, perhaps, this fact taken in connection with the terrible virulence with which, in the majority of instances, the first onslaught of the disease in epidemic form takes place may, in part, account for the little confidence felt by many persons in medicine in such cases, as well as the unscientific and empirical nostrums to which recourse has, in too many instances, been had, to the neglect of those principles of physiology and therapeutics according to which members of the medical profession usually treat maladies they are called upon to combat.

Of this want of success in the treatment of cholera non-professional men are not slow to take advantage, to the discredit of the science of medicine generally. This remark is simply illustrated in the report of the Commission regarding cholera in Northern India in 1861. In that report (page 251) we read that "almost every report of every medical officer tells the same story of hopeless failure in the attempt to combat the disease in its advanced stages;" that "not only did every remedy appear useless, but we have found a strong doubt prevailing in the minds of some of the most thoroughly competent of the medical officers whether the practical result of the existing systems of treatment has not sometimes been a positive aggravation of the mortality;" and again,—"In many instances (page 252) I imagine that the patient dies of the doctor rather than of the disease so long as we know nothing of the nature of the disease, and so long as we have the most opposite modes of treatment vaunted in their turns—how can it be otherwise?" and then they quote, exultingly, the remarks by Dr. Elliotson when treating of the disease in England. "If," said he, "all the patients had been left alone, the mortality would have been much the same as it has been."

It must, I fear, with deep regret, be acknowledged that these remarks have very considerable foundation. I could enumerate a variety of so called systems of treatment, and of individual empirical remedies, the *modus operandi* of which put all ordinary principles at defiance. For examples I would allude to such measures as the injection of saline mixtures into the veins of persons affected with this painful malady to the neglect of all other means; to the application of cauteries along each side of the spine from the nape to the sacrum, at the same time that the cravings of the patient for cold drinks were tantalised by the occasional exhibition of spoonsful of warm water gruel. We next find that a plan was recommended of aggravating the vomiting, which is one of the most painful accompaniments of the disease, by the administration of large quantities of mustard: while some persons, acting apparently according to still more dangerous views, prescribed tartar emetic, as if with the object of accelerating the vital depression which the disease by itself was sufficient to lower to the utmost, or completely destroy. Space will not permit me to enumerate all various methods of *treatment* that have been from time to time adopted in this disease. I may, however, mention the administration of Epsom salts and tartar emetic combined; the free use of water internally, sometimes hot, sometimes cold; the affusion of cold water, partially or to the whole body; the complete withholding of all fluids; the administration of such agents as carbonate of soda in five-grain doses at long intervals; the employment of *jactitation* so as almost literally to *shake the life out* of the patient; and, perhaps, most horrible of all, the application of mechanical means to prevent discharge of the intestinal flux. As a further illustration I would mention the following case which came under my notice so lately as 1866 in Calcutta:—

A soldier of the Rifle Brigade, then in Fort William, having been admitted into hospital suffering from intermittent fever, he, during accession of the cold stage of that disease, passed into decided cholera, and was treated by a recently arrived assistant-surgeon, whose scientific acquirements were described as being of a very high order. On visiting the patient some time afterwards I found him approaching a state of collapse, *notwithstanding* that he had received the following treatment:—A scruple of calomel had been administered on the accession of the choleraic symptoms; a bottle of champagne had then been given, after which he was treated by solution of permanganate of potass in frequently repeated doses. I remonstrated, but was informed that the object was to supply oxygen to the blood, that the solution, when vomited by the patient, was quite *brown*, indicating thereby that it had parted with a portion of its oxygen, which must thus have been supplied to the system. The method of treatment was changed on the spot, and the patient subsequently recovered; but I look upon the case as illustrating the theoretical views according to which this formidable disease is, it is to be feared in too many instances, trifled with.

In alluding to some remedies used in accordance with more scientific principles than those above enumerated, I would specially refer to venesection, calomel, and opium.

At one time the employment of venesection, when practicable, was in common use, and in some cases advantage seemed to be obtained from it; as a rule, however, it was impossible to abstract blood, partly from the circumstance of the circulation being so much enfeebled, and partly from the condition of the blood itself, so that this method of treatment was set aside as untrustworthy. Calomel, it is almost needless to observe, was given alone as well as combined with opium, sometimes in large doses, sometimes in small, but always with the double object of acting as a sedative and stimulating the flow of bile. How far either effect was ever produced was doubtful many years ago, although probably medical officers hesitated much before abandoning what was then the *orthodox* treatment, and more recent researches into the action of mercury tend to indicate that their doubts were well founded. So with opium: the necessity for, as well as benefit to be derived from, its employment had been questioned. In 1843-4 it was found that among the men of the *Buffs* at Allahabad, *secondary* fever or, in other words, cerebral affection supervened in every case in which it had been administered largely, the mortality from that complication being larger in proportion than during the primary attack. The use of opium was accordingly abandoned in the hospital under my charge, and with favourable results, nor was it again used by me in subsequent regimental practice in India.

In briefly narrating the treatment adopted for cholera in the *Buffs* and in the 10th Foot, it may be well to allude to the theory according to which our remedial measures were directed. Whatever may have been the nature of the influence upon which the disease ultimately depended, the tendency of that influence acting upon the human body was to produce death; but practical experience had shown that in those cases where the vital powers were maintained sufficiently long by the employment of artificial stimulants or other means, those powers recovered their natural condition—slowly, and probably with interruptions, yet to such an extent as to constitute recovery. Bearing the above indications in view, then the following routine was that pursued, namely:—

1. To relieve the nausea, vomiting, and sense of sinking which characterised the first onslaught of the attack, carminatives, stimulants, and antispasmodics were ad-

ministered, as for example, a combination of the ethers, aromatic ammonia, tinctures of capsicums, ginger, and so on; sinapisms being, meantime, applied to the epigastrium. It is almost needless to observe that the earlier in the attack these remedies were employed the greater was the chance of success; and that whenever the disease was prevalent, arrangements existed by which soldiers attacked in barracks might immediately obtain medicine of this description.

2. The intestinal flux being looked upon as a flow of serum, dependent upon causes affecting the system generally, we considered that this indication should best be met by remedies directed to supporting the general powers instead by those of a more special nature, such as direct astringents. Those, therefore, which were applicable to the indications first enumerated were held to be so to this.

3. In those cases, and they are numerous, in which vomiting is persistent, notwithstanding the use of remedies ordinarily employed, diluted prussic acid in combination with the medicines already mentioned, was followed by such favourable results as to justify a further trial being made of it. As an adjuvant, counter-irritation was employed to the epigastrium, either by means of a blister, or by the instantaneous application of a cloth dipped in sufficiently hot water to produce vesication.

4. To maintain warmth of the body as far as practicable, hot bottles, protected by flannel, were applied wherever most required. The surface was wiped with soft cloths, and kept warm as far as possible; but, as is well known, the coldness of the body and limbs of a patient affected with cholera, and which seems to have no reference to the season of the year, or state of atmospheric temperature, is only checked when circulation begins to be re-established.

5. The spasms which pervade the limbs were usually met by frictions, or by "kneading" the parts most severely affected.

6. The intense thirst which attends the disease is perhaps best moderated by the administration of ice; by brandy and water, alone or in effervescence; while the same stimulant in sago, whether hot or cold, was in many instances relished by the patients.

7. Regarding the suppression of urine which attends the disease, it was customary to look upon the cessation of that symptom as an indication that the functions of the organs were being restored by the treatment already mentioned.

I would further observe in this place that, after experience in the treatment of the disease had been gained, we learned that although, as already stated, secondary fever almost to a certainty followed, after opium in large quantities had been administered, provided the patient survived the first onslaught of the malady, this complication, under certain conditions, also happened where no opium had been given. In either case, the affection was preceded by the occurrence of constipation, and was most surely averted by the employment of carminative laxatives, more especially in the form of tincture.

It need hardly be repeated that my purpose is not to give a systematic treatise on cholera. All I aim at is to communicate such of the results of my own experience of the disease as are likely to be useful to other medical officers; and with this view I would submit the following cases:—

Hally, 10th Foot, admitted at Dinapore on 22nd August, 1857, suffering from the ordinary symptoms of cholera, attributed by him to exposure and the *use of bad water* while employed against the rebel sepoys in the jungles of Jugdespore. The symptoms were of an aggravated kind, but had not passed into the stage of collapse. A draught, composed of aromatic spirit of ammonia and sulphuric ether, of each twenty drops, and ten drops of tincture of capsicum was administered, and repeated every half-hour. Vomiting being obstinate after several doses of the mixture had been given, three drops of medicinal hydrocyanic acid were added, and the whole given in ℥jss. of camphor mixture. Mustard was applied to the epigastrium, and hot sago with brandy given. This treatment was continued throughout the 23rd, during the night of which all the symptoms moderated except the vomiting, and it still continued obstinate. According to the morning report of the 24th, natural warmth of the body had been restored. On the 25th the report stated that the choleraic symptoms were disappearing; but that the patient experienced a feeling of "fulness in the head," for which a draught was administered, consisting of ℥j. of tincture of jalap, ℥ss. of confection of senna, carminatives being continued at intervals. The improvement in his condition continued until the night of the 27th, during which he began to become cold again. Stimuli were immediately given, and hot bottles applied to the hands and feet. Under this treatment the temperature became re-established, and improvement was steadily progressive, no further treatment being administered beyond tonics of gentian and quinine; the bowels being regulated by the laxative as above. On September 7th he was discharged to duty, having been sixteen days in hospital.

(To be continued.)

CANCER OF THE LUNG.

By Arthur Leared, M.D., M.R.I.A.,
Senior Physician to the Great Northern Hospital.

Cancer of the lung is a disease of sufficiently rare occurrence to make the following case worth recording:—

An agricultural labourer, sixty-eight years of age, was admitted into the Great Northern Hospital, May 29th, 1869. He was a man of spare build, and stated that he had been always healthy until about two months previously, when he began to suffer from cough and oppression at the chest and to expectorate blood. Before coming to the hospital he had been under the care of Dr. Barrington of Bexley Heath, and he had also been for some time an out-patient at St. Bartholomew's Hospital.

His state on admission was as follows:—He was thin and feeble, voice very weak, aspect that of hectic fever, rather than of malignant disease, pulse quickened, decubitus on the left side. He complained of pain in the right side of the chest, and had a troublesome cough. The sputa were copious, viscid, blood tinged and had an offensive smell.

On the right side in the space between the clavicle and the lower edge of the second rib tenderness on pressure, complete dulness on percussion, and absence of respiratory sounds were observed. Vocal fremitus was not affected. Below the second rib the breath and percussion sounds were normal. Posteriorly on the same side a tumour which had been first noticed a week previously, of the size of half a goose's egg was seen bulging from under the scapula. The long axis of the tumour which encroached upon the edge of the axilla was perpendicular and extended two inches lower than the dulness anteriorly. The tumour was slightly tender on pressure, of firm consistence and perfectly dull on percussion. The intercostal spaces below the tumour were normal. No enlarged glands could be detected anywhere. The patient attributed the tumour to having strained himself by working at a straw-cutting machine. The diagnosis was cancer of the lung with continuity of growth between the cancerous organ and the tumour.

On June 4th the anterior dulness extended downwards to the upper edge of the third rib, and hæmoptysis was increased. Three days later the dulness on percussion extended downwards to the lower edge of the third rib. Cough more troublesome, but less hæmoptysis. Six days afterwards the anterior dulness had made no progress. The patient had of late been obliged to sleep well propped up, and he was failing in strength. Three days from this

date hæmoptysis to a considerable extent occurred, and his right hand and arm were œdematous. The anterior dulness was unaltered. Eight days still later he was in every respect worse ; the anterior dulness extended to the upper margin of the fourth rib, and the tumour was considerably enlarged. On the fourth day afterwards he died from exhaustion.

Post-mortem Examination—The body was emaciated, while the right arm and forearm were very œdematous. The skin over the tumour, which was the size of half a cocoa nut, was of natural colour, and no dilated veins were anywhere noticed. The external edge of the right scapula was raised from its proper position by the tumour. By firm pressure near the anterior margin of the axilla, the ends of the second and third ribs were felt projecting as if broken off.

The right pleural sac was found to contain much serum. The lung bulged forward, and it was seen that two-thirds of the lung superiorly had been transformed into an encephaloid mass, which, from its intimate union with surrounding parts, it was impossible to remove from the body without disruption. The external tumour was ascertained to be formed by an extension of this mass, into which portions of the first, second, third, and fourth ribs had been, as it were, fused. The ends of the ribs, both anteriorly and posteriorly, were jagged at the points of severance, and irregular with regard to each other. The posterior end of the third rib in particular was not more than two inches from the spinal column.

The cancerous mass was white and pultaceous, breaking down very easily on handling. Under the microscope it was found to be mainly composed of small nucleated cells. It is worth notice that, while examination of the sputa during life yielded cells of the same character, they were considerably larger in size and their contents were of a darker colour, a circumstance probably to be attributed to the passage of the cells from the more saline fluid of the cancerous mass into the less saline fluid of the bronchial tubes. In the left lung nothing abnormal was discovered with the exception of a single deposit of a chalk-like substance, the size of a pea, on the external part of its inferior lobe. The heart, kidneys and the liver were normal, and no cancerous glands could be discovered.

Remarks.—The progress of the malignant growth was rapid, although intermittent. This was shown by the increased breadth of the zone on the anterior part of the chest, marked by dulness on percussion, and absence of breath sounds, and also by the enlargement of the tumour. In six days from the patient's admission this zone progressed from the lower edge of the second to the lower edge of the third rib. No progress was then made in this direction for several days, after which the growth was again active. Œdema of the right arm was plainly caused by obstruction of the axillary veins by the tumour. Pain was not an urgent symptom, but this is not unusual in visceral cancer. The absence of glandular enlargement and of dilated veins is worthy of notice. In some of its features, such as emaciation, night sweats and hæmoptysis, the case resembled phthisis. But the rapid infiltration of the lung, the pain, the side upon which the disease was developed—since cancer attacks the right more frequently than the left lung *—and above all the tumour pointed to malignant disease.

We are sorry to see that a member of the Profession in London has been summoned for an assault said to have originated in a refusal of medicine to a patient at a special hospital, who had paid five shillings for a ticket. Though the summons was dismissed with costs, it shows one evil that may arise from a system of taking money at special institutions. There are other evils besides, and the Profession will never like such charities ?

Hospital Reports.

EVACUATION OF FORTY-SIX OUNCES OF MATTER FROM AN ABSCESS WITHIN THE ABDOMEN, BY MEANS OF THE "ASPIRATEUR."

By Mr. Morgan, F.R.C.S.I., &c.,

Surgeon to Mercer's and the Westmoreland Lock Hospitals, Dublin. Professor of Surgical and Descriptive Anatomy R.C.S.I.

A girl, aged nineteen, unusually diminutive in her appearance, and not intemperate in her habits, who had previously been healthy, and had no previous evidence of any hepatic derangement after her admission to hospital, suffered for five weeks from all the symptoms of deep-seated inflammation of the right side of the liver, and finally became extremely exhausted and reduced in strength.

On July 18th, after careful examination, I found some slight evidences of fluctuation over the front of the liver, corresponding probably to the interspace between the two holes. The viscus itself was considerably enlarged, and extended to about midway to the umbilicus. The antero posterior enlargement was very striking and remarkable. The veins on the surface of the abdomen were enlarged, the blood current indicating an upward flow. As the evidence was still obscure, although the symptoms were tolerably urgent, I determined to wait a few days, to observe the further course of the abscess, as I was satisfied it was.

On the 21st July I found the fluctuation more evident, though deep-seated, and, as the patient was in an extremely critical condition, I determined on its evacuation, and passed for 2½ inches in depth into the abdomen and about 2 inches below, and the same distance to the right side of the xiphoid cartilage, the second largest sized trocar tube of the "aspirateur," and withdrew four ounces of thick, creamy, and fœtid pus. No more would then come away, and, under the circumstances, I did not like to push the instrument down its full length. The patient felt relieved.

On the 23rd I introduced the next sized tube, and withdrew ten ounces of the same kind of purulent matter, affording great relief to the patient, who slept, for the first time for some weeks, comfortably for the whole night.

On July 26th the evidence of matter in quantity being pretty well established, and finding the patient a little stronger, I introduced the second largest sized trocar and canula of the "aspirateur," and removed the enormous quantity of forty-six ounces of thickish, healthy-coloured, but fearfully fœtid, pus ; so intensely so, that three surgeons who were present, were obliged hastily to retreat. The fœtor was most intense, and was such as would be connected with an intestinal abscess. The pus was not tinged by blood, or bile, while the drawing away of the matter was followed by most marked relief—the patient sleeping well, and being free from pain, particularly that of distension and weight which was very distressing previous to the operation.

The ultimate success of the case it would be premature to regard as certain, but the relief afforded by surgical interference, and the evacuation of so large a quantity as forty-six ounces of pus from the abdominal cavity, were most remarkable; and would leave every hope that deep-seated abscesses in important viscera may be safely reached, much suffering saved, and valuable lives preserved, by this means of evacuation.

ARMY HOSPITALS.

Case of Abscess of the Abdominal Wall.

Reported by Surgeon Cullen, 71st Regiment, Curragh.

The history of this case, an abscess of the abdominal wall, the result of gonorrhœal buboes, opening into the

bladder, and discharging by the urethra for three weeks; then, the mode of exit proving insufficient, requiring external incisions for its relief; and, ultimately, a perfect recovery being afforded after prolonged treatment, appears, from its rarity, worthy of being recorded.

The patient, a robust-looking Scotch recruit, of dark complexion and healthy appearance, contracted gonorrhœa at the Curragh, 14th September, 1868, for which he was seven days under treatment. He was discharged apparently well, but on arrival at Gibraltar in October he was re-admitted for ten days to hospital with a return of his complaint. He was again discharged 1st November, and again made his appearance 8th November with suppurating buboes in both groins, and the urethral discharge as bad as ever.

He denied having exposed himself to any fresh infection from the time of his original admission at the Curragh.

The buboes were incised, but deep sinuses formed, especially in the right groin, and he was 118 days in hospital and 10 days convalescent before he was returned fit for duty with sound cicatrices.

During this prolonged treatment of six months his general health suffered very little.

He now went to drill for a fortnight, but came back to hospital 1st April, 1869, complaining of constipation in his bowels, not having had a motion for eight days, and describing a great difficulty in making water from pain in the right iliac and pubic regions.

There was distinct circumscribed swelling and hardness there, and over the bladder a tumour could be felt hard and resistent, much as if a turkey's egg were embedded in the deep tissues. The right groin again showed an open sinus, but this did not extend to any depth, nor was there any surrounding inflammation.

A catheter was passed without difficulty, and clean limpid urine, containing urates and phosphates, was withdrawn.

Fomentation was applied to the pubic region, repeated doses of castor oil and turpentine were administered, an enema was thrown into the rectum, and after a time a mass of dark hard lumpy fæces came away followed by more natural stools. The following day a dose of calomel, followed by castor oil, brought away more hardened fæces, and, to allay the tendency to flatulency which he exhibited, a few doses of soda and peppermint-water were given.

On the 3rd fomentation by spongio-piline was applied over the vesical region, and on the 4th the bowels were again acted on by means of black draught.

Up to the 15th the fomentation was continued, and the bowels and kidneys acted regularly, microscopic examination of the urine showing urates and phosphates as before. He took a bitter tonic, with acid hydrochloric dil., part of the time.

A blister was applied on the 15th over the region of the tumour, which occupied the right pelvic and adjacent vesical region, and had become denser and more circumscribed. On the evening of the 15th while straining to make water, he noticed that the clean stream of urine changed into a thick whitish turbid one, and that afterwards the prominence of the tumour had materially diminished.

Four ounces of urine were put aside, and this was found to deposit half-an-ounce of a white flocculent-looking sediment, which under the microscope proved to be entirely pus.

Up to the end of April the discharge of pus continued, averaging from one to two drachms in four ounces, and it was observed that the superficial and deeper connective tissues forming the walls of the abscess became gradually matted together. The bowels continued to require a purgative every third day.

On 4th May very few pus cells were observed in the urine, but the abscess had become tenser and fuller. It was punctured with a small trocar and one and half ounce of pus removed. No air was allowed to enter. The site of the puncture was about two inches above the pubes, and one inch to right of the middle line. Poultices were applied to the abscess, and he was ordered infusion of quassia with hydrochloric acid.

On the 5th and 6th the puncture was repeated; on the 7th, as the abscess was approaching the surface, an incision was made into it, and two and half ounces of thin pus removed. He was feverish on this date, but it passed off on taking an alterative of quinine and hydrarg. c. creta.

A pad and bandage were now adjusted over the abscess, which admitted a probe into its cavity for several inches laterally. He was allowed a liberal diet with malt, and in the course of three weeks the amount of discharge had diminished to half an ounce daily. The urine exhibited an extensive deposit of ammoniaco-magnesian phosphates, but no more pus cells were observed after the 7th May.

The closing of the abscess was very gradual, but all the tissues appeared thoroughly consolidated on his discharge 31st July, though some induration still exists in the track of the last open sinus, and there is fulness in the right abdominal wall extending up to the level of the umbilicus.

Case of Amputation through Shoulder-Joint, under the Care of Surgeon Porter, 97th Regiment.

Reported by Assistant-Surgeon R. E. Bredon, 97th Regiment.

Drummer J. S., 1st Battalion, 4th (King's Own) Royal Regiment, came to hospital on the 7th of July, 1869, complaining of pain and tenderness around the left shoulder-joint, and inability to use the arm. He stated that he had not received any blow or other violence to account for it. He received some local treatment, and was discharged in the evening apparently quite well. On the 9th he returned, with the symptoms he previously presented somewhat aggravated. He again was questioned as to any violence having occurred, and again denied it. A most careful examination for fracture or dislocation was made, but with negative results. The disease was then looked on as of rheumatic origin, a supposition supported by the fact that he complained of some pain in the præcardial region, though there were no stethoscopic signs to indicate the existence of any cardiac disease.

On the 11th the following was noted:—"Very much worse. There is high fever, rapid pulse, tongue furred, much thirst, restlessness, and some depression. The upper arm is extensively, and the forearm considerably, swollen, tense and red. The former is at least four times its natural size. The pain is very great, and is increased on pressure. It is most marked on the front of the shoulders. There is very much the appearance of deep-seated inflammation around the joint and bone." Small doses of calomel were prescribed, and the arm, after being scarified freely with a lancet, was wrapped up in a large poultice.

For the next few days the arm remained in pretty much the same state, though the constitutional symptoms became less decided. About the 13th a very erysipelatous-looking blush came over the forearm. A couple of free incisions skin-deep gave him considerable relief, and, under a more generous diet and the use of ammonia and bark, he seemed to be progressing fairly, though the arm continued swollen, and the hand became œdematous in a very marked degree. There was some puffiness of the feet.

On the 20th he is reported "not quite so well." There was much "bogginess" on pressure around the forearm, and in this situation on the radial aspect an incision was made which laid open a long sinus from which some thick pus exuded.

The shoulder was at this time much swollen, and apparently the joint contained a good deal of fluid, but no pain or uneasiness was referred to this situation.

21st.—The joint was swollen and very puffy looking. An incision was made with a lancet at a point a little

above the insertion of the deltoid, and from some depth in the tissues there came out a quantity—ten ounces at least—of thin purulent matter, mixed with cheesy agglomeration. A probe passed through the opening struck bare bone, which was believed to be the neck of the humerus. When the cavity had collapsed after the removal of the fluid, the head of the bone appeared to have passed out of its normal position, and the shoulder had all the appearance of one in which a dislocation of the humerus, downwards, forwards, and inwards, had occurred. It was also supposed that complete disorganisation of the joint had taken place. In the course of the evening at least twice as much more of the same sort of matter exuded from the opening.

On this day he complained also of some pain and swelling in the right knee-joint, to which accordingly strips of blistering-plaister were applied. There was still a good deal of œdema of the feet, but no albuminaria could be detected.

Late in the evening of this day (21st) it was decided to expose the head of the bone, and to decide the subsequent steps of the operation according to the condition in which it might be found.

On the 22nd, the patient having been placed under chloroform, the joint was examined with a bullet probe, and, as the humerus was found denuded of periosteum for some distance downwards, it was decided that amputation was necessary and excision impracticable.

A flap was made by transfixion from the outer part of the arm, consisting mainly of the deltoid muscle. The bone was then pressed outwards, and the internal flap formed in the usual way. There was no pressure made on the artery during the operation; but the principal assistant, when it was exposed, followed down the knife with his thumb and compressed it immediately above the point of section. It was then tied immediately. It was now found that only the lower part of the bone had been removed, and that the upper epiphysis still remained attached to the joint. It was then grasped with the lion-tooth forceps and dissected out. Seven arteries in all were tied, and the stump thoroughly washed with cold water. The edges were brought together with silver-wire sutures in the usual way.

After the operation the case proceeded much more favourably than his delicate appearance and low condition at the time of operation led one to expect.

Two ligatures came away on the 28th, three on the 30th, one on the 31st, and the last on the 5th of August. Up to the present date he is progressing most favourably.

A bed-sore on the sacrum has been a most unpleasant complication, but the use of Surgeon Porter's bed-sling prevented its becoming of any great size, and now that he is able to sit up it is healing admirably.

When the arm had been removed it was found that the abscess extended at least 4½ inches down the shaft of the bone, which was quite denuded of periosteum, and was, as stated above, separated from its upper epiphysis. The shoulder-joint was healthy. A considerable abscess had formed around, but did not involve the elbow-joint. The whole limb was œdematous, and suppurating sinuses existed in several parts both of the upper and lower arm.

The knee, which at one time gave some grounds for alarm, lest it should take on a similar action to that which manifested itself in the arm, is now much better, though not quite recovered. There is no sign of inflammation or swelling around it.

The subject of *post-mortem* examinations has again come forward. On this occasion the officers of the London Hospital declined to give a certificate of the cause of death of a patient who died soon after admission without making a *post-mortem*, which the friends refused to allow. A coroner's inquest was the result.

Literature.

THE STATE OF THE MEDICAL PROFESSION IN GREAT BRITAIN AND IRELAND.*

Pressure upon our overcrowded space has prevented us being able to refer earlier to Dr. Dale's Essay on "The State of the Medical Profession in Great Britain and Ireland." It will be in the remembrance of our readers that Dr. Dale was one of the unsuccessful competitors for the Carmichael Prize. The essay before us was written in competition for it, and, owing to a dispute respecting the award, was published without alterations. The nature of the subject presenting a valuable theme for the essayist, we do not wonder at several essays being written; but we are astonished at the manner or way with which the subject has been treated by the different authors. Our duty now is simply to confine ourselves to Dr. Dale's Essay, the opening chapter of which is an investigation into the curriculum of our licensing bodies. Dr. Dale quotes from the Medical Press respecting the rivalship in the different licensing bodies, the underselling and facility by which diplomas are given, &c. But very brief space is allowed to the all important and existing evil of our Profession—the constitution of the Medical Council. However, *representation of the whole Profession* in it is advocated, whilst the originality and paternity of the scheme is withheld after the manner of some of our jealous-minded contemporaries, whom we now perceive work week after week upon the subject-matter of medical representation first enunciated in these pages.

Part II. of Dr. Dale's Essay is devoted to *the general and moral training* of medical students, which is made up of a theological discourse equally applicable to the students of other professions. Part III. surveys *the state of the hospitals and schools of medicine, surgery, and pharmacy*, wherein the subjects of clinical instruction, lectures, *post-mortem* examinations, dissections, supply of subjects, and operations are considered with a very superficial pen to the neglect of more important detail. However, to none of Dr. Dale's remarks can we take direct exception, because they are mere recapitulations of well known facts, or established essentials which no serious-minded student entering upon his Second Session is unlearned in, or foolish enough to ignore. Part IV. enters upon, cursorily, *the state and mode of testing the qualifications of candidates of the different licensing Colleges or Corporations in medicine, surgery, and pharmacy*, a mere synopsis of the information to be obtained, and no doubt gathered, from the Calendars of the several corporate bodies. An appendix on Homœopathy concludes a pamphlet of seventy-six pages. We must candidly acknowledge after we have waded over every page of this unsuccessful prize essay—allowing that we have been unable to note a single original remark of value, or an observation that we could consider worthy of attention, or a suggestion which would convey the notion, or impress upon us, that Dr. Dale either devoted much time in preparing or writing, or reflecting over the subject matter of the essay before us—that there is much information contained in it in a compact form, gathered from various sources, which will, doubtless, be useful to any gentlemen contemplating joining the Medical Profession; but that it is an essay original in suggestions, or exhaustive of the present state of the Medical Profession in Great Britain and Ireland, we deny. In justice to Dr. Dale, we honestly allow, writing with an unbiassed and disinterested spirit, that after careful perusal of all the Carmichael Prize Essays, our astonishment has been aroused to the fact that more thought and more reflection were not devoted to the subject, and greater research practised by those writing upon so important a theme, with so extensive a field open before them; and our remark applies to the successful, as well as unsuccessful, Essayists. C. W.

* The State of the Medical Profession in Great Britain and Ireland. By William Dale, M.D. Lond., M.R.C.S., &c. Dublin: Fannin and Co. London: Longmans.

THE LAWS OF VITAL FORCE IN HEALTH AND DISEASE.*

The author of this little work says he has no ambition to assist in the formation of a new and exclusive medical sect. On the contrary, he conceives that the exercise of the right of private judgment is not more the privilege than the duty of everyone who undertakes the responsibilities of medical practice. The admittedly unsatisfactory state of therapeutics is his apology for endeavouring to apply the doctrine of conservation of force to practical therapeutics. He quotes from Sir T. Watson's late address to the Clinical Society—"Our Profession is continually fluctuating on a sea of doubts about questions of the gravest importance. This uncertainty is a standing reproach to the calling we profess. It has shaken the faith of many men, both able and thoughtful, and driven to ask themselves whether any kind of medication, other than the vis medicatrix natural, is of any real efficacy or value." The object of our author in his work, he says, "is to promote unity, defend liberty, and inculcate charity."

We may notice in this work a rather too great proclivity to lug in words such as "Creator," &c.; also "Mosaic account of Creation when God made the world." Now-a-days this is not considered good taste in scientific matters, in which causation has to be explained, and supernaturalism is not wanted. For instance, it immediately vitiates our idea of Dr. Haughton's philosophy when we hear in a work on vital force that his belief is, that there is but one kind of force in existence—the volition (will?) of God. He has no need to bring in the *Deus ex machinâ*, since he observes that the main idea he seeks to enunciate is that, in the building up of organisms, the ordinary physical forces are made use of, and that almost the whole of hygiene and therapeutics consists in a knowledge of how these forces operate on the body, and how remedies can be best applied in accordance with its natural constitution. Dr. Haughton says that perhaps the lowest organisms merely represent force in combination with inorganic matter; and the nobler ones complicated reservoirs of force in continuation with *highly organised* matter. For instance, "The power of generating nerve force, or that vital energy which the nervous system stores distributes, and conducts, exists in the human body as the result of the assimilation of organised food and the presence of a circulating fluid constantly renewed." He adds with great truth, "Although the metaphysician may shrink from considering the human body in the light of a machine, it is capable of the most complete demonstration that even the human will is not a generator of force." On this point Professor Bain's "Emotions and the Will" may be read with profit. According to Dr. Haughton, then, "All vital action depends upon power acting through an organism; and life is the condition which determines whether the external forces shall produce physical or vital changes. When this action is sufficient in amount, equably distributed, and regular in its periodic intervals of action and repose, the condition is a healthy life. When the amount of force is insufficient, the intervals become irregular; and *vice versâ*, when this irregularity is interfered with, the power of appropriating force diminishes. The result is diseased life. From this we see that disease is really a minor degree of life, and death is the total absence of life. The whole art of curing disease, then, consists in increasing the working power of the human machine, and preserving the equability and regularity of its action." He goes on to say that, "Nothing can be more certain than that none of the medical systems that the world has ever witnessed are based on any such foundation. The above principle allows of the use of every remedy; and, according to it, the action of a therapeutic remedy may sometimes be antipathic, sometimes counter-irritant, and sometimes re-active, or homœopathic; whilst it fully acknowledges the depurative properties of the vapour bath, and the therapeutic efficacy of the water cure. It does not, however, accord with the employment of infinitesimal doses of medicine, inasmuch as, were the human organism sufficiently sensitive to be acted on by them, it would be in hourly danger from morbific agents which float in the atmosphere in far more appreciable quantities." Most of this is very much to our taste, and we therefore can recommend the perusal of this little work. D. C.

* The Laws of Vital Force in Health and Disease. By E. Haughton, A.B., M.D., &c. 2nd edition. Churchill, 1869. Pp. 88.

SPECIAL CORRESPONDENCE.

DR. CHARCOT'S CLINIQUE.

[FROM OUR OWN CORRESPONDENT.]

Paris, July 28.

Some time ago M. Charcot made some interesting observations on the question of the "Lesions of Nutrition" which ensue upon diseases of the nervous system. "One of the first points," observed M. Charcot in a lecture at the Hospice de la Salpétrière, "to be considered regards that which takes place when the sciatic nerve is cut." Schroeder Van der Kolk, who was the first to make this experiment, attributed the disturbance of nutrition which ensued rapidly in such cases in the corresponding limb, to the absence of the nervous action; but Brown-Séquard repeated this experiment in 1849, and showed that this disturbance of the nutrition only takes place because the animal is unable to remove from the influence of external influences the limb which has been deprived of sensibility by cutting the nerve. When the animal which is operated on was surrounded with all necessary precautions, they no longer perceived any modification of the nutrition in the paralysed limb. Section of the trifacial nerve gives analogous results. The alteration observed subsequently to this in the eye, which at first was considered as the effect of a perversion of the nutrition resulting from division of the nerve, has been, since the experiments of H. Snellen, placed to the account of the anæsthesia which exposes the animal to shocks of all kinds. Again, the destruction even of a large part of the spinal cord, is not followed by immediate disturbance in the nutrition of the paralysed limbs. Thus the posterior limbs of a kitten, which survived three months after vivisection, developed themselves normally, and the electric sensibility of the muscles remained intact. If, in like circumstances, eschars ensue, this is because the animal remains soiled by urine.

According to these facts, experimental physiology shows that the absence of the nervous system does not bring to the anatomical elements any other disorder of nutrition than what are developed in these same elements under the influence of prolonged inactivity.

The discovery of the vaso-motor nerves and of the effects which cause the palsy of those nerves ought not to modify this formula essentially. In the first place, in healthy animals, the hyperæmia which they produce is not sufficient, in general, to occasion by itself an alteration of the nutrition of the tissues. Again, in diseased animals, there may occur spontaneously, or after the slightest excitement, some modifications of nutrition to be compared to those found in man, in cases of disease of the nerve centres. The same thing, however, does not hold good with regard to the lesions which take place when there is an irritation or inflammation of the nerves. According to the experiments of Snellen, anæsthesia of the fifth pair of nerves is considered necessary for the production of opacity of the cornea; but in man, in some affections of the fifth pair, accompanied with hyperæsthesia, we see arise in the eye disturbances of the nutrition, because in this case there is irritation of the nerves—an irritative inflammation of the nerves. Such are, in particular, the observations of Bock, of Friederich, in which the nerves were compressed and irritated by tumours; Samuel, by irritating the fifth pair of nerves within the cranium, produced very rapidly derangement of nutrition in the eye. This experimenter

placed two needles on the Gasserian ganglion and passed a current of electricity through them. He saw the vessels of the eye become rapidly injected; at the end of twenty-four hours the injection was replaced by a sharp inflammation which lasted two or three days. In these conditions there was not anæsthesia, but hyperæsthesia, in the parts supplied by the fifth nerve.

Here again are some experiments relative to the fifth pair. Meissner and Schiff saw alteration of the nutrition arise in an eye, without anæsthesia occurring along with it, after incomplete division of the trifacial in the cranium. Are not such incomplete sections of nerves favourable to inflammations of the nerves? We know that among experimenters some say that they are certain to obtain grave lesions in the nutrition of the kidneys on destroying the nerves supplying these organs, whilst others, when they have repeated this experiment, have had only negative results. Benedict has observed in man a fact we may cite here:—Having excited with a galvanic current the great sympathetic in the neck, he saw arise under the influence all the symptoms of a sub-acute arthritis in the joints of the corresponding upper extremity. If the lesions attack the spinal cord, what do we see? The experiments of M. Brown-Séquard teach us what they do. When a part of the spinal cord is divided or destroyed without any inflammation of the parts, we find only, besides the paraplegia, effects caused by the reaction of the parts. What a difference between this and cases where there is myelitis produced experimentally! Then the muscular atrophy is very rapid, and eschars appear rapidly in spite of the greatest care. In what way, by what mechanism, does this irritation of the nerve centres come to influence peripheric parts, and produce in them the lesions of nutrition, of which we have given examples? Are the latter due to irritation, or paralysis of the vaso-motor nerves? Or do they, again, depend on an irritation of the hypothetic nerves, which anatomy does not as yet recognise, and which are sometimes spoken of under the name of trophic nerves.

Among the traumatic lesions of the nerves there is a fundamental distinction to be made: sometimes the lesions consist in a clear and complete section, and then the effects are simply, at least in general, those of absence of nervous action; sometimes resulting from wounds or contusions, they are of irritative nature, and in this case we see arise those derangements of nutrition to which I call your attention. The traumatic lesions of the nerves may give rise to phenomena of a morbid character affecting the skin, the sub-cutaneous cellular tissue, muscles, and articulations, and bones. The late American war has been, you know, the occasion of very important studies upon this subject. These have been presented by W. Mitchell, G. R. Morehouse, and W. Keen, in a very interesting work. With regard to the skin, the accidents which the traumatic lesions of the nerves are apt to occasion in the integuments are of two kinds. The first consist in eruptions of a variable kind, but especially vesicular or bullous. We shall cite in the first place zona, which is observed frequently in like cases, and which on this account might be named traumatic zona. Under the name of eczematous eruptions, the American surgeons, too, have described an affection of the skin which it appears to me might be attached to the preceding variety.

In the second place we have pemphigoid eruptions. I saw a case where bullæ and pemphigus developed themselves very rapidly on different parts of the integument, corresponding to the wounded nerve, and left behind them indelible marks. In the third place we may cite a redness of the skin which reminds us of *erythemapernio*, and a certain tumefaction of the skin and subcutaneous cellular tissue which simulates phlegmon. Then comes the affection called *glossy skin*. The skin is glossy, pale, anæmic; the sudoriparous glands are atrophied, and their secretion diminished; the epidermis is cleft, and the nails split and curved in a curious way.

The muscles often become rapidly atrophied, and lose in part, sometimes wholly, their electric contractility. The joints, when there are traumatic lesions of the nerves, have symptoms which remind us in a remarkable manner of the physiognomy of acute articular rheumatism. These affections of the joints very speedily bring on anchylosis. Periostitis often followed by necrosis may occur. The American authors we have spoken of say, that these connective affections are almost always preceded by a burning pain, in proportion to the state of irritation of the wounded nerve. They make the remark that there are developed habitually, often continuous, pricks, or incomplete sections of the nerves, that is, after these traumatic causes most likely to produce inflammation of the nerves, or at least a condition of neuralgia. On the other hand we don't find them in cases of complete section of the nerves.

Disturbances of nutrition are also observed in cases where the nerve lesions are spontaneous. In cancer of the vertebral column, which brings on softening of the vertebræ, a destruction of the vertebral laminæ, and, consequently, a constriction in the conjoined foramina, may compress the nerves and sometimes inflame them. In such a case I have seen an eruption of zona occupy all the regions where the branches of the cervical plexus are distributed to, in consequence of the compression which the nervous trunks underwent in the foramina. And in certain cases of meningitis of the spinal cord, with hypertrophy of the dura mater, the irritation of the nerves in their passage through the membranes may be followed by accidents of the same kind.

It is, however, above all, in anæsthetic leprosy that we find, in all their development, the lesions of nutrition which we have studied *àpropos* of the traumatic lesions of the nerves. The initial morbid process consists, as Virchow has so well pointed out, in a leprous perinervitis, characterised by a special cellular proliferation in the middle of the nerve tubes which it slowly destroys. The nerves then frequently present in their course a fusiform swelling, which sometimes may easily be recognised during life in the regions where it is superficial, as the elbow when the ulnar nerve is affected. These alterations produce at the beginning symptoms of hyperæsthesia, and later of anæsthesia.

SIMPSON.

The *Family Friend* in its August number, being the 8th number of a New Series, contains a portrait and brief life of the late Sir J. Y. Simpson. In the biographical notice, we find three anecdotes said to have been supplied by a lady, who knew the deceased baronet intimately, and which we extract.

"I have sent to old Mr. T. to make sure of *correctness*. Professor Simpson worked with his father, a baker, at Bathgate. It was through his brother's kindness, and a bursary—(a bursary is a grant of a certain sum for a year or number of years to young students, who have given proof of their abilities, to maintain them and aid them in prosecuting their studies while at college)—that he was enabled to attend the University of Edinburgh. I have no way of ascertaining whether he was regularly apprenticed to his father or not; but undoubtedly he was intended for his father's trade.

"Whilst residing with his brother at Stockbridge, Mrs. T.—(since dead, wife of old Mr. T.)—was seized with cramp of a violent nature during the night, and, knowing of the medical student that lived near, sent for him. From that time till he became a great man they were on intimate terms. He confided his sorrows to her, and asked her advice on various points. Amongst other points she told him that in his particular department he need not expect to get much practice as an unmarried man. He thought he could soon qualify himself in that respect, as there were several daughters in a *genteel* family, either in Dean terrace, or one of the streets leading off it—(then, and still, a genteel neighbourhood)—I forget which, any of whom would accept him, he supposed, as all had been so kind to him, and made him welcome as a guest at all times. He went—proposed—and, was dismissed the house for over on account of his presumption; but he took the

repulse so coolly, that Mrs. T. did not credit him with warm affection.—(He displayed the warmest affection to the lady he afterwards married, and that affection was reciprocated.)

"When he was a candidate for the chair in the medical department, which he made specially his study, Mr. T. and Mr. Young, both butchers in Stockbridge market, went to all the members of the Town Council, in whom, along with the patrons, lay the appointment of a professor for the vacant chair, soliciting their votes in his favour. Simpson was named after Mr. Young's father—James Young. The late Mrs. R. told me she took him to each of the patrons and introduced him, after having begged their votes in his favour; and on their way to one of them—a consequential body—she advised him to be as much as possible on his P's and Q's, as the gentleman expected great deference from all asking favours. To her horror, when the patron asked what his occupation had been to fit him for the position he aspired to, he answered, 'Eight years previously he had been chiefly employed in driving a bread-cart; since then his testimonials would show how he had been employed.'"

WEDNESDAY, AUGUST 3, 1870.

ARMY MEDICAL REPORT.

II.—THE BRITISH ARMY ABROAD.

IN our last notice of this valuable Blue Book we spoke of the health of the troops within the precincts of the British Islands. We now proceed to examine the condition of those inhabiting the dependencies of this great Empire. At Gibraltar in 1868 there were habitually about 4,631 troops, and they seem to have been very healthy, as only 8·43 per 1,000 deaths took place; about 224 per 1,000 admission for venereal disease occurred. In Malta the average strength of troops in 1868 was 5,377, and the mortality was very high, as much as 18·97 per 1,000. Malta is very free from venereal disease among soldiers—only 70 admissions per 1,000 took place in 1868. Sir H. Storks, we believe, was the cause of this immunity in the Maltese Army. Continued fevers raged in 1868, and were the cause of the great mortality. In Canada, the average strength of troops in 1868 was 9,582. The deaths were 10·33 per 1,000—not far, it will be noticed, from the average at home. Enthetic or venereal disease occasioned 192·6 admissions into hospital per 1,000; but not a single death. In Nova Scotia there were about 3,519 troops in 1868, and the mortality 9·65 per 1,000. Venereal diseases unfrequent—only 122·5 admissions per 1,000 into hospital, and no deaths. Foggy Newfoundland had 300 troops stationed in it, and Bermuda, with an average of 1,649 troops, had a very high death rate, 24·86 per 1,000, chiefly from continued fever. In the West Indies, again, in what is called the Windward and Leeward command, there were 806 white troops in 1868, who were very healthy, only about 9·92 deaths per 1,000 having occurred. Venereal diseases were very prevalent; no less than 342·4 cases per 1,000 having been admitted into hospital in 1868. In Jamaica, the white troops in 1867 were 778 in number, and they were exceedingly healthy, only 7·70 deaths per 1,000 having occurred. Venereal diseases were very unfrequent, only 108·0 per 1,000, with no deaths. We believe that the soldiers in Jamaica live maritally with the native women, and hence the rarity of contagious disease. The black troops were by no means so healthy. No less than 19·37 per 1,000 died out of 878 men, and it appears chiefly of tubercular diseases, which destroyed no less than 10·25 per 1,000 of them. Venereal diseases were rife among them, and no less than 375·9 admissions on this account occurred among them. The Bahamas are kept almost solely by black troops, of whom there were 337, and the mortality among them was on the ratio of 14·64 per 1,000. Venereal diseases prevailed—no less than 599 per 1,000 troops were admitted into hospital on this account. Tubercular diseases carried off no less than 11·87 per 1,000 of the black troops. This is the more remarkable because at Honduras, out of 270 black troops, with the same mortality, 14·11 per 1,000, not a single death is said to have occured from tuberculosis, miasmatic diseases prevailing, and accidents and suicide being common.

In Western Africa there are only 15 white troops, but about 924 black men, among whom the mortality was very high, 22·12 per 1,000 in 1868. The highest mortality, 31·96, was at Sierra Leone; the next, 30·11, at Gambia; and the lowest, 25·00, at Lagos. Enthetic diseases were not very prevalent; only 296·8 at Sierra Leone were admitted per 1,000 from these diseases, and there were hardly any deaths. It seems almost incredible that no less than 15·98 per 1,000 poor black troops died of tuberculosis at Sierra Leone in 1868. We suspect that the barracks are exceedingly crowded, and that no care is given to ensure sufficiency of cubic space; but this is not spoken of in the report. Black troops are probably not sufficiently important to our rulers.

St. Helena has always been a healthy station. In 1868, 421 troops were quartered there, and only 4·75 per 1,000 died. It ought to be used as a sanitarium for invalids and consumptives. Enthetic disease prevailed, and there were 337·3 admissions per 1,000 in 1868 from this cause, although it is stated that the "Prevention of Diseases Acts is in force." The increase has been nearly alike in syphilis and gonorrhœa.

We now come to the Cape of Good Hope, at which about 3,630 troops dwelt in 1868, with a death rate of 12·11 per 1,000. Venereal diseases were very frequent in the Cape, as many as 368·6 admissions per 1,000 having occurred from this cause. Tuberculosis killed 3·03 per 1,000. In the island of Mauritius in 1868 there were about 1,318 troops, with the high mortality of 27·41 per 1,000. Mias-

mata caused a great slaughter in that dangerous island, namely, of 16·69 per 1,000. Enthetic disease is very little spread among the troops, as only 90 per 1,000 were admitted into hospital from this cause in 1868. "Port Louis will always be an unhealthy station."

We come now to the island of Ceylon, where the average number of the troops in 1868 was 923, and the mortality 21·89 per 1,000. There was not much enthetic disease in that year, only 154·3 per 1,000 admissions having taken place; but no less than 12·15 per 1,000 were killed by miasmata, dysentery, and diarrhœa. The black troops, of whom there were 1,028, had about an equal mortality, 21·40 per 1,000. They were almost free from venereal disease. Why? We wish the report had given us a reason why only 26·3 per 1,000 were admitted for venereal disease in 1868. Are the troops married?

In Australia and Tasmania there were 1,690 troops in 1868, with a death rate of 13·02 per 1,000; of these 3·55 per 1,000 died from tuberculosis, showing that Australia is by no means free from this disease; 238·5 admissions per 1,000 occurred from venereal disease. In New Zealand there were 841 troops who were very healthy, 8·32 per 1,000 having died in 1868. Here again, venereal diseases are uncommon, only 65·4 per 1,000 having been admitted for this cause; and it is added that this was greatly above the average. Why is this? Are the soldiers married?

Turning to China, we find 668 white troops there in 1868, with a mortality of 14·97 per 1,000. There was not much venereal disease, only 182·6 per 1,000; but tubercular disease carried off 4·48 per 1,000. There were 691 Asiatic troops, with the high mortality of 24·60 per 1,000, chiefly from miasmatic disease and disease of the lungs. Venereal disease is very unfrequent among these troops; only 42·2 per 1,000 were admitted in 1868. "The low ratio of these cases is attributed by the medical officers to the manner in which the Prevention of Contagious Diseases Ordinance, passed in 1867, has been carried into operation. A reference, however, to the prevalence of these diseases among European troops shows that no such benefit was derived by them, and even among the Asiatic troops the Gun Lancers had 15 cases on an average of 71 men. In Japan there were about 785 troops in 1868, with an average death rate of 14·01 per 1,000. It is curious to observe how high the amount of venereal disease is in Japan, no less than 554·1 per 1,000 admissions per 1,000 having occurred during the year 1868, with no death from this cause. There is a note in the report to the effect that "enthetic diseases were nearly one-third under the proportion of 1867, though still a little above the average, the admission amounting to more than half the strength. The reduction is attributed by the medical officer in charge to the intervention of the native authorities at the suggestion of our Minister. The reduction has taken place almost entirely in the syphilitic group of these diseases." Singapore and Penang had about 183 troops in 1868, with a high mortality of 21·84 per 1,000. Venereal disease prevailed among them, 377 per 1,000 having been admitted into hospital; but no deaths occurred. Nearly half of the deaths, however, were from accidents, so that the troops were really very healthy. The daily rations for the soldiers there is mentioned as being 1¼ lb. bread, 1¼ lb. beef, 14 ozs. fresh vegetables, 2 ozs. rice, 5-7th oz. tea, or 1¾ oz. coffee, 2½ ozs. sugar, 1 oz. salt, and one ration of fuel—*i.e.*, 3 lbs. wood to each man.

We come now to the great empire of India, where in 1868 there were about 52,887 troops, with a death rate of about 21·70 per 1,000. Bengal had a death rate of 22·93; Madras, of 23·92; and Bombay, of 15·48. In Bengal there were 32,909 troops in 1868. The chief disease was miasmatic, and this killed 7·29 per 1,000; then dietic disease killed 3·96 per 1,000, tuberculosis killed 2·40 per 1,000; enthetic diseases caused 188 per 1,000 admissions into hospital in 1868. Spasmodic cholera did not prevail as an epidemic during the year at any of the stations, except Chinsurah and Jubbulpore. "Enthetic diseases were more prevalent than in 1867 in all the Military Divisions, except the Meerut Division, in which there was a considerable decrease; and the Serhurd, in which the results for the two years were identical. So far, therefore, as the prevalence of these diseases in the Army may be taken as an index, the establishment of Lock Hospitals does not seem, as yet, to have produced satisfactory results. The regiments in which primary syphilis caused the greatest number of admissions were the Second Battalion 25th, in the Presidency and Rohilcund Division, the 36th in the Peshawur, the 107th in the Allahabad, and the 105th in the Meerut Division. The latter corps had the largest number of cases of secondary syphilis." There were 84 cases of sunstroke or heat apoplexy fatal. In Madras, with 10,158 troops, 5·41 per 1,000 died of miasmatic diseases, 2·56 per 1,000 of diseases of the nerves, and 7·19 per 1,000 of diseases of the digestive organs. There were 258·5 per 1,000 admissions into hospital for venereal diseases, and three men died of these diseases in 1868. Inflammation of the liver prevailed, and heat apoplexy. There was no epidemic of spasmodic cholera, and only 7 deaths occurred from it in the whole command. In Bombay there were 9,820 men in 1868, of whom 3·97 per 1,000 perished from miasmatic, 2·14 per 1,000 from tuberculous, and 3·25 from diseases of the digestive organs. There were 197·6 per 1,000 admissions into hospital for venereal diseases. More than half of the accidents were from sunstroke or heat apoplexy. Spasmodic cholera did not prevail at any of the stations in 1868. There were 8 deaths from it at Poona. Enthetic diseases were more prevalent than in 1867 in the Mhow, Northern, and Aden Divisions. During the year an Act came into operation under which supervision of prostitutes and the establishment of Lock Hospitals at the principal stations was authorised; but it has not been in operation for a sufficient period to have yet produced any material effect on the prevalence of this class of diseases. One curious fact is, that at Aden there were only 86 per 1,000 admissions for venereal disease in 1868. How is this to be accounted for? Were the men married? During 1868, 2,382 invalids were sent home from India, or 45·04 per 1,000, of these 1,097 were discharged at Netley. Rheumatism caused the discharge of 57, venereal disease 958, tuberculosis of 141, disease of the nerves 113, and of the heart 211; disease of the digestive organs caused the discharge of 147, and disease of nutrition of 180. There were 52·96 per 1,000 troops daily sick in Bengal. In Abyssinia in 1868 it seems that ten deaths occurred from sunstroke. There was no death from war casualties. The men daily sick were only 17·11 per 1,000. The mortality in 1868 was considerable on board ships returning from India *viâ* Egypt; three deaths occurring from dysentery, two from hepatic disease, &c.

The admissions into hospital were rather high among the troops returning by the Cape, chiefly from the occurrence

of venereal disease among the men from Yokohama, Japan, where the diseases were very prevalent.

There is an interesting table at the end of the report showing the sickness, mortality, &c., comparatively. We there find that white troops in the United Kingdom have an annual death rate of 9·34 per 1,000, and 49·20 per 1,000 are constantly non-effective from sickness. In Ceylon, again, the death rate being 23·20 per 1,000, the constant sickness is 69·60 per 1,000 ; and in China and Japan, with a death rate of 54·94 per 1,000 from 1860-67, there was constantly sick no less than 77·11 per 1,000. In India, with an average death rate of 27·64 per 1,000, there were an average sick list of 63·86 per 1,000. Such facts prove but too strongly that the notion of our section of the human race colonising the whole of the habitable globe is irrational and anti-hygienic in the extreme, and that it would be infinitely more rational on our part to withdraw gradually from all tropical climates, except in so far as they are proved to be compatible with the longevity and health of our troops.

THE DEFEAT OF THE MEDICAL BILL.

Last week we were able to congratulate our readers on the defeat of the Bill which the Privy Council were so anxious to force on the Profession. It is not worth while, now the danger is happily over for a time, to repeat our criticisms of its details. Still, as next year the question of Medical Reform must come on again, we think it well to state that no Bill, destitute, as this was, of all consideration for the wishes of the Profession, has any chance of passing. We ask two things—1st. A single State examination for a licence to practise. 2nd. Representation in the Council supported by our money. These two things are as much for the good of the public as the Profession, and but for the obstinacy of Lord de Grey might have been attained. Let it never be forgotten that in the House of Peers, when pressed on the subject of representation, Lord de Grey spoke decisively against any such measure of justice, and otherwise evinced a disposition to treat with indifference, if not with insult, the wishes of the Profession. We predicted, at the time, that his Bill would never pass the Commons, and the Government has been compelled to withdraw it. Now that the Profession is roused to a sense of what is its due, we hope it will not sink again into its wonted apathy, for a further attempt on its dignity is certain to be prepared in the recess. We have, however, good reason to hope that no future Bill will be manipulated through the Lords, as this was, without representation being granted. Besides, medical reformers are now awake. They see how far the Privy Council dare go, and being thus forewarned will be forearmed. Measures will be introduced into the House of Commons, that will at least be likely to influence the course of legislation. Dr. Brady, for instance, has given notice of a Bill, and so also has Dr. Brewer. The former will probably be the spokesman of the Royal College of Surgeons in Ireland, a body that has evinced its zeal and sincerity by keeping Dr. Hargraves and Dr. Macnamara in London to combat the pernicious provisions of the Bill, and by the really self-sacrificing tone of its just demands. Dr. Brewer's success in other measures points him out as a most suitable member to take up the question. Indeed, as already is known to our readers, he had a Bill prepared which he was ready to introduce this year, but joined the other medical members to secure the rejection of that of the Privy Council. His Bill provided for representation of the Profession in the General Council, and it was because the Government refused to grant that one demand that all parties combined to reject their measure. We may, therefore, with confidence, look forward to the future, feeling that perseverance will end in speedy success.

Notes on Current Topics.

A New Thing in Journalism.

The *Pharmaceutical Journal*, as our readers know, is now a weekly. It has obtained a new editor, and the person selected by the Council of the Society for that office has certainly signalised his accession to the editorship by an unprecedented act. We were never more surprised than when we took up a recent number which did not fall into our hands till rather late. Then we observed that a series of notes were appended to one of the Original Communications. It seems that the late editor, aware, no doubt, of its extreme value, had commenced the publication of Dr. Letheby's paper on the "Prospects of the Sewage Question," which has already appeared in our columns. Considering the great interest of the question just now, we are glad to see such a paper so extensively circulated, and were not surprised at the late editor finding it a place in the columns of the *Pharmaceutical Journal*. But it was not completed in his term of office, and so the latter part of it had to be issued under the new editor's auspices. But it appears the new editor does not agree with Dr. Letheby, and so takes the opportunity of adding foot-notes to his paper, controverting his conclusions. A finer specimen of impudence we never remember, and it augurs ill for the tone the journal seems likely to take under its new management. But this is not all : the notes, being unsigned, would give the idea that they were the author's, and so he might at first sight appear to contradict himself, while many would not read a paper so overladen with foot notes, as if the writer could not or would not write clearly. In fact, we should ourselves have passed over this paper altogether, having already carefully digested it when it appeared in the Medical Press, but were struck by the number of notes of which we had no recollection, and began to read them to see whether Dr. Letheby had added them since our publication, and whether he had therein modified his opinions. We soon discovered the trick, and, as soon as we partially recovered our surprise at this editorial novelty, began to ask why in each case the words *Ed. Pharm. Journ.* had not been added to the notes. Could it be that the editor would not allow them as he did not really write them ? Judging from internal evidence we should say decidedly they are not his own production. But surely it would have been more in consonance with editorial usage to permit the person who wished to controvert Dr. Letheby, to write a paper in his own name, than to drag the organ of the Pharmaceutical Society into a controversy so acrimonious as that on sewage is becoming, and rashly to commit such a periodical to one side of a difficult chemical question that lies outside the bounds of pharmacy ; and, above all, to rush headlong into this obstrusive discussion, against such a leviathan of debate as Dr. Letheby. It would really appear that the sewage question, while it grows more

and more important has been overlaid with so much personal or interested writing, so much determination to bear down all differences of opinion by any and every means, that men are being led by foregone conclusions to lengths that independent journals may well protest against. We shall have more to say on the general question in a future issue. Meanwhile we cannot refrain from saying that the Pharmaceutical Society ought not to be made a means of disseminating such notes as these we again protest against.

Our Sick Poor.—A Warning.

It has been our experience that no profession is so unfairly tampered with by amateur experimentalists as that of medicine. But what surprises us most is the fact that men educated in other respects, and apparently possessing good sense, should be so foolish and indiscreet as to tamper with drugs, whose therapeutical effect and applicability of exhibition they are entirely ignorant of. In country districts we find the priest, or parson, as the case may be, advising and prescribing with a recklessness which a little consideration on their part should deter them from doing; and in some instances where a medical man is in actual attendance, not only advising the taking of certain drugs, but actually providing them. This is in nearly every instance done *sub rosa*—the medical attendant being ignorant of their interference. Doubtless, the sick poor, who pander to the parson for the sake of his shilling, or old coat, encourage the practice by expressing their thankfulness for the relief the parson's dose has bestowed. But an educated man should know better than plunge into using medicines whose effect he cannot foresee, and remember that "a little knowledge is a dangerous thing," and that he has no more right to trespass upon the domain of the doctor, than the doctor has to get into his pulpit and preach to his congregation.

These remarks are forced upon us owing to an occurrence which happened to a medical gentlemen, whose name is familiar to the readers of our pages, at the commencement of the present week. He was summoned to visit a patient whom he found suffering from acute nephritis. The man had been mowing grass, became heated, drank freely of beer, and in the evening exposed himself to cold. The usual remedies were resorted to by our contributor, and the more pressing symptoms were yielding to a scientific treatment, when the parson who came to the rescue, not satisfied with confining himself to the salvation of souls, and finding the man did not pass water, thought he would compel him at least to secrete it, so he compounded several doses of acetate of potass, spirits of nitre, and decoction of broom, which, he had the presumption afterwards to tell the doctor, when an explanation was demanded, "was the finest thing in the world for the water." The patient died, of course, from uræmic poisoning. It is not likely that this individual conscience-stricken pastor will trifle again with human beings' lives, but we record the case and make the comments we do that others may take warning; for although there is no law to punish such erroneous behaviour, there is "a still small voice within" to remind the wrong doer. Well may the sick poor in the time of suffering ask to be saved from their friends, and well may the doctor pray for the dawning of the day when wiser legislators will protect him in his all important duty to ward off disease and relieve human suffering, by a code of law which will have for its object the punishment of amateur experimentalists with drugs and all those who trifle with human beings' lives.

A Humane Board of Guardians.

The following letter has been sent to us by a correspondent :—

"Sir,—I am desired by the Board to call your attention to the following memorandum inserted in my application book by the chairman of the relief committee at the last meeting of the board—

"'The guardians are surprised at the order being given for brandy and meat for a man in dying circumstances.'

"I am, sir, yours truly,

"G. A., Relieving Officer.

"July 23rd, 1870."

The idea of ordering brandy and meat to make beef-tea for a dying man!!! Our correspondent tells us the deceased was dying of phthisis, accompanied by diarrhœa; that each week he received three pounds of meat from the parish; the day of his decease was the time to order the week's allowance, and finding him suffer from diarrhœa, and in a deplorable state, with a family in abject poverty, the humane doctor ordered in addition half-a-pint of brandy, with we see how humiliating a result. We pity the parish doctor who is subservient to the petty huckster or small farmer, but our humanity carries us further, to the bed of the dying pauper; and we ask what philanthropy means, and if paupers seriously ill are to be allowed to die for the want of necessaries because of the inhumanity and ignorance of Poor-law guardians?

Tight Boots and Weak Eyes.

There is something after all in the notion and belief of our old lady friends that tight boots produce weak eyes. Since the new-fashioned boot made for and worn by ladies has come into use, we have been consulted in various instance for a weakness of vision, and a stiffness about the ocular apparatus, which we found at first difficulty in accounting for, since we were unable to detect any abnormal condition of the eye to cause this disordered vision, or to trace any constitutional disturbance likely to provoke functional phenomena. A mother, wise in her generation, given to bestowing roses to Harpocrates, the god of silence, asked us if the tight boots worn by her daughter might not produce the distressing symptoms of *asthenopia* complained of. To this we assented, and, upon the tight boots being dispensed with, discovered that the cause of the mischief must have been removed, for the injurious effect upon the eyes ceased—*sublata causa, tollitur effectus.* However disposed our fashionable ladies may be to wear the high built, conical-shaped heeled boot of the period, with narrow toes and light top soles, which throws the foot so prominently forward, and tends to compress it in a space which the boot-closer narrowly limits, and however anxious they may be to imitate the Lady Hester Stanhope, whose foot, it is stated, betrayed a royal race, for water flowed beneath the instep,—this we tell them in the hour of splendour and fashion, that the localised pain suffered from compression of the foot, and the consequent production of corns and bunions and distorted toes, so patiently endured in the self-sacrifice to outward, show are nothing compared to other symptoms which undue and

persistent pressure provokes, and which may be readily recognised in the unsteady bashful look about the eyes, the perpetually winking of the lids, and the contracted brow, so pathognomic of approaching weakness of sight—the asthenopia of the oculist—whilst we must remind them Propertius has written *oculi sunt in amore duces*, and we now teach them that at the expense of a neat foot they must not injure their eyesight.

The Bone-setter.

Few districts can boast being without a bone-setter, and some of them obtain a very wide notoriety for a reputed skill in discovering a dislocation, or an alleged tact in bringing to light what was hidden to the qualified surgeon's professional eye, or what his educated fingers failed to detect. The bone-setter is generally one of the lower class who follows some humble employment between the hours devoted to attendance upon patients. We regret to find in a few instances there are men possessing the College of Surgeons' diploma who specially practise this department, and are sure to work out the existence of a dislocation which does not exist. In the neighbourhood of Rochdale, there is one such. A correspondent tells us of a patient who went to bed apparently in good health, and awoke in the morning with a paralysed arm. For some weeks he remained under our correspondent's treatment and steadily improved in health and progressed towards recovering the use of his arm, when he was induced to consult this qualified bone-setter, who cast at once serious reflection upon the gentleman in attendance for overlooking an existing fracture, which he induced his patient to believe was done by injury during sleep. The hand and arm was at once placed in splints, neatly bandaged, and at the end of three weeks taken down, and "oils" provided for rubbing in to perfect the case. Of course this description of bone-setter, however ignorant he may be—for they are, as a rule, men who have failed in the Profession—never prove so dangerous to society as the common charlatan. He it is who does the irreparable injury. The history of the following case conveys all that we could well write on the subject. Last Christmas the son of a well-known clergyman at a public school, was thrown down by other boys and his knee injured. Placed at once in the infirmary under surgical treatment for synovitis, the boy rallied, and was able again to resume his school duties and join in the games. Unfortunately, again the knee was injured, when his parents removed him from the school and consulted their own medical attendant. Being of a scrofulous habit the case became complicated, and the mischief spread to the heads of the bone forming the articulation. However, under suitable treatment, the boy steadily progressed and was able again to walk upon the limb, when some way or other his father was induced to show the joint to a parishioner who practised the art of bone-setting. This party at once made out a dislocation—and the usual practice followed by them—there and then, in the presence of an educated clergyman, commenced pulling and twisting the joint about. Of course he sent home father and son in high glee—the dislocation was reduced and the joint cured! The doctors were maligned and abused by all for their ignorance, and the only regret was that the bone-setter was not consulted earlier! The result may be readily guessed; in a few hours violent inflammation succeeded all this pulling about; in six days there was no doubt about suppuration of the joint, and in three weeks amputation was necessary to save the boy's life. These things only happen too often, and the question follows how are we to remedy so great a grievance, and how are we to protect ourselves against the ignorant bone-setter?

The "Echo."

We correct the terms with which our respected and much-admired contemporary—the *Echo*—takes us to task for our note on mushrooms. We regret to find the editor objects to our using technical language, while he displays deplorable ignorance of the subject he touches upon. In the first place we do not write for children, and in the next he will find science *is* taught in national schools. We pity him for living in ignorance of this fact; few national school scholars who have learned the rudiments of botany but could understand all we wrote on the subject of mushrooms. Is there no such scholar on the staff of the *Echo*?

Panary Fermentation.

In some of our provincial hospitals and infirmaries wherein they bake their own bread, we have recently heard complaints made of the quality of it during the warm weather, and, when inquiry was made respecting the description of the flour used, nothing could be discovered to account for the bitterness complained about by consumers. In one or two instances we have been able to show that the disagreeable flavour was owing to the tedious process of fermentation practised by some, in others to the *yeast* used being unfit for baking purposes, and in a few rare instances to the baker adding sugar to the dough, whereby a too strong fermentation was produced. Setting aside the subject of baking powders, in which we have no confidence, and which are, in our opinion, inapplicable for baking bread for large institutions, we recommend German yeast to be used, after water at a temperature of blood-heat is mixed with the flour (and some salt added) to form the dough. After thus *setting the sponge*, and the process of fermentation manifested, and the confined gas escaped, we must take care that further fermentation does not take place, particularly during weather such as the present, or the bread will be spoiled. Kneading should be commenced and the dough perfected by the further addition of the remaining flour, salt, and water. We find much bread spoiled and rendered disagreeably bitter by the injudicious use of sugar. We believe the quantity of saccharine matter contained in flour ample, and any further addition of sugar not only superfluous but injurious to the quality of the bread.

Baboo Gopaul Chunder Roy.

This learned Indian gentleman will lecture at the Hunterian Society's Room in the London Institution, Finsbury Circus, this evening (Wednesday), at eight o'clock. Subject: "The History of Medicine in India." Members of the Profession admitted, with their friends, on presenting a card.

The Indian religious reformer, Baboo Keshub Chunder Sen, is a cousin of the lecturer, and is expected to address the meeting also.

British Medical Association.

The annual meeting is to be held at Newcastle-on-Tyne on the 9th, 10th, 11th, and 12th—Tuesday to Friday next. A room in the new Town Hall is set apart as a reception room, where members should apply as soon as they arrive. Arrangements for postage, telegraphic communication, information about lodgings, tickets, and other things all centre here. Dr. Phillipson, hon. local sec., will be glad to receive in advance names of members intending to be present. Some interesting practical papers are announced. Dr. Chadwick will resign his presidency on Tuesday, when Dr. Charlton, who succeeds, will deliver his inaugural address, and much general business will be transacted. Dr. Sibson, F.R.S., will deliver the address in Medicine on Wednesday, the 11th, at noon. The address in Surgery by Dr. Heath will be at 11 a.m. on Thursday. In the evening is the public dinner at the Town Hall.

On Friday, the 12th, at 2 p.m., there is to be a special convocation of the University of Durham to confer honorary degrees.

The New Insect Plague.

It has been announced by some of our contemporaries that mosquitoes have appeared in Woolwich. Some cases have come under our notice in the aristocratic neighbourhoods of Belgravia and Kensington, where these insects have been very annoying. Last year ladybirds came in thousands, we know not whence, nor is our object to guess whence the new plague comes. We prefer to correct a popular error about the bites. Vinegar is constantly recommended as an application; but from personal experience in our foreign travels we can declare that an alkali is far better. A strong solution of carbonate of soda will allay the pain and itching set up by the mosquito poison, sooner than anything.

The most effectual lotions sold in the localities where those insects abound all contain an alkali.

Marshall Hall Fund.

The subscribers met last Wednesday, and resolved to have a medal bestowed, together with the title of "Marshall Hall Scholar" every five years. The Medico-Chirurgical Society is to be entrusted with the duty of carrying out the scheme. It was at first thought that the Royal Society would undertake it, but that body seems to be unable to see its way clearly to accept the trust. The Medico-Chirurgical Society will be equal to the occasion.

Albrecht von Graefe.

The great master is dead. Europe—the world—has lost the greatest oculist in the prime of his life, struck down by phthisis, that destroyer of so many of the great and noble. We have, it is true, in England many of his pupils, while France and other countries have also learned from the great German, and all are proud to acknowledge themselves his disciples, as they all lament the loss of one to them personally attached, as he was to so many thousands whose sight he has been the means of restoring.

The Sanitary Act (1866) passed the third reading in the House of Commons on Wednesday last.

Tests of Death.

M. Laborde has read before the Academy of Science a communication on a new means of determining the existence of death. He points out that when a finely polished steel needle is plunged sufficiently deep into the tissues of living animals, at the end of a variable but usually short period, the needle loses its metallic tissue to a greater or lesser extent and becomes oxidised. If, on the other hand, such a needle is introduced into the muscular tissues of a dead body and left there for twenty minutes or an hour it remains perfectly untarnished. The oxidation of the needle and the themic and electric conditions to which it is subjected constitute, according to M. Laborde, a constant and reliable sign that the death is only apparent.

Variations in Maternal Milk.

M. Louis Sourdat has addressed to the Paris Academy of Sciences an observation on the unequal production and differing composition of the milk from two breasts of the same woman.

Having noticed the very remarkable preference manifested by the infant for the right breast of its mother—a preference shown by two previous children—and having at the same time made the remark that the right breast was much larger than the other, and gave double the quantity of milk, he thought it worth while to make examination of the milk from each. He arrived at the following conclusions:—

1. The composition of the milk produced by the two breasts, taken together, is from day to day very variable, although there be no appreciable change in the state of health. But temporary fatigue, or change of diet, or the keeping of the milk in the breasts, is sufficient to cause this difference. Thus, in analyses, the dried residue varied from 10 to 13·70 per cent. The density was also very variable. He obtained for the mean of the two breasts specific gravities varying from ·980 to 1·031.

2. The composition of the milk varied materially in each breast. Thus, that of the right breast, in addition to being much more plentiful, was also richer in the ratio of 1·20 to 1 for a minimum, to 1·74 to 1 as a maximum.

3. In these conditions the butter was usually secreted in a much greater quantity in the right breast, in the ratio of 1·50 to 1 (minimum), and 9 to 1 (maximum).

4. Azotized substances, such as caseine and albumen, were also secreted in much greater quantity in the right breast, in the proportion of 1·90 to 1.

5. The soluble principles, lactose and salts, were found to be secreted almost equally in each breast.

The Ambulances of the French Army.

The Union Medicales announce authoritatively the arrangements for the Ambulance Service of the French Army, as follows:—

The principle adopted by the Medical Service will be to avoid as much as possible the removal of persons suffering from gunshot fractures, and to treat them as near as possible to the battle field. To carry out this intention each ambulance corps will be comprised of a moveable ambulance with hospital tents placed in a neighbouring village. The service of the ambulance, sufficiently numerous to

deal with the requirements which are expected to arise, will be available at the ambulance, and a reserve comprising the officers, the students, and hospital sergeants will convert the ambulance, when required, into a temporary hospital, leaving the corps ready to follow the army. The organization of each ambulance will consist of a surgeon in chief, four surgeons, ten assistant surgeons, twelve assistants, a commissariat officer, and a chaplain, in addition to its camp followers, the nurses, and baggage guards.

The principle which will be pursued in filling up these offices will be as follows:—

The assistants will be taken from the students in medicine; the assistant surgeons from amongst French surgeons and resident pupils who can produce evidence of knowledge and experience. The surgeons will be chosen from the best of the assistant surgeons according to rate of promotion.

Nature has reason to believe that Professor Sir William Thompson will be the next President of the British Association.

We have the satisfaction to announce that, in spite of the opposition of a contemporary, Dr. Orange has been elected Superintendent to the Broadmoor Lunatic Asylum.

The will of Thomas William Burt, Esq., M.D., formerly surgeon in the Hon. E.I.C. Bengal Medical Establishment, and late of No. 2 Obere, Promenade, Homburg, Prussia, was proved in London, on the 7th inst., and the personalty in England sworn under £30,000.

Dr. Eustace Smith has been appointed Physician in ordinary to H. M. the King of the Belgians, and has had conferred upon him, the honour of Chevalier of the Order of Leopold. This appointment does not require Dr. Smith to relinquish his London practice.

However distressing and painful the occurrence of decapitation in the late execution in Dublin must be, it seems to us that neither the ferment of the *Irish Times* nor the contemptible anti-Irish philippic of the *Pall Mall Gazette* was at all justified by the circumstance.

Animated by feelings of compassion for the unfortunate criminal, whom it was no part of the law's desire or right to torture, the authorities appear to have adopted a principle in the carrying out of the execution which turns out in the light of experience to have been incorrect, and we think their error has been the result of perhaps an overstrained sympathy with the condemned convict.

The length of the rope used in the execution was 14 feet, a length greatly in excess of what had been previously employed, except on one recent occasion. So long a drop had been adopted on purely scientific principles. In the *Philosophical Magazine* for 1866, a communication from Professor Haughton is printed, which deals with the subject on mechanical grounds. In it Professor Haughton says that he "has searched in vain for well authenticated instances of fracture of the vertebra," and he notices the results of *post-mortem* examinations in two cases where the fall had been respectively 7½ and 11 feet, in neither of which dislocation or fracture had taken place. He, therefore, assumes that the ordinary fall of three or four feet is sufficient only to cause strangulation, and considers that the torture of death by this means must be great. He proceeds to say—"It has been ascertained by me that the shock of a ton dropped through one foot is just sufficient to fracture the anterior articulating surfaces of the second vertebra at their contact with the atlas, and that this force allows the shock to fall on the medalla oblongata so as to produce instantaneous death." Acting on this supposed fact, Professor Haughton gives the following formula:—"Divide the weight of the convict in pounds into 2,240, and the quotient will be the required length of drop." Professor Haughton does not say by what process he arrived at the conclusion that a force of a ton falling one foot is no more than sufficient to break the neck; but we presume he must have assured himself of the fact by experiment. Since the publication of this paper one convict was hung with the long drop, and on *post-mortem* examination it was found that the superior articulating surfaces of the vertebra were fractured near the posterior border, and the shock had been sufficient to extend the convict's neck by 1½ inch. In his evidence at the inquest which was held immediately after the execution—

Dr. Humphrey Minchin said, I am surgeon to the Richmond Bridewell, and, in compliance with the Act relating to the carrying out of capital punishment within prisons, I was present at the execution of William Carr on the morning of the 28th July, 1870; I have since made a *post-mortem* examination of the body; the head was completely severed from the trunk, all the parts being divided equally across; the second cervical vertebra was fractured, which alone would cause instantaneous death; it would be difficult to account for the cause of the decapitation on ordinary principles; the fall which he got was less in proportion to his height than the fall Kilkenny got at Kilmainham. The fall is a matter simply of figures; death by strangulation is caused by a short rope with all the attendant horrors of kicking and struggling; whereas a long rope insures a sudden, instantaneous, and painless death, by fracturing or dislocating one of the bones of the neck; a portion of the force of the fall is usually expended in tightening the elaborate noose usually employed, whereas, in the present case, I fear that the noose was tightened beforehand, and thus an additional force was reserved which resulted in separation of the head; the usual formula is 2,240lbs, which, divided by the weight of the offender in pounds (in this case 159), will give a quotient, representing the number required to break the neck, which would be 14; in my opinion the immediate cause of death was a traverse fracture through the second cervical vertebra, and a displacement of the second from the third; the drop is 22 feet from the ground, and the man fell 14 feet; I do not think the thinness of the rope contributed to the accident; I suggested 14 feet as a proper fall in accordance with the opinions founded on published scientific data, and with a view of avoiding a lingering and torturing mode of death. The rope did not give way.

The Quarterly Examinations of the Roaly College of Surgeons of Ireland have just concluded. For the first half, or primary anatomical examination, forty-five students were examined, of whom eleven failed to satisfy the examiners. On the second half, or surgical examination, forty-three presented themselves, of whom seven were rejected.

SCOTLAND.

EDINBURGH.

The Municipal Curators of the University of Edinburgh.—At a meeting of the Edinburgh Town Council, held on Tuesday the 26th July, Bailie Skinner, who was absent at the recent election to the chair of midwifery, read the letter which he had left for the curators recording his vote with his reasons. We give it *verbatim*, as it affords an amusing commentary on the remarks we made a few weeks ago on this subject.

"London, 28th June, 1870.

"Dear Sirs,—As I am just setting out for the Continent, and in all likelihood will not return in time to be present at the election by the Curators of a Profession to the Chair of Midwifery in the University of Edinburgh, I take leave hereby to record my vote in favour of Dr. Alex. R. Simpson, as a successor in that Chair to the lamented James Y. Simpson, Baronet.

"I have most attentively perused and considered the voluminous testimonials of the various candidates, and made personal inquiry of many professional gentlemen of eminence, in whom I have every confidence, as to the special qualifications of the competing candidates; and I have come to be of opinion that, as regards personal merits, aptitude for teaching, combined with scientific knowledge and professional skill, three of the candidates, viz., Dr. Kieller, Dr. Matthews Duncan, and Dr. A. R. Simpson, stand so very much upon a par with each other, that it is difficult to discriminate between them.

"This being the case, it has given me much pleasure to record my vote, as above, in favour of Dr. Alex. Simpson, for the following among other reasons:—

"1st. Because Dr. Simpson is the son of that worthy brother (still living) who was the acknowledged means of Sir James Simpson's professional success, from which the world has received, and will receive, a lasting blessing.

"2d. Because Sir James Simpson often expressed a wish that his nephew might succeed him in the Chair, as the person best fitted to continue and expound to the students his system of obstetrics. Added to this, Dr. Alex. Simpson will have the advantage of possessing his uncle's invaluable museum, medical library, diagrams, apparatus, and other appurtenances used in lecturing.

"3d. Because the *City* and *University* (reflected as these communities are in the Court of Curators), by electing Dr. Alexander Simpson, will pay the highest tribute of respect and gratitude to the memory of his uncle, and do honour to themselves by retaining the beloved name of 'Simpson' in connection with the Edinburgh University.—I have the honour to be, &c.

(Signed) "Wm. Skinner, Curator."

The Royal Maternity Hospital.—Dr. Matthews Duncan has been unanimously elected one of the ordinary physicians to this Hospital.

There is not much fever at present prevailing in Edinburgh, the cases occurring are almost relapsing.

GLASGOW.

The University.—The Queen has been pleased to contribute £500 in aid of the University new buildings.

ABERDEEN.

Royal Infirmary Aberdeen.—We are glad to see from the report of the meeting of the managers of this institution, that an effort has been made to attach certain wards to the chair of Surgery in the University. This is a step in the right direction, and we intend in a future number to call attention to the desirableness of having a prominent connection established between the University and the Infirmary.

We learn from the *Aberdeen Free Press*, of 19th July, that the Medico-Chirurgical Society of Aberdeen has declined to express any opinion on the subject of the recent appointment to the chair of midwifery in Edinburgh.

We regret, not that it has so determined, but that its decision should have been announced in the journal referred to in terms which are painfully derogatory to the society as a scientific body, and prejudicial to the dignity of the medical profession in Scotland.

Dr. Alex. Ogston has been appointed surgeon to the Aberdeen Infirmary, in room of Dr. Keith, resigned.

Correspondence.

VACCINATION AND RE-VACCINATION.

LETTER FROM DR. CHARLES R. DRYSDALE

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I don't know if it has been remarked by yourself or most of your readers, how completely the present terrible mortality from that most fearful of all human diseases—small-pox—in Paris is proving the necessity of adult re-vaccination. The fact that many of my acquaintances and coadjutors in attempting to repeal certain Acts—the Contagious Diseases Acts, 1866-69—which I consider as useless and unjust, being unconvinced as to the merits of vaccination, is a reason for me troubling you to prove a fact which you doubtless think as already but too evident.

The actual epidemic of small-pox, according to the Committee of which M. Tardieu was president and M. Latour secretary, commenced in the month of November last. In that month there were 93 deaths from small-pox in Paris: in December 119. From the 1st January, 1870, to May 24th, 4,250 cases of small-pox were taken into Parisian hospitals. Of these 683 died—about 14 per cent. In former days the mortality from small-pox was about one-fourth of those attacked, and half-a-million persons were said to have died annually of this disease in Europe at the latter end of the 18th century. But in the French army every soldier on entering the ranks is re-vaccinated or vaccinated, and from the 1st January to 27th May, 1870, of 13,050 patients of the Val de Grâce military hospital at Paris, there were but 116 cases of small-pox, although Paris was full of small-pox contagion. Only four of these died. Of these 116 small-pox cases 96 had been vaccinated in infancy, 13 re-vaccinated with effect, 3 without effect; 7 had not been vaccinated, and one of these died. In former days small-pox sometimes killed as many as 80 per cent. of hospital cases, and was the greatest and most horrible of all plagues.

If those gentlemen, such as Mr. F. W. Newman, and even some of our own ranks, who are so much opposed to vaccination, would read the Army Medical Report Blue Book for 1868, just published, they would find in some cases—as for instance, in Scotland in 1868—not a single case of small-pox occurred among the soldiers in that year. In Ireland, owing to the admirable manner in which the Poor-law medical officers perform their functions as public vaccinators, small-pox has been literally "stamped out." In the ten years ending 1841 no less than 58,000 persons died from small-pox in Ireland, and thousands were disfigured by it. During the next ten years, ending in 1851, the figures fell to 38,274, and from 1851 to 1861 to 12,727. In the year 1866 only 187 persons died of the disease in Ireland, and in 1867 only 26 persons. It is said now to kill scarcely anyone in Ireland or in Scotland.

One of the anti-vaccinators, a gentleman whom I have great esteem for, begged me to consider, in a conversation with him, that consumption was now the prevalent disease instead of small-pox, and maintained (with Dr. Copland, I think) that this disease was caused by the prevalence of vaccination. Of course, in such a difficult science as that of medicine, it will always be impossible to silence such objections. The *post hoc ergo propter hoc* reigns supreme in physiology, as it does in social science; but I would just ask our friends, who assert that vaccination is the cause of consumption, how they make out their theory? I have remarked that black races die very rapidly of consumption, just as white soldiers do under the same circumstances, when shut up in unventilated barracks, and that the richer classes in this country, all of whom are vaccinated, do not die so much of consumption as the poorer classes, who are ill-fed and ill-cared for, although the latter are certainly not so universally vaccinated as the rich.

That one child in ten thousand vaccinated showed fever and died, is but a poor argument against vaccination. All diseases are apt to cause slight disturbances and occasionally to destroy life. That one child in half a million vaccinated should have syphilis from it, but proclaims the necessity for care in selecting the vaccine matter, and this seems not to be difficult, since such cases scarcely ever occur in Britain. The last question in compulsory vaccination is the question of individual liberty. I am quite ready to confess that Government, or society, has no right to compel a grown up person to be vaccinated, or to abstain from alcohol, if he or she objects to it on good or bad grounds; but neither in the matter of education nor vaccination can I admit that parents have paramount rights over the lives of their children. In the days of Ancient Rome a father had power over the life of his children. Now-a-days society cares more for the individual than for the family, and parents must learn the needful lesson that there is no reason because they have, wisely or unwisely, brought a new member into the State, that they are to neglect the best interests of that citizen, either from want of knowledge or from supineness. These are the reasons why I am in favour of compulsory vaccination of children. I should be glad if Mr. Newman would reply.

I remain, Sir, yours, &c.,

CHARLES R. DRYSDALE, M.D., M.R.C.P., F.R.C.S.E.

THE CONTAGIOUS DISEASES ACTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—With your wonted impartiality, I hope you will permit me to return to the subject of the *Contagious Diseases Acts* in reply to the communication of your eminent correspondent, Dr. Charles Drysdale; and before doing so I would fain endorse Dr. Drysdale's remarks respecting the liberality and honesty of principle, which forces itself upon every observant member of the Profession, with which the MEDICAL PRESS AND CIRCULAR is conducted. I must at once admit, and I am not at all ashamed in being corrected by such a physician as Dr. Drysdale, that in using the word *virtue* I meant to imply *chastity*: I should be sorry to be understood by followers of the Bentham School that, in saying the Irish were virtuous, I conveyed they were happy. It would be a somewhat complex matter to understand any people living under unjust laws, and subject to the ignominy of a conquered race, being contented or happy. There is no truer friend of Ireland than Dr. Drysdale himself. Recent writings of his own, wherein the Irish Celt was contrasted with the Anglo-Saxon race, met not only with enthusiasm in Ireland, but were uproariously received by our brethren in America. I am truly proud to learn that a gentleman of Dr. Drysdale's culture and acknowledged ability, after correcting me in the use of the word "virtue" and substituting chastity instead, should so freely admit that the Irish are a "chaste race." If it be so they belong to the Church of the majority in Ireland, which our learned French *confrère* designates absurd, and whose doctrines he considers it so very difficult to comprehend. I am no advocate for priestly terrorism, and no one despises the petty tyrant in the sheep's clothing more than I do, so that I may at once assert I believe it is not owing to the men who inculcate certain doctrines, but that it is true religion itself existing in all its purity and strength in Ireland that keeps the people chaste and from prostitution. As it is the nature of Frenchmen to thirst for war, for Irishmen to continue disaffected because of grievances which require to be redressed, so is it the nature of other nations to be depraved and rife with contagious disease, infanticide, &c. If M. Lefort's assertions, respecting the difficulty of understanding the doctrines of the Catholic Church were true, the Church of the minority in Ireland should show a comparative diminution in the number of prostitutes, but it will be found quite the reverse. The Church of the majority has the least. I am no advocate for the *Contagious Diseases Acts*. Captain Vivian, who opposed the repeal of the Acts in the House of Commons, and who would, doubtless, go hand in hand with Dr. Drysdale regarding greater facility in obtaining divorce, could tell that it is the nature of the English nation to be only too ready to break through every dogmatic rule of morality, and that, if prostitution were put down with an iron hand by the State it would exist and flourish in secret.

No one can dispute the importance of Dr. Drysdale's teachings respecting large families, but how many men of such prudence and self-denial are there to be found likely to practise it? The treasurer of the Poor Curates Fund I dare say could tell some valuable practical lessons of the utility of such a doctrine, even if only practised by the clergy of the Church of England.

I cannot refrain stating, however high my opinion of Dr. Drysdale may be, and my profound respect for him as a gifted physician is truly great, that in my humble opinion greater facility of divorce will not obviate the evil of prostitution and contagious disease. I should be afraid of it increasing it. Depraved wretches would take advantage of it and prove the ruin of many women. Our existing laws on the subject alone deter him. In some districts we find where the people are too poor to pay the costs of a divorce they agree by mutual contract to separate, and practise their depravity *sub rosa*, but our experience is that it seldom proves salutary to any party. Suppose there were no legal restriction and marriage were a farce, society would be in a pitable condition.

I am, Sir, your obedient servant,

J. WARING-CURRAN.

Osman House, Sutton, Notts, July 28th, 1870.

A NEW IODINE PAINT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have been requested by some professional *confrères* to bring under the notice of the profession, a new *iodine paint*, which I have had prepared and used with satisfaction and success, in the cases of glandular enlargements and scrofulous diseases, wherein iodine is called into requisition. In the hands of esteemed and eminent practical surgeons, it has proved equally beneficial as in my own practice, and they speak or write in flattering terms of it to me.

I rub down half-an-ounce of iodine and a like quantity of iodide of ammonium in a Wedgwood mortar, and gradually dissolve it in twenty ounces of rectified spirit; to this I add four ounces of glycerine, shaking the solution well together. A very nice paint is thus obtained, which has the following advantages:—

1. The iodine is prevented escaping owing to the combination which, in the form of ordinary tincture, in warm weather it is very apt to do.

2. It preserves the iodide of ammonium instead of the iodide of potassium; the former being a more powerful absorbent than the latter, which recent investigation has verified.

3. The action of the glycerine is soothing to the skin, keeping it soft and pliable, a contrast to the shrivelling of cuticle produced by the ordinary tincture in common use, which frequently acts as a vesicant. But where absorption is desired, the part affected and its neighbourhood influenced, as well as the system generally, by iodine, and no local irritation required, this combination in form of paint will be found superior to the old tincture.

Some time ago, in the columns of the MEDICAL PRESS, I gave a history of very extensive bronchoceles met with in the Valley of Rossendale, which were reduced by the iodide of ammonium, exhibited internally as well as locally applied in form of citrate. Since then I have seen parallel cases in Derbyshire, which were much benefited also by the combination of iodine, iodide of ammonium, and glycerine to which I now direct attention.

I have not confined the use of the preparation alone to glandular swellings or scrofulous gatherings. I have employed it in chronic cutaneous diseases, to nodes, over enlarged livers, diseased joints, to hypertrophied parts or morbid growths, and in cases wherein it was necessary to alter an abnormal action or promote absorption, and the result was uniformily satisfactory, and I think I may safely say, the effect of the iodine was more readily appreciable, and more quickly demonstrated in its action on the system generally, as well as by its absorbent properties locally, than the old tincture of the British Pharmacopœia, *minus* its disadvantages.

I am, Sir, your obedient servant,

J. WARING-CURRAN.

Osman House, Sutton, Notts, July 22nd, 1870.

BATHING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—"Is it right for 'orrid little boys to bathe in the river?" is a thought that must have occurred to thousands as well as myself whilst journeying up and down "between bridges" on the Thames. If it is wrong let the Medical Profession speak against it and the authorities rigorously repress it; but if desirable, now that so much is being done to improve our great river and utilize its banks, let the Government, while spending so much money, pay a little more to provide, not little boys only, but all ages and both sexes of our huge population with suitable, economical, health-giving, *decent* and *safe* opportunities of obtaining cleanliness and beneficial open-air bathing and swimming, either by proper structures (combined with strict regulations as to dress, attendance, &c.), as provided at Biarritz (Basses Pyrenees, France, where the establishments belong to the municipality, and are a considerable source of revenue), to be built at proper distances along the Embankment, or else provide for the formation of "Ecoles de Natation," as in Paris. Perhaps some of your readers will develope or utilize this hint.

ALBERT HIND.

July 25, 1870.

SPIRITUALISM VIEWED BY THE LIGHT OF MODERN SCIENCE.

MR. WILLIAM CROOKES, F.R.S., has published an article in the *Quarterly Journal of Science*, entitled "Spiritualism Viewed by the Light of Modern Science." Mr. Crookes is the editor of the *Chemical News*; he is recognised as one of the most accurate observers possessed by the Royal Society, and it was he who discovered the new metal "thallium" by the aid of spectrum analysis.

We extract from the communication some of its most important statements. Mr. Crookes says :—

"A man may be a true scientific man, and yet agree with Professor De Morgan, when he says—I have both seen and heard, in a manner which would make unbelief impossible, things called spiritual, which cannot be taken by a rational being to be capable of explanation by imposture, coincidence, or mistake. So far I feel the ground firm under me; but when it comes to what is the cause of these phenomena, I find I cannot adopt any explanation which has yet been suggested. The physical explanations which I have seen are easy, but miserably insufficient. The spiritual hypothesis is sufficient, but ponderously difficult.

"Regarding the sufficiency of the explanation, I am not able to speak. *That certain physical phenomena, such as the movement of material substances, and the production of sounds resembling electric discharges, occur under circumstances in which they cannot be explained by any physical law at present known, is a fact of which I am as certain as I am of the most elementary fact in chemistry.* My whole scientific education has been one long lesson in exactness of observation, and I wish it to be distinctly understood that this firm conviction is the result of most careful investigation. But I cannot at present hazard even the most vague hypothesis as to the cause of the phenomena. Hitherto I have seen nothing to convince me of the truth of the 'spiritual' theory. In such an inquiry the intellect demands that the spiritual proof must be absolutely incapable of being explained away; it must be so strikingly and convincingly true that we cannot, dare not, deny it. No observations are of much use unless they are truthful and made under test conditions; and here I find the great mass of Spiritualistic evidence to fail. In a subject which, perhaps, more than any other lends itself to trickery and deception, the precautions against fraud appear to have been, in most cases, totally insufficient, owing, it would seem, to an erroneous idea that to ask for such safeguards was to imply a suspicion of the honesty of some one present. We may use our own unaided senses, but when we ask for instrumental means to increase their sharpness, certainty, and trustworthiness under circumstances of excitement and difficulty, and when one's natural senses are liable to be thrown off their balance, offence is taken.

"In the countless number of recorded observations I have read, there appear to be few instances of meetings held for the express purpose of getting the phenomena under test conditions, in the presence of persons properly qualified by scientific training to weigh and adjust the value of the evidence which might present itself. The only good series of test experiments I have met with were tried by the Count de Gasparin, and he, whilst admitting the genuineness of the phenomena, came to the conclusion that they were not due to supernatural agency.

"The pseudo-scientific Spiritualist professes to know everything; no calculations trouble his serenity, no hard experiments, no long laborious readings, no weary attempts to make clear in words that which has rejoiced the heart and elevated the mind. But, where every step is towards the marvellous and unexpected, precautions and tests should be multiplied rather than diminished. Investigators must work; although their work may be very small in quantity if only compensation be made by its intrinsic excellence.

"The Spiritualist tells of bodies weighing 50 or 100 lbs. being lifted up into the air without the intervention of any known force; the scientific chemist is justified in asking that a power, professing to be guided by intelligence, which will toss a heavy body up to the ceiling, shall also cause his delicately poised balance to move under test conditions.

"The Spiritualist tells of flowers with the fresh dew on them, of fruit, and living objects being carried through closed windows, and even solid brick-walls. The scientific investigator naturally asks that an additional weight (if it be only the 1,000th part of a grain) be deposited on one pan of his balance when the case is locked. And the chemist asks for the 1,000th of a grain of arsenic to be carried through the sides of a glass tube in which pure water is hermetically sealed.

"The Spiritualist tells us of manifestations of power, which would be equivalent to many thousands of 'foot-pounds,' taking place without known agency. The man of science, believing firmly in the conservation of force, and that it is never produced without a corresponding exhaustion of something to replace it, asks for some such exhibitions of power to be manifested in his laboratory, where he can weigh, measure, and submit to proper tests.

"For these reasons, and with these feelings, I began an inquiry suggested to me by eminent men exercising great influence on the thought of the country. At first, like other men who thought little of the matter, and saw little, I believed that the whole affair was a superstition, or at least an unexplained trick. Even at this moment, I meet with cases which I cannot *prove* to be anything else; and in some cases I am sure that it is a delusion of the senses. That the subject has to do with strange physiological conditions is clear, and these in a sense may be called 'spiritual' when they produce certain results in our minds. At present the phenomena I have observed baffle explanation; so the phenomena of thought, which are also spiritual, and which no philosopher has yet understood. No man, however, denies them.

In reference to the opinions thus expressed, Mr. Varley, the celebrated electrician, an earnest disciple of spiritualism, has addressed a letter to Mr. Crookes, in which he describes electrical experiments carried out by him for the purpose of investigating alleged phenomena. He says,—

"I have scarcely ever been able to induce mediums, through whom the physical phenomena occur, to consent to sit for accurate investigation. In 1867, Miss Kate Fox, the well-known American medium, agreed to sit with me in New York during a series of investigations into the relations between the known physical forces and the spiritual. A Grove's battery of four cells, a helix eighteen inches in diameter, electro-magnets, and other descriptions of apparatus were procured by me. The plan of action was as follows :—I was to go through a series of experiments, and the intelligences or 'spirits'—as they are usually, and I think properly, called—were to narrate what they saw, and

if possible to explain the analogies existing between the forces I was dealing with, and those which they employ. We sat eight or nine times for this purpose, but although great efforts seemed to be made by the spirits present to convey to my mind what they saw, it was unintelligible to me. The only positive results obtained were the following:—As we sat in the dark, and the manifestations were sometimes violent, I had taken the precaution to place the battery and keys on a side table, and led the wires from the "keys" or communicators, to the apparatus on the tables round which we sat, so that I could, in the dark, perform the various experiments I had arranged to try. Whenever, by accident, my hands came in contact with one of the wires, without my being aware which wire it was, I put these questions:—'Is a current flowing through it?' and if they said 'Yes,' I asked, 'In which direction does it flow through my hand?' This experiment was repeated, if my memory serves me rightly, not less than ten times. Each time, directly after being informed of the direction of the current, a light was struck, and in every instance I found we had been correctly advised, if we assume that the current flows from the positive to the negative pole.

"The experiments with the helix were of two kinds:—First, 'what action had the electrified helix upon me when placed over my head?' Secondly, 'when a piece of iron, or a compass needle, was placed inside it, could the spirits affect the magnetic action of the helix upon the iron or compass?' Repeatedly during the investigations, and while we were in the dark, I seized the opportunity of placing the magnetized helix over my head, and immediately, on each occasion, the spirits requested me not to do it, as it hurt me; nevertheless, I could feel no pain or sensible action myself. As no one but myself was aware that I intended to, or was placing, this helix over my head, it is perfectly clear that the fact was made known by some means inexplicable as yet by orthodox science.

We most cordially commend the high scientific spirit evinced by Messrs. Crookes and Varley in these inquiries. No amount of reiteration of pooh! pooh! can open the eyes of the public to the swindle, if it be one, or thrust out the truths of Spiritualism from the light of day, if there be phenomena worthy of notice. If men like Mr. Crookes grapple with the subject, taking nothing for granted, even under overwhelming re-assertion, until it is proved, we shall soon know how much—if any portion—of it, we are to believe.

If Spiritualists are neither dupes nor swindlers they have gone far to put themselves in either category, firstly, by concocting ridiculous attempts at explanation of phenomena; secondly, by involving their phenomena in a fusty fog of darkness and mystery; and, thirdly, by setting their faces against scientific inquiry.

We need no further proof of this latter accusation than the *naïve* confession of Mr. Varley:—

"I have scarcely ever been able to induce mediums, through whom the physical phenomena occur, to consent to sit for accurate investigation."

Medical News.

Royal College of Physicians of London.—The following members were elected Fellows of the Royal College of Physicians on the 28th ult.:—William Wadham, M.D., London; Samuel Martyn, M.D., Bristol; Adam Bealey, M.D., Harrogate; Stephen Henry Ward, M.D., London; Edward Clapton, M.D., London; William Cholmeley, M.D., London; George Britton Halford, M.D., Melbourne, Victoria; Edward Long Fox, M.B., Clifton; Edward Thomas Wilson, M.B., Cheltenham; Charles Elam, M.D., London; Arthur Julius Pollock, M.D., London; Henry Matthews Tuckwell, M.D., Oxford; Octavius Sturges, M.B., London; William Smoult Playfair, M.D., London; Henry Gowen Sutton, M.B., London; Samuel Fenwick, M.D., London; Sydney Ringer, M.D., London; Charles Hilton Fagge, M.D., London; William Selby Church, M.B., London; Samuel Jones Gee, M.D., London; Walter Butler Cheadle, M.D., London; Philip Henry Pye-Smith, M.D., London; Dyce Duckworth, M.D., London; Hy. C. Bastian, M.D. Lond. At the same meeting the following having passed the required examinations, were admitted as members:—I. C. J. Fenwick, M.B. Cantab., of London; E. Buchanan Baxter (Lic.) M.B. Lond., of London; Charles Kelly, M.D. Lond., of London; and Frederick Thomas Roberts, M.B. Lond., of Kensington.

Royal College of Surgeons of England.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 26th ult., viz.: Messrs. Alfred Henry Carter, L.S.A., Pewsey, Wilts; Doyle Granville, Gloucester road, N.W.; Martin Henry Payne, L.R.C.P. Edin. and L.S.A., Bridgwater; and William James Palmer, L.S.A., Great Yarmouth—students of University College; John Desborough Robinson, Syston, Leicestershire, of Charing Cross Hospital; John Dixon, Newcastle-on-Tyne; Henry William Webster, Tamworth, Staffordshire; and Charles Holmes, L.R.C.P. Lond., Ardwick—of the Manchester Royal School of Medicine and Surgery; Morgan Philip O'Leary, Ballintarmin, county Kerry, of the Dublin School; Antonio José Amadeo, M.D., Philadelphia; Porto Rico, of Philadelphia; Edwin Brownrigg Wood, Birmingham; and William Hugh Lambart, Liverpool—of the Birmingham School; Adam Young, Boston, Lincolnshire, of St. Bartholomew's Hospital; Frederick Peter Deshon, L.S.A., Coulston, Wilts, of the Middlesex and London Hospitals; Kristo Dhan Ghose, L.M. and S., Calcutta, of the Calcutta School; Henry Macready Chute, Bristol, of the Bristol School; Henry Ensworth Jackson, Highbury; and Samuel Stickland, New Charlton, Kent—of Guy's Hospital; James Robert Liston, Peckham; and Charles Jervis, St. John's-wood Park—of St. Mary's Hospital. The following candidates, who passed in surgery at previous meetings of the Court of Examiners, having since obtained medical qualifications recognised by the college, were also admitted Members, and received their diplomas, viz.: Samuel Evans, L.S.A., Llandovery, South Wales; William Renwick, L.R.C.P. Edin., Tyr Phil, Glamorgan; Henry Parmiter, L.S.A., Dorchester; Edward Willis Way, L.R.C.P. Lond., Adelaide, South Australia; Arthur John Hogg, L.R.C.P. Edin., Ealing, Middlesex; Howard H. J. Nicholls, L.S.A., Kennington Park; William Watson Dove, L.R.C.P. Edin., Ledbury road, Bayswater; Richmond Leigh, L.S.A., Liverpool; and Henry Frederick C. Eagle, L.S.A., London Hospital.

University of London.—The following gentlemen have passed the Preliminary Scientific (M.B.) Examination. *First Division:*—Messrs. Edward C. Baber, St. George's Hospital; Albert B. Barrow and George H. Batterbury, King's College; Philip H. Carpenter, University College and Royal School of Mines; Eugene Cretin, St. Bartholomew's Hospital; Henry J. F. Groves and Henry Hetley, Guy's Hospital; Charles R. Bell Keetley, St. Bartholomew's Hospital; Edward Kennedy, B.A., Manchester Royal School of Medicine; John Lewtas, Liverpool School of Medicine; John Magrath and Bernard M. S. Roth, University College; James Shuter, St. Bartholomew's Hospital; Sydney H. Vines, Guy's Hospital; and Ernest W. White, of King's College. *Second Division:*—Andrew Dodson, Queen's College, Birmingham; George Garlick, University College; Francis G. Hamilton and Vincent D. Harris, St. Bartholomew's Hospital; Jean A. Hullard, University College; Arthur H. Jones, Private Study; William H. Lamb, Guy's Hospital; Thomas E. Maclean, University College; Edward M. Madden, King's College; Thomas S. Morley, Private Study; William J. Notley, B.A., University of Edinburgh; Frederick J. M. Palmer, Guy's Hospital; Henry E. Price, University and Regent's Park Colleges; James A. Rigby, Guy's Hospital; Thomas King Rogers, University College; T. Henry Sawtell, St. Bartholomew's Hospital; R. H. Ainsworth Schofield, Owen's College; John W. Taylor, Charing Cross Hospital; and Edward Wackerbarth, of University College.

At a Court of Examiners held on the 28th July, the following gentlemen having passed the necessary examinations, were admitted licentiates of the Society of Apothecaries, viz.:—Messrs. Robert Chalmers, of Glasgow; Edward Madely, of Kensington; Edwin Smith, of Birmingham; and Edward

Southee, of Canterbury. And at the same court the following passed the primary professional examination, viz. :— Messrs. B. Brindley, of University College Hospital; C. W. S. Deaken, of University College Hospital; T. R. Edmundson, of Guy's Hospital; G. H. Fosbroke, of Westminster Hospital; J. D. Harris, of St. Bartholomew's Hospital; W. A. Maybury, of St. Thomas's Hospital; R. H. Paterson, of Guy's Hospital; John W. Watson, of University College Hospital; and D. M. B. Wheeler, of Guy's Hospital.

Working Men's Fund for the Extension of the Queen's Hospital, Birmingham.—The third half-yearly report of the General Committees presented yesterday evening, shows that the amount received to this date is £2,878 3s. 9d., of which £729 15s. 4½d. has been paid by gentlemen, and others not belonging to the working classes. The contributions from workpeople during the third half-year have amounted to £43 18s. 9d. less than the first, and £95 6s. 0½d. more than the second half-year. The workpeople in 288 factories and workshops have paid to this fund since its establishment, in January, 1868, whereas only 203 subscriptions from bodies of workpeople were paid in last year to the five following local institutions collectively :—The General Hospital, the Queen's Hospital, the General Dispensary, the Eye Hospital, and the Children's Hospital. Such an example as this is highly commendable, and will, we trust, be followed by the working classes of other large towns.

East London Family Emigration.—Earl de Grey and Ripon's letter in the *Times* of Monday, on behalf of this fund, shows that in spite of harsh conduct towards our noble and self-sacrificing Profession, in the late debate on Medical Reform, we may yet hope to have his lordship's aid in some of the good works which depend upon us. Contributions will be received by the Countess de Grey, 1 Carlton Gardens, and we may hope that by another year the humanizing influence of the countess and her work may inspire the Earl with a desire to do justice towards our Profession.

The Sick and Wounded.—The care of these is the duty and joy of our Profession, which always practises neutrality and heaps its benefits on all. It is our pleasure then to record that a national committee has been formed in England to co-operate with those abroad in furnishing aid to sufferers from war. The Heir Apparent is president. The offices are at 8 Trafalgar square. There has also been formed a ladies' association to which every one will wish well, as no more appropriate sphere for female work exists. Contributions may be paid to the ladies of the association, or to Messrs. Ransom, Bouverie, and Co., 1 Pall-mall, East; Lady Lyell, 73 Harley street, W.; Mrs. Russell Gurney, 8 Kensington Palace gardens; Miss Florence Nightingale; Mrs. Lyell, 42 Regent's Park road; Mrs. W. Wilson, 24 Park square, Regent's Park, N.W.; Miss Shepley, 24 Park square, Regent's Park, N.W.; Mrs. James Reiss, 7 Cromwell Houses, South Kensington; Madame Lind Goldschmidt, Oak Lea, Wimbledon Park; Mrs. Salis Schwabe, 8 Clarges street, Piccadilly, W.; and Mrs. Spencer Percival Robbins, 5 James street, Westbourne terrace.

Bachelor?—The degree of "Bachelor" of Laws has been conferred by the Chicago University on Mrs. Kepley, wife of Mr. H. B. Kepley, of Effingham. This is better than lady "bachelors" of medicine.

NOTICES TO CORRESPONDENTS.

WERE THE PRIESTS OF ANCIENT EGYPT THE FIRST PHYSICIANS?

To the Editor of "The Medical Press and Circular."

Sir,—It appears to me that the readers of the Medical Press and Circular should feel most grateful to your talented contributor, Mr. Donovan, for having kindly supplied them with so much valuable information, the result of his profound research on this subject; truly brief, yet thoroughly comprehensive. The study of the classical history of physic, not only in the widest sense expands the intellectual capacities of the physician towards the reception of other more practical details, but, by the acquisition of the knowledge of the doctrines and practice of the ancients, suggest the fundamental structure of principles, many of which in our own days have been denominated *inventions* or *discoveries*, although in reality but the *re-introduction*, under brighter auspices, and guided by the superior advancement by a more enlightened age, of the practices of our forefathers, which, clouded by ignorance and superstition, have lapsed gradually into obscurity.

In connection with the subject at issue, it may be interesting to some who have not paid attention to the matter, to know that Mahomet not only practised medicine, but even wrote on the subject. Records which have been handed down from Abulpharagius (one of the most celebrated of the ancient Arabian physicians), acquaints us with the fact. He and his followers for several generations belonged to the sect of Empirics, which took its origin in Alexandria. About the same period (the latter part of the seventh century, A.C.) an Alexandrian priest named Aaron, wrote in the Syriac language a number of treatises called the "Pandects of Physic," which were afterwards translated into Arabic by a Syrian physician. It is also a remarkable fact that Mahometan mosques were always founded at the same time and place as hospitals and medical colleges, a custom first commenced by Rashid, the fifth Caliph of Bagdad, of the line of Abbas, and pursued by many of his successors.

Some little doubt exists on my mind regarding the correct interpretation of the word in the 50th chapter of the book of Genesis, which in the English version is translated *physicians*, as well as of the meaning which the translators intended to convey by the word they selected. Of this, however, after the revision of the Pentateuch.

I am, Sir, your obedient servant,

South Molton, Devon. Francis E. Clarke, M.B.

July 20th, 1870.

War Maps.—In addition to those noticed in our last, we have since received the 1s. 6d. map of Messrs. Johnston and Co., which, like most, if not all the others, represents that portion of the European continent within a given area of the seat of war; transferred from large maps to ston, and reprinted in colours on smaller sheets. There is one improvement in Messrs. Johnston's map which we do not find in the others. The little petty German States of the Confederation, not actually tributary to Prussia, although joined with that power against France, are printed with a different tint, whereas the other maps give the whole of Germany in one colour, which makes them less distinct for tracing purposes. We can highly recommend Messrs. Johnston's map.

Ionorans.—It is held by high authorities that the second eight days in the intermediate period are safe. The proofs of the statement are not conclusive, and it may be dangerous to proceed on an assumption of its truth. The subsequent week is considered peculiarly hazardous.

Baby-Farming.—As to "A. B.'s" letter in the *Times*, a correspondent could not help regretting, when he read that letter, that so much zeal as the writer exhibited in the cause should be allied with so little discretion and delicacy of feeling in carrying out the inquiry. He is greatly astonished that the *Times* should have given space to such a letter. The way in which "A. B." enlisted the co-operation of an ignorant servant, and the possible effect upon that servant's mind, with the gossip which the affair would cause throughout the household, seemed all most objectionable,—unwise in the extreme on the writer's part. I am glad "A. B" has been reproved through your columns. It is such indiscreet women who bring discredit upon their sex, and one cannot help regretting that so much energy and courage should be wasted upon a woman who has so little share of womanly instinct to guide such noble and valuable qualities aright.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

The American Journal of the Medical Sciences. The Monthly Journal of Dental Science. Le Mouvement Medical. The Homœopathic Review. Science Gossip, &c.

VACANCIES.

Holborn Union (London) Workhouse—Medical Officer and District Medical Officer. Salaries, £150 and £105 respectively.

Great Northern Hospital, London—Surgeon. Must be F.R.C.S.

Anglo-American Telegraph Company—Medical Officer for Newfoundland. Salary, £300.

St. George's Dispensary, London—Physician-Accoucheur and a Surgeon. Honorary.

Bournemouth General Dispensary—Resident Surgeon. Salary, £100.

North Wales Counties Lunatic Asylum—Assistant Medical Officer. Salary to commence at £80, with board and residence.—[See advt.]

Birmingham Workhouse—Medical Officer. Salary, £200, with residence, &c.

APPOINTMENTS.

Badge, Dr. N., Assistant Medical Officer to the *Hamadryad* Hospital Ship, Cardiff.

Bellamy, E., F.R.C.S., Assistant-Surgeon at Charing-cross Hospital.

Butler, Mr. F. W., Assistant House-Surgeon to the Westminster Hospital.

Cockcroft, G. E., M.R.C.S., Medical Officer for the Hurworth District of the Darlington Union.

Godson, C., M.R.C.S., Surgeon-Accoucheur to the Lying-in Hospital, City road.

Hay, Dr. P. G., Assistant Medical Officer at the Aberdeen Royal Lunatic Asylum.

Orange, W., M.D., Medical Superintendent of the Broadmoor Lunatic Asylum.

Power, H., F.R.C.S., and B. J. Vernon, F.R.C.S., have been elected Ophthalmic Surgeons at St. Bartholomew's Hospital.

Ruxton, J., M.B., Junior House-Surgeon to the Preston and County of Lancaster Royal Infirmary.

Snow, H. L., M.B., House-Surgeon to the South Staffordshire General Hospital.

Steven, A., M.D., Medical Registrar at the Hospital for Sick Children, Great Ormond street.

Underhill, Dr. A. S., Resident Medical Officer at the Birmingham and Midland Free Hospital for Sick Children.

Whitcombe, E. B., M.R.C.S., Assistant Medical Officer to the Birmingham Borough Lunatic Asylum.

Wills, Mr. C. J., Assistant House-Surgeon to the Northampton General Infirmary.

Marriages.

Clothier—Carr.—On the 13th ult., at Tiverton, Henry Clothier, M.D., to Mary Elisabeth, daughter of Isaac Carr, Esq.

Hopkins—Smith.—On the 23rd ult., at St. Mary's, Bryanstone square, Alfred Boyd Hopkins, M.R.C.S., to Frances Eliza, third daughter of J. E. Smith, Esq., of Gloucester place, Portman square.

Irvine—Edie.—On the 19th ult., at St. Silas, Liverpool, John W. Irvine, M.D., to Mary, widow of John Edie, L.R.C.S.Ed.

Reed—Instone.—On the 13th ult., at St. Paul's Church, Hammersmith, Samuel Cartwright Reed, M.D., of Fulham, to Florence, only daughter of S. Instone, Esq., of Acton.

EXPERIENCES OF A REGIMENTAL SURGEON IN INDIA.

By C. A. Gordon, M.D., C.B.,

Deputy Inspector-General of Hospitals.

(Continued.)

Constable, 10th Foot, aged thirty-seven, sixteen years in India, admitted at Dinapore, 23rd August, 1857. Having, the day previous, returned to cantonments from service in Jugdespore jungles, where he had been much exposed to sun and rain, he was, at 3 a.m. of that day, suddenly aroused from sleep by severe griping and purging. At seven o'clock he was brought to hospital, and immediately received a carminative draught. His eyes were then sunken, the tongue cold, fingers somewhat corrugated; the early stage of cholera was distinctly marked, and a few minutes after his admission cramps in the abdomen and limbs had become intense. A sinapism was now applied to the abdomen; hot brandy in sago was administered; aromatic spirits of ammonia and sulphuric ether, each 20 drops, with 10 drops of tincture of capsicums, were administered every half-hour. In two hours after treatment had been commenced the symptoms began to moderate, leaving only exhaustion. No other remedy than a continuance of the carminative was required, and recovery was rapid and complete.

With regard to the *post-mortem* appearances in cases of cholera, I would here transcribe what I had observed so long ago as 1843-4, in reference to epidemics of the disease which visited the *Buffs* stationed at Allahabad in each of those years. My remarks on that occasion were that "in examining the bodies of those who have died of cholera we are struck with the absence of all appearances which, under ordinary circumstances, would account for death. We always find extensive congestion of the venous system, the right side of the heart being gorged with dark liquid blood; and, what is a remarkable feature in the disease is the total absence of those coagula in the heart, which are usually discovered after death from other diseases. The stomach and bowels are remarkably pale; their inner surface coated with soft ropy matter, as if it had been smeared over with thick mucilage. The stomach usually contains a greater or smaller quantity of the medicines that had been administered in the course of treatment, and the lower part of the intestinal canal is filled with the characteristic rice-water fluid. The gall bladder is distended with dark ropy bile, and the urinary bladder is invariably contracted and empty.

The occurrence of increase of temperature in the bodies of those who die of cholera, and of spasmodic actions, both continuing for a considerable time after dissolution, are phenomena which, from their very nature, commanded the attention of medical officers. They are by no means of invariable occurrence in those who die of cholera, nor are they confined to such, having been frequently noticed in the bodies of persons destroyed by yellow fever in the West Indies and South America; but, when they are first observed, and especially if witnessed by a near relation of the deceased, the impression produced is something appalling. I give an example:—

Case of Lt. Followes, 53rd Regiment, Calcutta, 1856. About ten years ago, while stationed at Cawnpore, he had a severe attack of cholera, his recovery from which he attributed to his having clandestinely drank nearly a bottle of brandy.

He ever afterwards retained a rooted fear and apprehension of the disease; but his health continued good until the arrival of his regiment at Fort William, where, during the latter part of January and all February, 1856, he was frequently awakened suddenly at night by an attack of diarrhœa, attended by "spasms" in the abdomen. He never mentioned these to anyone but a servant, who used to procure hot water as a pediluvium, as well as some brandy and tincture of ginger, and under this treatment the symptoms disappeared.

On 25th of February, 1856, he visited Dum Dum for the purpose of bringing back his wife, who was there on a visit. At breakfast he ate a large quantity of fruit, of

which he was particularly fond, partaking, among others, of oranges and pineapple.

During the rest of that day he felt uncomfortable, but looked unusually well—so much so that his friends congratulated him. At dinner he had no appetite, and contented himself with a plate of soup. He complained of drowsiness, and during the meal nodded several times, although such was not his usual habit.

In the evening, when returning, he fell asleep shortly after entering the "garry;" but after a time awoke, feeling dreadfully sick, and with an inclination to be purged. He had to rush out almost instantly, when he vomited profusely, and had a copious alvine evacuation. His wife, on his return to his seat in the conveyance, having expressed her alarm and fear regarding his state, he said,—"Oh! there is no fear of me; I have once had cholera, and could tell at once if I had that disease."

He had no further evacuation previous to his arrival at his quarters at about 10 o'clock (p.m.); yet, by that time he was so weak that he was unable to stand. From this time he was purged, and vomited six times before 3 a.m. Cramps took place in his legs, the pain from which became intense. These extended to his stomach (abdomen) and loins. Jactitation was constant—he turned from side to side, tossed his arms about, and groaned from pain. His voice was hollow; his fingers corrugated; features sunken; a dark zone beneath the eyes; the tongue and breath cold; the pulse fluttering, and at times imperceptible; the entire surface bedewed with cold clammy perspiration, which stood upon his face in large prominent drops. The spasms continued a considerable time after both vomiting and purging had ceased; as the vital powers decreased his jactitation diminished, and then during each accession he could only moan, while, in subdued voice, he ejaculated, "Oh, God! Oh, God!"

About four o'clock a.m. all bodily suffering ceased, and he fell into a deep sleep. The temperature of the surface now increased somewhat; the pulse beat more full and steady, and hopes were entertained that recovery might take place. Meantime, worn out with distress of mind and bodily exertion, his wife also dropped off in a slumber. About eight a.m. the pulse again began to flag—it rapidly sank, and then became imperceptible; the warmth of surface gradually became less, and, without awakening from his rest, he passed into death.

The widow awoke, and looked calmly at the body of her husband as it still lay upon its side in the attitude of sleep.

She knew not the change that had taken place, neither could she realise its truth when informed of it—and now came a scene most trying and heart-rending. She rushed to the corpse, threw herself upon it, while she burst into an agony of tears and hysterical sobs. Sympathy at such a moment was out of the question, and she was left unmolested to give vent to her first burst of grief.

In a few minutes, what was our horror to hear her scream—"Doctor, he moves, he moves!"—the last effort of muscular contractility showing itself in slight flexure of the fingers. In vain we endeavoured to convince her how delusive were her hopes of returning animation. "But he's getting warm," she sobbed, while she looked at us imploringly, "and must be alive." We had to point out that this peculiar phenomenon was also one of the fearful malady that had just claimed its victim.

It was difficult to form a theory capable of accounting for these phenomena, and I question if any satisfactory explanation has yet been given in regard to them. I will only quote the opinions of two eminent authorities:—Dr. Carpenter observes* that "Muscles possess the inherent property of contractility, yet are dependent upon the nerves for the exercise of that power." . . . . "This contractility may remain for some time after the nerves have ceased to be able to convey to them the effects of stimuli;" and then goes on to remark that "whilst the irritability of muscles is gradually departing after death, it not unfrequently shows itself under a peculiar form." . . . . "the most remarkable manifestations being witnessed after death from cholera and yellow fever, the muscular contractions in such cases being frequently spontaneous, and sometimes give rise to movements resembling the ordinary actions of the living state." Dr. Carpenter further quotes from Dr. Dowler, of New Orleans, various illustrative cases, in one of which this contractility continued upwards of four hours after death in a fatal case of yellow fever, in allusion to which it was remarked that "many circumstances indicate that these movements were due to the inherent contractility of the muscles, and were not in any degree dependent upon the operation of the nervous system."

Referring to the increased bodily temperature after death in connection with *post-mortem* muscular contractility in these two forms of disease, he makes allusion* to the general fact, to which, however, there are numerous exceptions, that increase of bodily heat during life usually attends accelerated pulse, and decrease of temperature those affections in which the pulse is slow, although there are numerous exceptions. He observes that "it is not a little remarkable that the temperature of the body should sometimes rise considerably after death;" and he gives a table, according to which it would appear that in some cases of disease the temperature of the thigh and epigastrium rose to 111° Fah. and 113° Fah., at the same time that the heat of the brain was only about 100°. He, however gives no explanation of the phenomenon. He merely records it.

Professor Houghton would appear to be of opinion that the continuance of muscular motion and the occurrence of increased temperature after death "tend to prove that the impeded circulation, which is the prominent symptom in cholera collapse, is due to the constriction of the capillaries, in consequence of which the muscles are deprived of their supply of freshly oxidized blood, the result of which is necessarily contraction and cramp, which produces the excessive agony and cramp that characterises the disease."†

I regret much my inability to perceive that these observations contain anything approaching a sufficient explanation of the phenomena alluded to, and more especially of their occurrence, particularly in bodies of the dead, by only two diseases, namely, cholera and yellow fever. A similar increase of temperature is said to be sometimes observed in the bodies of those who die by tetanus.

The latest reference to this subject occurs in the *Lancet* of 1st January, 1870, where *post-mortem* temperature is briefly discussed. It is there stated that, respecting the cause of the phenomenon, one set of observers attribute it to *solidification* (rigidity of the muscles), others, to the continuance of *vital* action after the motion of the heart has ceased; but it is apparent that neither of these *explanations* affords any real clue to the ultimate conditions upon which it depends. The subject, however, is one of great interest and importance, and will, it is hoped, be fully investigated.

CASES IN PRACTICE.

By R. L. Johnson.

The wife of George B., residing in Westminster, stopped me by a footway of the neighbourhood on a certain occasion, and, in words beseechingly pathetic, implored my assistance to relieve her husband, a labourer, who was "knocked idle on account of his back." She would not have intruded on me, she said, but for the fact of their large family; and, as I happened to be in the neighbourhood, she thought I might try and do something for him.

I accompanied Mrs. B. to her residence, where I found her husband sitting in a semi-erect position, and in great agony. He complained of intense pain on the right side, in the "small of his back;" he had been ailing for a month, and had become worse daily since that time. He was losing flesh, sleep, appetite, and heart. He had been cupped, blistered, poulticed, and had taken "stuff;" but the relief experienced was only slight and temporary. Little exertion gave him great pain, and the position in which I found him on my arrival at his residence rested him most, and afforded him the only ease he experienced.

I caused his cotton and his flannel shirts to be removed. Ocular demonstration revealed nothing abnormal at the seat of pain; but, on running my fingers over the part, and applying a moderate amount of pressure, I found a substance seemingly semi-elastic, of about two and a half inches long, and half an inch in diameter, lying beneath the skin, and over the latissimus dorsi muscle, four inches above the crest of the ilium, and two inches from the lumbar vertebræ. This substance rested parallel to the course taken by the fibres of the lumbar aponeurosis—more deeply situated—and permitted a small amount of displacement each time I raised the skin over it, or attempted by finger and thumb manipulation to diagnose its nature and structure.

During the time of examination my patient suffered acutely; but, as he "felt confident I'd do him no harm," he bore his sufferings pretty well.

I concluded there was a foreign substance beneath the skin, but my difficulty to remove it appeared almost insurmountable, for I was without a pocket case, and a stranger in the neighbourhood!

I represented to my patient and to his wife the peculiar position in which I was placed. "The cause of your great sufferings," I said "appears to be very easily removable; it evidently lies not very deep below the skin—one little cut, and most of the anxiety and the pain would undoubtedly leave you; but, unfortunately, I have no pocket case with me, what shall we do? I have a keen cutting pocket-knife; but that——" "Ah, it might do; try it, Doctor," said Mrs. B., breaking up my sentence. "Eh, George, don't you agree?" "Oh, I agree to anything but the continuance of the pain I suffer," my patient responded.

Instinctively, I placed my fingers in a pocket of my vest, and removed from it the knife, and with it my *latch key*. I was about to replace the latter when a rather original notion entered my head. It was to cause the latch key to become an important agent in my little operation, and thereby likely to lessen considerably the limits of my knife's action; for, I just remembered that, as my fingers travelled towards the *ends* of that body on whose removal I became now heroically resolved, they appeared to become small and very definable. Consequently, I determined to try and force into the pipe of the latch key one end of the body to be removed, by depressing the opposite end of it as I forced; then to depress the key end, as I may be permitted to call it, grasp the skin, and force the opposite end; then to make a small incision through the skin over this end, and still use force sufficient to enable me to grasp the foreign body, and finally draw it through the opening. Well, I succeeded in applying the latch key as I intended; but, although the opposite end of the foreign substance pressed against the skin sufficiently to permit me to define its exact position, and to puncture the skin; still, the pain to my patient was so intense, and the difficulty of forcing the point of the foreign body to the surface so considerable, that I asked to be favoured with something strong and hollow, into which I might direct a now semi-exposed point. A pewter eg cup, a poker, and a smoothing iron were presented for n ceptance! and presently several neighbours of my patient dropped in with latch keys of many ages and sizes—one of the latter answered my purpose admirably, and it enabled me to remove from its abnormal position the cause of much anxiety and suffering to my patient. This proved to be a *needle*, with eye and point complete (the latter blunt on account of its thick jet black coat of oxidation), of the kind used for ordinary tailoring purposes.

Neither ooze of serum, blood, or matter, accompanied the withdrawal of the needle, and on the day following its removal my patient resumed active employment, buoyant, and blessing the doctor. But he is quite unaware when or how the needle found its late resting place, and assures me that for some years previous to his recent sufferings he occasionally experienced pain in his right thigh, then in his groin, and subsequently in his abdomen, and feels convinced the needle made its way to the position which it occupied at the time of its removal by me, through other regions of his person, gradually, and from the period of his infancy.

The needle is in my possession, and I have been informed it is not of recent manufacture. The thickened stricture by which it was surrounded, as it lay *in situ*, became absorbed ere many days.

CLINICAL MEMORANDA.

TABES MESENTERICA—INUNCTION.

(Reported by John W. Martin, M.D.M.Ch., Q.U.I.

The following case, illustrating as it does the success to be obtained in suitable cases from the treatment by inunction of the wasting and diarrhœa accompanying the affection known as tabes mesenterica, will, I trust, prove interesting:—

Case. (Notes taken Jan. 28th, 1870).—Thomas Moor, æt. two years, delicate for the past twelve months, troubled with an almost incessant purging, rarely ceasing for any length of time. About five weeks previous to date on which these notes were taken, he suddenly "lost his walk;" from which time the purging became incessant and rapid wasting set in. He complained of a great soreness of the body, any attempt at moving him giving great pain. The abdomen was hard, tender, and swollen. A severe cough caused him to vomit almost everything he eat. The expression of his face was most piteous. During four weeks that he attended at the Dispensary astringents of all kinds failed to give any but the most temporary relief. Nothing but a fatal result seemed awaiting him. Seeing in the Medical Press and Circular for January 22nd, 1870, the suggestion to treat such cases by inunction with olive oil, I thought the opportunity a favourable one for giving the treatment a trial. I ordered the mother to rub the oil, previously warmed, well into the child night and morning, and then to wrap him in flannel and prevent his getting fresh cold. On the 28th, the date on which these notes were made, the following is a comparison of his condition before and after the adoption of the treatment:—

BEFORE.	AFTER.
1. Purging.	1. Almost gone.
2. Cough and vomiting.	2. Losing cough, and vomiting altogether stopped.
3. Soreness of body.	3. None.
4. Wasting and emaciated appearance.	4. Appearance greatly improved.
5. Anorexia.	5. Appetite improved.
6. Unable to walk.	6. Able to walk.

From this time forward improved greatly. Placed him on Cit. ferri. ammon. and cod-liver oil. In the latter part of April had a recurrence of the purging, though nothing like what it had been in January; again, the inunction completely checked it, and he is now doing well.

In the above case inunction answered admirably, but I have met with other cases in which it had no effect whatever. Whether the failure was due to its being improperly or imperfectly carried out, I cannot say, but still, I think,

we must only regard it as one amongst many remedies with which we can do battle with a most serious and painful affection, and with which all engaged in practice are well acquainted. We may well feel thankful if it prove of service in some of the many cases that fall under our notice.

Hospital Reports.

INTRA-ABDOMINAL ABSCESS EVACUATED BY THE "ASPIRATEUR."

By Mr. Morgan, F.R.C.S.I.

Surgeon to Mercers' and the Westmoreland Lock Hospitals.
Professor of Surgical and Descriptive Anatomy, R.C.S.I.

Since the report of this remarkable case in the last number of the Press, the opening made by the trocar tube of the "aspirateur" became established with the surface, and, though not exceeding a crowquill in size, it poured out in the first three days an immense quantity of purulent matter of the same thick, healthy-looking appearance, with considerable fœtor. Many ounces were discharged daily.

The amount is now lessening daily, and the opening is rather closing; the fœtor also is less, and the patient's health has improved so much, that she ventured to get up and walk about during the absence of the nurse.

ARMY HOSPITALS.

Case of Aneurism of the Heart, situated at Apex of the Left Ventricle, bursting into the Pericardium, and causing immediate death.

By Staff-Assistant-Surgeon McNalty, M.D., F.R.C.S.I., Devonport.

Private R. N., æt. 26, a bandsman belonging to the 2nd Battalion Rifle Brigade, of nine years' service, five of which were passed in India, was brought dead to the Military Hospital, Stoke, Devonport, on 21st April, 1868.

History.—His Medical History Sheet shows that he had primary syphilis in 1862, since which period he was admitted into hospital three times for secondary symptoms; he had also been subject to chronic rheumatism.

He was considered a tolerably healthy man, was in the habit of playing the trombone, or some other brass instrument, and was constantly practising. Latterly he had lived pretty freely, but not to the extent of intemperance. On the 16th April, 1868, he felt indisposed, and was excused playing in the band on that day, but did not, however, feel sufficiently ill to seek admission into hospital. On the day preceding the evening of his death, he was subject to much mental emotion. The following account of the circumstances attending his death is furnished by a comrade:—

About 8.20 p.m. on the 21st April, the deceased entered an inn in Devonport, apparently in his usual health. Being offered a glass of ale, he made no reply, but walked over to a table in the room where some men were drinking, and immediately afterwards fell down. He appeared quite insensible, and was taken into the open air, but did not seem to revive; he was then conveyed without delay to the hospital.

There was some delay in making a *post-mortem* examination, owing to the supposition that a coroner's inquest would be held.

Appearances 38 hours after Death.—Body muscular, well nourished, and covered with a considerable amount of fat; scrotum, œdematous; no external marks, with the exception of some old scars, not adherent to the bone, and situated in front of both tibiæ. There was observed to be a want of death-like pallor in the countenance. Rigor mortis moderate.

The circumpallate papillæ of the tongue were somewhat enlarged. The larynx, trachea, and larger bronchi, were free from disease.

On opening the chest, the lungs were found not to collapse as much as usual; they were decidedly emphysematous, and were partially congested; pleuræ, healthy. The pericardium was enormously distended, overlapping and pushing aside the left lung. It was much thickened, especially where it embraces the large vessels at base of heart, and contained, at a rough guess, upwards of 20 ozs. of serum, blood, and loose, soft coagulæ.

The heart, from pressure, appeared twisted on its long axis, and, from maceration in the contents of the pericardium, was rough on its external surface (not unlike an ox's tongue), from disintegration of the superficial muscular fibres. The organ was very large, flabby, softened in texture, and of a dirty buff colour, and presented at apex a collapsed bag-like appendix which proved to be an aneurismal sac, quite empty, and capable of containing about three ounces of fluid. It communicated with the left ventricle alone by an opening three and half inches in circumference, surrounded by a thick smooth zone of the muscular fibres composing the "vortex," converted into fatty tissue. This degeneration had extended to the muscular papillares, as they spring from the walls of the ventricles, and was also very evident along the septum ventriculorum. The sac itself was deeply congested in various spots, and so thin that in some places its lining membrane and the pericardium were in direct opposition. The rupture had taken place at a part situated farthest from the apex of the heart, and was so limited in extent that it was not an easy matter to determine its precise seat, the water introduced for this purpose into the sac percolating very slowly through, and appearing more as a weeping, than otherwise, externally; this depended, perhaps, in a great measure, on the opening being blocked by the lining membrane of the sac.

The anterior curtain of the mitral valve, at its base, had a whitish appearance, as also had the semi-lunar valves of the aorta (particularly the two posterior), causing a loss of transparency, but no appreciable thickening; the right ventricle was dilated; the tricuspid and semi-lunar valves of the pulmonary artery were normal.

All the heart's cavities were empty; the larger vessels leading to right heart gorged with blood. The aortic arch presented white puckered streaks, as if atheromatous degeneration were commencing; the descending aorta, both thoracic and abdominal, and common iliacs were all healthy.

The liver was congested; the spleen about three times its ordinary size, and very friable—it broke down in the hand while being removed; the kidneys were highly congested; the stomach was distended with gas.

The tissues composing the scalp were congested; the partial bones presented, on either side of the sagittal suture and near the posterior extremity of the latter, two depressed spots, darker in colour than the surrounding osseous structure, and probably due to syphilitic poison; the brain substance appeared rather anæmic than otherwise; all the intracranial arteries were free from disease; no arcus senitis present.

A microscopical examination of the rough external surface of the heart showed interlacing muscular fibre, and a slice from the thick zone a granular appearance.

Remarks.—The history of the case explains pretty clearly the *post-mortem* appearances. The occupation of the individual causing force, respiratory efforts led to emphysema of the lungs and dilatation of the right ventricle, and the inordinate exertion, telling on a diseased heart, resulted in aneurism, which took place, as it generally does, in the left ventricle, which, unprovided with either a safety-valve arrangement or a moderator band to limit over-distension, which exist on the right side, has the hardest work to perform. It occurred also at a part where the disease

has made its most rapid strides, and where the walls of the cavity are anatomically weak—at apex, where the superficial fibres curve in. The commencing disease in arch of aorta, and the general tendency to adipose deposit, are to be taken and received as indications of the general malnutrition which existed. The case is remarkable for its comparative rarity. With regard to nomenclature, it would come under the head of true aneurism of the heart—the chronic form, or second variety, described by Rokitansky; it is of peculiar interest to Army medical officers, as the relative frequency of heart-disease among soldiers, as compared with the civil population, is a subject at present under consideration. Although there are no signs by which the disease could have been diagnosed with certainty during life, it is strange that no symptoms were complained of, with the exception of the slight indisposition alluded to.

Professor Aitken, who has very kindly favoured me with a communication with regard to the pathology of the case, is inclined to assign a syphilitic origin to the disease, and the history of the case favours this view; but I would have expected a greater amount of *syphilitic* cachexia to have existed during life, and a "gummatous nodule" to have had a more circumscribed area than the diseased structure had in this case. I may add that an independent examination of the part by an able microscopist showed fatty degeneration of the heart's fibres, and it is very probable that the two agents—syphilis, and morbid nutrition as expressed by fatty degeneration,—both contributed to weaken the heart's walls and cause the aneurism.

Case of Drowning.

Reported by Surgeon-Major Webb, M.B., Winchester.

Hammond's Baths are situated in the meadows near the river at Winchester, a short distance from the town. The soldiers of the 7th Depôt Battalion are marched down to the baths daily in detachments of 150 or 200 men. On the 19th July, the men had only been in the water a short time when a cry was raised that a man was drowning. The man was seen to sink, and great confusion followed. The size of the baths being small, the number of the men great, together with the noise, caused some little delay. The men commenced diving for the body, but unsuccessfully. The drowning man kicked one man, and then shortly afterwards rose to the surface; in doing so, he came in contact with a man diving to rescue him; he encircled his arm arouud this man's neck, and they went down together; the man who was thus dragged down put up his arm for help, it was seen and seized, and he was dragged out in an exhausted state. The men were now urged to continue diving, which they did for two or three minutes; but, owing to the very muddy state of the water, they could not find the body.

The precise time occupied in diving for the body is most important, but very difficult to estimate. The officers and five men, who were most urgent in their endeavours to save the man, agree with me in thinking two or three minutes elapsed. The remarks of the men, "He must be dead long before this," go to show the probability of two or three minutes' submersion.

A man, Private Green, 3rd Rifle Brigade, now volunteered to recover the body. Stripping off his clothes, he most courageously dived, reached the body, but failed to bring it up. He then took breath and dived again; this time he seized the leg, drew the body under water to the bank-side, seized the bank with his other hand, and directly he was seen a rush was made, and both were pulled up the bank.

Being an eye-witness of the whole, the determination, resolution, and courage of Private Green are beyond all praise, and struck me as an act of noble devotion to save a fellow creature.

Unfortunately the men and the body were on the opposite side of the baths to myself. Having called upon the men to rub the body, I ran round the head of the bath and on to the meadows, but found myself and Captain Knox cut off from the drowned man by a large muddy impassable ditch. Returning, we ran round below, and had to jump two large and several small ditches, and a distance of high meadow grass. Then a heavy thorn fence to keep out intruders had to be climbed: with great difficulty I got on the top of the fence, and jumped down amongst the men.

This detail is all-important. The time occupied in going round, jumping ditches, and getting over the high fence, Captain Knox and myself think occupied three minutes.

The work of resuscitation now commenced. There were no signs of life: the body was livid and cold, the face and neck black, eyes all but closed and fixed, jaws rigid and fixed. The Sylvester process was now used—seizing the wrists and elevating the arms high above the head, putting the pectoral muscles well on the stretch, and endeavouring to the utmost to increase the distension of the chest; the arms were then relaxed and, falling on the chest, firm pressure was applied on either side of the chest to expel every particle of air.

During the first two or three distensive motions, a gurgling tracheal râle or rattle was audible, which sound soon extended to both sides of the thorax. It was very distinct, resembling, in every respect, the passage of air through water—a bubbling, gurgling noise.

The resuscitation, as above, went on for the first quarter of an hour with little or no result, as far as external signs went. I endeavoured to imitate ordinary respiration, and to limit the number of artificial respirations per minute, as far as I was able. At the extreme elevation of the arms, when the capacity of the thorax was at its highest point, a few seconds were allowed to elapse before gradually relaxing the chest muscles; firm and steady pressure, to compress the whole of the chest and expel air, followed; then a small interval, and the elevation process recommenced. During the whole of this time, six or eight men were rubbing and drying the body, cleaning the mouth and nose, &c., in a most energetic manner; their flannel shirts were used to form a pillow for the head, which was only slightly raised, and also to rub the body with.

Whilst resuscitating, I gave directions to these men, urging them to save the life of their comrade; and the assiduous flannel friction and hand-rubbing were most praiseworthy.

During the second quarter of an hour (the exact time cannot be given), whilst watching the chest, a spasmodic, short kind of inspiration now and then became observable, at first of a very doubtful character; after some minutes, more clearly developed. It appeared as if the respiratory actions were commencing in short portions. The resuscitation was, however, continued, and these symptoms not depended on.

About the end of the first half-hour, the strength of these respiratory efforts were manifestly improving. During the next quarter of an hour they were so far improved as to induce me to venture to relax the artificial process; but *in an instant* it was evident they were of little strength, and not to be relied on.

About this time the first indication of movement occurred. It was with the greatest pleasure and deepest interest, after watching the body upwards of half an hour, I saw *the right upper eyelid* raised a very little, and only for a second, and in a few minutes afterwards the left upper eyelid moved.

The exertions of the men were now redoubled; every one had hopes; the skin had lost its cold dingy character, the face became clearer and lighter, and then a small temporary movement of both eyeballs followed.

In the next quarter of an hour, the respiratory efforts became stronger; but still very short, convulsive, or spasmodic in character.

At the expiration of an hour, reanimation was fairly established: the face had lost its lividity, the lips were assuming a natûral rosy tint, the jaws were unlocked, the

skin had some warmth; he could be roused by loud talking, but could not speak.

Exhausted by the exertion, I left the Sylvester process, and tried the side-to-side rolling process; he rapidly became worse, and the Sylvester process was resumed by a non-commissioned officer under my instructions.

Even at this time the man's condition was critical. On relaxing the process, to see if nature could carry on respiration, he went back; the head fell, and the eyes became closed.

Brandy having been obtained, with great difficulty he swallowed about a drachm, but it revived him.

Blankets and hot water were at hand, but the extremities were still very cold. The water was very hot, and, not having had a good full inspiration yet, I poured the hot water rapidly over his feet and legs; it had the desired effect; a scream and a fine full inspiration followed.

During the third half-hour he commenced to speak; but the oppression of the breathing, the drowsiness, and the râles in his throat and thorax indicated mischief.

When the circulation was fully established, he took a little more brandy, was wrapped up in blankets, and then carried to barracks.

On his arrival his condition again became alarming: the oppression in his chest, the difficulty of breathing, and the lividity of his hands and face, again appeared. A warm bath, stimulants, and mustard sinapisms rallied him; he became warm and perspired freely. The respiration, however, did not improve, and the pulse was rapid and feeble.

The obstructions to the pulmonary circulation were very evident; the face was congested, and the nails and fingers livid.

During the next twelve hours (the accident occurred at four in the afternoon) he dozed a little, and answered questions better. The improvement, however, was of short duration: the symptoms now were aggravated, the heart laboured, the pulse was galloping and feeble, the râles increasing, the pulmonary congestion urgent, and he died twenty-six hours after his accident.

The *post-mortem* revealed great pulmonary congestion, dirty-looking water in the larger bronchi, and a mottled emphysematous appearance externally of the lungs.

The larynx and adjoining parts were congested and swollen; effusion at the base of brain, and a remarkable gorged distended state of the lateral sinuses, also presented.

The chief interest in this case is the *time* this man was submerged, and it is necessary to speak with due caution and careful consideration. The actual submersion, Captain Knox, in his Report to the Royal Humane Society, has stated from *three* to *five* minutes—in my Report to the Society I gave five minutes, or about five minutes; but the evidence of the five men who were near the drowning man gives five minutes as the probable time, and even Captain Knox informed me it might have been five minutes. However, taking four minutes, the submersion is one of the longest on record in which resuscitation has followed.

Transactions of Societies.

MEDICO-PSYCHOLOGICAL ASSOCIATION.

The annual general meeting was held at the Royal College of Physicians on Tuesday, August 2nd.

Dr. Boyd, President, in the chair.

A letter was read from Dr. Lockhart Robertson, resigning his office as one of the editors of the Journal; and a resolution was passed acknowledging the services which Dr. Robertson had rendered to the association, and congratulating him on his appointment as Chancery Visitor in Lunacy.

A resolution proposed in favour of the amalgamation with the Royal Academy of Medicine was rejected in favour of an amendment declaring such amalgamation undesirable.

Dr. Maudsley was elected president for the ensuing year; Secretary, Dr. Harrington Tuke; Editors of the Journal, Dr. Maudsley and Dr. Sibbald; Treasurer, Dr. Paul.

Sir James Alderson, Dr. Frederick Farre, and Dr. Lockhart Robertson were elected honorary members.

Dr. Boyd delivered an address advocating better provision for the early admission of acute pauper cases of insanity into county asylums, by providing for the proper care and treatment elsewhere of chronic and harmless cases. A discussion followed, the general opinion being that the present county asylums were too large and ill-fitted for the best treatment of acute cases of insanity. A strong opinion was expressed by some members that insanity was not increasing out of proportion to the increasing population.

Dr. Davey read a paper on *Felo-de-se*, advocating the view that suicide is always the result of cerebro-mental disorder. A discussion followed, in which several members protested against the opinion that suicide was, in all cases, an indication of mental disorder, maintaining that perfectly sane persons might commit suicide.

On the motion of Dr. Arlidge, a committee was appointed to examine the lunacy laws of the Continental States and of America, with a view to the suggestion of improvement in the Lunacy Acts of this country.

The members and their friends dined together in the evening at Willis's Rooms.

Literature.

HOLMES'S SYSTEM OF SURGERY.*

The third volume of our modern surgical cyclopædia comprises diseases of the eye and ear, of the organs of circulation, the muscles and the bones. It it is almost superfluous to say that the publishers have brought it out with the same care as its predecessors, and that the authors have revised their respective articles, so as to bring them down to the present date. This second edition is in fact an improved one—not a mere reprint—and the conjoint labours of so many first-class surgical writers, ably represent the present state of British surgery.

The first treatise is by Mr. Dixon, and we now have three original lithographic plates showing ophthalmoscopic views of the fundus of the eye. There being two views on each plate, there are thus six beautifully coloured illustrations. The letter-press of Mr. Dixon requires no recommendation. What he teaches us is sure to be accepted. There must be thousands of practitioners who desire to read up ophthalmic practice, and hardly know what book to buy. Let them get Holmes's system, and they will find in this volume all they want in less than 300 pages.

A similar remark might be made as to the next article in which Mr. Hinton gives an account of diseases of the ear, which every general practitioner may read with advantage. Since the death of Toynbee there is no one who could pretend to rank as the equal of Mr. Hinton in this branch of our art, and Guy's Hospital may well rejoice in having him as aural surgeon. As a *littérateur* of note, too, we expect to find his work not merely full of learning and practical remarks, but set before us with so much felicity of style as to make it attractive, and we are not disappointed. Mr. Hinton speaks with authority, and his dicta will be so universally accepted that we have no criticism to offer.

Mr. Callender's article "On Diseases of the Veins" has not been materially altered in this edition; nor has Mr. C. H. Moore's "On the Arteries and the Absorbents."

The learned editor gives a separate treatise "On Aneurisms," and this important subject could not have fallen into better hands, and we have many most instructive cases both in a tabular form and in a more extended form. This essay could only have been the production of an accomplished surgeon and clinical teacher.

* A System of Surgery. Edited by T. Holmes, M.A., Surgeon to St. George's Hospital, &c. 2nd edition, in 5 vols. Vol. 3. London: Longmans and Co. 1870.

Dr. Lockhart Clarke edits Mr. Tatum's article "On the Muscular System." His revision guarantees the most recent discoveries not being overlooked.

Dr. Little, the father of English orthopædy, is the author of the article on this branch of Surgery. Careful revision and additional woodcuts enhance the value of this edition, and show that Dr. Little thoroughly knows the wants of the general surgeon as to deformities.

The last article "On the Bones" is by Mr. Holmes, to whom we offer our cordial thanks, not only for the articles in the volume under notice, but for the project of his "System of Surgery," the energy and skill with which he carried it out, and for the improvements in the three volumes of the second edition now issued, and which are a sort of pledge for the remaining two, to which we look forward with unusual interest.

EDINBURGH OBSTETRICS.*

The Northern capital claims high rank in Obstetrics, and we need not, therefore, be surprised that it has been decided to give the Transactions of its Society a permanent form. We have here the first volume before us, and are glad to find that though its value is fully equal to that of its London sister, the bulk of the book is considerably less. The papers have appeared as they were read in the *Monthly Journal of Edinburgh*, and have merely been corrected by their respective authors. In the discussions on the papers the Publication Committee determined to reprint only such portions as were relevant to the subject matter of the respective papers; in fact, we have only here recorded the remarks that may be thought worth reading. The papers contained in this volume are classified in the table of contents under six heads, according as they relate to (1) pregnancy; (2) instruments and instrumental cases; (3) obstetric and medical agents; (4) diseases of women; (5) children and their diseases; (6) obstetrical, sanitary science and hygiene.

This classification is not adhered to in the work itself, but the Transactions are reported according to date. Thus, we have a continuous history of the Session of the Society, while the contents, being classified, render reference easy.

There yet remains an Appendix. This deserves separate mention, as it is in itself a most valuable contribution to obstetric bibliography. It is no less than a complete catalogue of all the papers that have been read before the Edinburgh Obstetrical Society, from its commencement, with their dates and the authors' names. It is arranged alphabetically, and by its aid any one may, in a few minutes, ascertain all the contributions to the Society on any subject he may select, and, the dates being added, he may know where to look for the reports in the *Edinburgh Journal*. This catalogue has been compiled by one of the Secretaries, Dr. R. P. Ritchie, who for such a service deserves the thanks, not only of the Society, and of the authors, whose ideas are thus made so easy to ascertain, but of all who take special interest in the progress of obstetrical literature.

It is almost impossible to exaggerate the value of such a compilation as this. The only thing that could supersede it would be a brief abstract of all the Proceedings of the Society by an impartial hand, and making a volume of about the size of the one before us. Few would dare to attempt that, though, perhaps, after this specimen of his patient work, it might be supposed Dr. Ritchie would not shrink even from that. In such a case the Society would do national service by issuing the work.

CURRENT LITERATURE.

The second part of Mr. Spencer Watson's work on "Abscess and Tumours of the Orbit" has been published by Mr. H. K. Lewis. It is a worthy sequel of Part I., previously noticed in our columns, and is illustrated by two fine plates, besides wood-engravings.

Dr. T. Fox has issued in a separate form his lectures on "Eczema" at the Medical Society of London, and which were published at the time in one of our contemporaries.

Dr. Corfield sends us a *resumé* of the "History of Hygiene," being the lecture introductory to his course on the subject, also reprinted from a contemporary.

Dr. Macnamara has printed a popular letter on the subject of the "Medical Bills," in which he suggests that rejected students might be prevented from passing at other boards by their certificates being retained by the rejecting board for a period of six months.

Dr. Dobell has brought out a fourth edition of his "Diet and Regimen in Sickness and Health." (Lewis.) It is considerably enlarged, and is stated to have been re-written.

The Half-yearly Abstracts which we should have announced last month, are, as usual, the cream of the periodicals for the past half-year, and their editors seem to fulfil their respective tasks with great discrimination.

The second edition is before us of "Deformities of the Mouth," by James Oakley Coles. (Churchills.) By the aid of some excellent plates Mr. Coles makes the subject of mechanically remedying cleft palate and other deformities plain to medical men as well as to dentists. His conclusions are based on fifty-eight cases, and deserve attention.

SCOTLAND.

UNIVERSITY OF EDINBURGH.

On Monday, the 1st, the ceremony in connection with the conferring of degrees took place in the Assembly Hall, in presence of a numerous attendance of ladies and gentlemen. The Chancellor (the Right Hon. the Lord Justice General) presided. The Dean of the Faculty of Law presented to the Chancellor, Dr. Acland, and Professor Max Müller, of the University of Oxford, upon whom were conferred the honorary degree of Doctor of Laws. The Dean of the Faculty of Medicine presented the following gentlemen, who had been judged worthy to receive degrees in medicine :—

Degree of Doctor of Medicine.—(Three stars indicate those who have obtained gold medals for their dissertations; two stars, those deemed worthy of competing for the dissertation prize; and one star, those commended for their dissertation.)—*Candidates who received the Degree under the New Statutes* :—Peter Buchan, Scotland; *James Spottiswoode Cameron, Scotland; William Hodgson Carruthers, England; ***Richard Caton, England; William Craig, Scotland; *Alexander Crombie; James Dunsmure, Scotland; ***David Ferrier, Scotland; *William Alexander Finlay, Scotland; *James Forrest, Scotland; Thomas Silvester Gell, England; Charles Bailey, Glenfield, England; Robert Bruce Low, Scotland; *Richard Lowther, England; Robert Lucas, Scotland; *William Paton Mackay, Scotland; *Harrison Mitchell, England; *Francis Walter Moinet, Scotland; Philip Henry Mules, England; Williams Nicholson, England; Walter Hugh Paterson, England; **John Wilson Paton, Scotland; Michael Welldon Rice, England; **Henry Sydney, England; Robert Shand Turner, Scotland; Yldefonzo Victor Watlington, Puerto Rico; Alexander Christy Wilson, Scotland; *Peter Alexander Young, Australia. *Candidates who received the Degree under the Old Statutes* :—William Chapman Grigg, England; *Edwin Hinchcliff, England (first-class honours); *Charles Julian Jackson, England; James Alexander Menzies, Scotland.

Degrees of Bachelor of Medicine and Master in Surgery.—Walter Duret Aubin, Jersey; John Bishop, England; Robert Blair, Scotland; Archibald Breloch (M.A. Glasg., Dr. Sc. Edin.), Scotland; James Pitcairn Bookless, Scotland; James Brassey Brierly, England; William Brown (M.A. Aberd.), Scotland; Alexander Chambers, Scotland; William Copeland, England; John Archibald Cowan, Scotland (second-class honours); James Denholm, Scotland; Edward Harriman Dickenson (B.A., Oxon.), England; George Tait Dickson, Scotland; Walter Dixon, Australia; Richard Wright Dodds, Berwick-on-Tweed; James Williamson Edmond, Bengal (second-class honours); John Nicholson Fleming, England;

* Transactions of the Edinburgh Obstetrical Society. Session, 1868-9. Edinburgh: Malachlan and Stewart. 1870.

Edward Flint, England; Arthur Edward Wellington Fox, England; John Fraser, Scotland (first-class honours); George Western Gipps, England; Alexander Gordon, Scotland; John Gibson Gordon, Madeira; Peter Macpherson Grant, Scotland; John Brodie Henderson, Scotland; William Balme Hepworth, England; Henry Walter Hill, India; Thomas Irvine, England; Walter Robert Spence Jefferiss, Scotland; William Gregory Keith, Ceylon; William John Kennedy, Scotland (second-class honours); Alexander Macdougall, Scotland (second-class honours); Duncan M'Gregor (M.A. Aberd.), Scotland; Robert M'Kerchar, Scotland; Hugh Marriner, England; Henry Charrington Martin, England; Thomas Dickenson Nicholson, England; John Nivison, Scotland; John Cunningham North, Wales; David Page, Scotland (first-class honours); Arthur Perigal, Scotland, received the degrees of M.B. and C.M. on November 19, 1869; James Reoch (M.A. Edin.), Scotland; James Turnbull Richardson, England; John Lloyd Roberts, Wales; Thomas Rutherford, Scotland; Henry Salt, England; Robert Spence, Shetland (first-class honours); William Thomas Wood, Scotland; Thomas Allan Wotherspoon, Scotland; William Wylie, Scotland.

Degree of Bachelor of Medicine.—John Drysdale, Scotland; Henry Ambrose Lediard, England; Roderick Fraser M'Kenzie, Scotland.

Degree of Master in Surgery.—John Brown Buist, Scotland, M.B., 1867.

The Ettles Prize of £40 to the most distinguished student for the year has been awarded to David Page.

Professor Laycock then delivered an address, selecting as his subject, "Education in Relation to Public Health and the Public Welfare." Immediately after the graduation ceremonial, the Chancellor, accompanied by the Senatus Academicus, Lord Neaves, Dr. Acland, Dr. Max Müller, Dr. Lyon Playfair, M.P., Mr. Gordon, Q.C., M.P., &c., proceeded to the University buildings, when the statue of the late Principal, Sir David Brewster, was inaugurated. Lord Neaves, on behalf of the subscribers, addressing the Chancellor of the University, formally delivered over to the University the "Brewster Memorial" statue. The statue was then unveiled, the band of the University Rifle Corps playing the University air, "*Alma Mater.*" The Chancellor in suitable terms acknowledged the gift which, through Lord Neaves, had been presented to the University.

Professor Maclagan said he had to discharge a duty, without which the proceedings of the day would not be complete. On the part of the Committee of Subscribers, he had to thank Mr. Brodie, the artist, for the prompt way in which he fulfilled the commission which was entrusted to him; and, on the part of those who were the recipients of the statue, he had to express to that gentleman their thankfulness for so great an ornament to the College quadrangle—for a representation of one who was so highly esteemed, of whom every Scotchman was proud as a countryman, and to whom those, more particularly, who had the honour of being his colleagues, looked back with so much reverence.

The statue, which is placed upon a pedestal, measures seven and a half feet in height, and occupies the centre arch on the west side of the College quadrangle. It is an admirable likeness of Sir David Brewster, and, as a work of art, the statue is in every way worthy of Mr. Brodie's high reputation.

Professor Allman, on closing the class of Natural History for the summer session, was presented by his students with a handsome time-piece, and a congratulatory address on his restored health.

We are glad to learn that the result of the meeting held in London a short time ago with regard to the present constitution of the Court of Curators in the University of Edinburgh has been unanimously to demand a change in the constitution of that Court. Reports from all parts of the country have been received by Dr. John Murray, the hon. secretary, urging him to carry out the resolutions of the meeting.

GLASGOW UNIVERSITY.

The Senatus Academicus, and other officials connected with the University, dined together in the Fore Hall on the 29th July to commemorate the occasion of their taking leave of the old buildings.

In a powerful article on the recent capping ceremony, in the Edinburgh University, the *Evening Courant* urges the importance of transferring botany and some other subjects to the preliminary training of students, so as to reserve all their strength for their strictly medical studies during their brief curriculum. The same article shows that the modern rise of State Medicine is "but a resuscitation of the doctrine inculcated by the Father of Medicine himself" in the following manner:—"Counsel the young physician to observe the situation of places, the difference of the air, the waters which are drunk, and the eatables which are the principal food of the inhabitants; in a word, all the causes that may occasion disorder in the animal economy." Upon this happy quotation the *Courant* comments with its usual interest in medical affairs as follows:—"We might go on to paraphrase the inculcation of the 'divine man of Cos' to still ampler issues, affecting the community and, through the community, the individual. But we have said enough to vindicate for the cause of State Medicine an august antiquity which ought to add fresh stimulus to its modern revival." We wish more of our London papers exhibited that appreciation of professional matters that characterises our valued Edinburgh contemporary.

SPECIAL CORRESPONDENCE.

M. CHARCOT'S CLINIQUE.

[FROM OUR OWN CORRESPONDENT.]

Paris, August 1870.

I sent you, a short time ago, some notes of the lectures which have recently been delivered at Hospice de la Salpêtrière, by an esteemed physician, M. Charcot, on certain disorders of nutrition, resulting on lesions of the nerves.

M. Charcot, in his second lecture, observed that the experiments of Erb Ziemssen and Weiss have recently thrown great light on this subject by certain experiments on rabbits, whose nerves were wounded, and in which daily observations were made as to the modifications of electric contractility, which ensued in the nerves and the muscles, under the influence of continuous currents and of faradisation. If the sciatic nerve of a rabbit be wounded severely, we observe almost at once a loss of electric excitability, whether recourse is had to faradisation, or to galvanisation, and, whilst it returns slowly at the centre end, it is rapid at the peripheric end. If the lesion be slight, the electric excitability returns quickly in the central end, and never completely fails to exist at the peripheric end. With regard to the muscles, faradisation shows from the very first day a diminution, and, a few days further on, a loss of contractility. Galvanisation denotes, during the whole of the time which corresponds to the depression of faradisation, an exaltation which, in its turn disappears, when faradisation becomes powerful again.

These facts are relative to conditions comparable with those which pathology presents us with. The above-mentioned observers operated as follows:—Almost always they applied upon the nerve a ligature more or less tightly drawn; or, again, they produced by means of forceps, a more or less marked crushing of the nerve. Their experiments also show that, if a nerve is cut through or excised

for a few lines, then the electric contractility diminishes in a progressive, although very slow, manner. It requires two or three months for it to disappear, and not only five to fourteen days as when it was crushed. In this case, too, we no longer notice that opposition between faradisation and galvanisation, which was remarked when the nerve was crushed, and exists in most pathological cases. The two modes of exploration produce exactly parallel results; the faradic contractility and the galvanic contractility became weakened together, and are together reproduced in their first intensity when the nerve is restored.

With regard to the disturbances of nutrition, which ensue after lesions of the spinal cord, the skin, the joints, the bones, and the viscera themselves may, generally speaking, become the seat of derangements of nutrition, consecutive to lesions of the spinal cord and of the brain. There are some special affections which very rapidly cause all modes of muscular alteration, whether functional or organic, which lesions of the nerves have made us acquainted with. On the other hand, there are some in which electric contractility and the nutrition of the muscle preserve them in a condition of perfect integrity, during a considerable space of time, months, or even years. The muscle, in the latter case, only becomes altered after a long time, under the influence of prolonged rest. In the first class, we range the spinal diseases which do not directly modify the structure of the muscle. These are, tumours, Pott's disease, partial myelitis. In these cases we have to do with very circumscribed lesions of the spinal cord, and only affecting a very limited portion of the grey substance. Next come even very extensive lesions of the white columns, provided that the grey substance be not attacked to a certain extent. I will cite, as specimens of the last class, all the riband-like scleroses of the posterior or lateral columns, or the sclerosis which occurs in disseminated plates, and even inflammatory softening of the cord. The second group comprehends those affections of the cord which may be followed by grave and almost immediate modification of electric contractility and by rapid atrophy of muscles. In cases of lesions which are confined to a focus, or, being diffused, affect a great extent of the grey substance of the cord, as in spinal apoplexy, we may see very rapidly occur diminution or even loss of the electric contractility in the muscles of the paralysed limbs. This has been observed in fourteen days. As this is a disease which in general proves rapidly mortal, we have frequently occasion to remark as its consequence either atrophy or degeneration of muscles.

Central myelitis sometimes attacks both the white and the grey matter of the cord, but it always predominates in the latter. This lesion has for one of its symptoms the diminution or prompt abolition of electric contractility. In a case of this kind an observer, Maunkopf, saw the contractility modified as soon as the seventh day. When the patients survive, it is easy to follow the progress of the other correlative phenomena; atrophy is rapid and the muscles soon are degenerated. According to Engelken and Maunkopf, the muscular lesions consist in a proliferation of the connective tissue. The nerves have always been found healthy. Fractures of the vertebral column sometimes are followed by myelitis. It is not astonishing that, in such cases, there is noticed sometimes a prompt diminution of the electric contractility.

The second category is composed of affections arising from more delicate lesions in which are exclusively affected at least at the beginning certain elements of the cord, *e.g.*, some of the great nerve-cells of the anterior cornea. These are usually irritative lesions. In such cases the white matter of the cord is ordinarily intact. The type of affections of this nature is infantile spinal palsy. In this disease we may remark setting out from the fourth day, a diminution, and shortly after a complete loss, of the faradic contractility in certain muscles. Soon, also, there is observed muscular atrophy which progresses rapidly. Some histological observations which require verification announce, in such-like cases, the simple atrophy of the primitive fasciculi with persistence of striatum. It is not known whether prolification exists; but, at any rate, the loading with fat observed sometimes in very old cases, is probably consecutive. Around this type we may be permitted to group:—1. Spinal palsy; 2. General spinal palsy—a disease recently described by Duchesne. Its evolution is slower than that of the described diseases, but it furnishes, as far as the muscles are concerned, analogous results. Is now the law of Brown-Séquard applicable to these facts? With respect to the first group, there is no contradiction. The riband-like scleroses which do not produce rapid disturbances in nutrition, are, it is true, irritative lesions, but they affect the white columns. Now we must consider the spinal cord not as we do a great nerve; the cord, we must not forget, is also a centre. The white cords are never the direct continuation of the nerve trunks, they are commissions established between the cells. Besides, we know that the white columns are gifted with properties very different from those of the nerves which issue from them.

With regard to the diseases which compose the second group, it is indispensable to remind ourselves that the lesions attack here always principally and exclusively the grey matter. In the substance are found some elements, true orgasis, which appear to be in immediate communication with the nervous filaments, composing the anterior spinal roots. I refer to the large nerve-cells of the anterior cornea. Well, the lesions of these cells, when of an irritative nature, determine—not to mention anything but the muscles—effects analogous to irritation of the nerves.

Cornell University.

Medical teaching in the United States seems to be in a very fine condition, if we may judge from the following extract from one of the French journals, the *Mouvement Médicale*:—"In the State of New York, at Ithaca, they are establishing a university founded by a man who commenced as a workman, and began by placing telegraphic posts. Mr. Cornell who has become enormously rich, has founded a university. This is seen sometimes in America, where people sometimes take it into their head to do such things. Mr. Peabody gave six millions of francs to found one at Maryland. Mr. Cornell has just given five millions to found one at Ithaca. But in this university, where all the pupils are on a perfect equality, where law and medicine are taught, there have been reserved three hours a-day for those men who wish to work at manual occupations. There are workshops where they carry on all the work that requires to be done for the university, such as carpentry, locksmith's work, &c. Any one may be a student during the daytime and carry on a trade for three hours. They can then gain from 20 to 25 francs a week, just enough to keep them. This gives us an example which astonishes us, but which is not at all surprising in America, in the respect for manual labour by intellectual workers." France and England have something yet to learn from the United States, besides large and deadly systems of warfare, which I think we might do without.

Army Hospitals.—During the last week a Commission has been sitting at the War Office upon the very important question of the administration of our Army Hospitals. The object of Mr. Cardwell, as submitted to the Commission, is to modify the action taken upon Lord Herbert's Commission of 1858, so as to throw upon the surgeons a greater co-operation between the Control and Medical Departments than exists at present. This, doubtless, in the event of war, will prevent many of the calamities which attended our Army in the Crimea.

The Director-General of the Army Medical Department having called attention to the desirability of sending experienced military surgeons to the head-quarters of the French and Prussian Armies, for the purpose of studying and reporting upon the effects of the more recent inventions of modern warfare, and the most approved methods of transporting the sick and wounded, the Secretary of State for War promised to endeavour to carry the suggestion into effect.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 10, 1870.

THE CHANCE OF THE CORPORATIONS.

Now is the day of grace of the Medical authorities—both Corporations and Universities. They have a good six months before them. Will they use it? We cannot forget that several of them have, time after time, announced their readiness to combine in the manner contemplated by the Act of 1858, and to a considerable extent carried out in Scotland. Calling to mind that the late Bill was framed on the principle of *compulsory* amalgamation, and that many bodies have expressed their wish for *voluntary* amalgamation, we cannot be blind to the probable effect on the Government should the latter plan be at once adopted. Suppose, for example, the Scotch bodies, having gone so far, should take another step in the same direction, and establish a conjoint board similar to that contemplated by the Bill. Would not that be taking such reform out of the hands of the Government, and thus make Scotland indifferent to the Medical legislation that the Privy Council is likely once more to propose? The Act of 1858 gives power to "any two *or more* of the Colleges and bodies in the United Kingdom" to unite, in the manner that the Edinburgh College of Physicians has united with its sister College and with the Glasgow Faculty. Now, what is to hinder these three bodies combining altogether instead of partially? and what, again, is to prevent the Scottish Universities from becoming parties to such an arrangement? Would money alone hinder this? Surely not. Let the bodies unite, and they could give such full authority to practise with the lowest diploma of two of the bodies, that a good round fee ought not to be objected to. Then each could offer its higher diploma on such terms as it pleased.

Further, take the case of Ireland. The principle of voluntary amalgamation has found great favour with most of the bodies. Let them carry it out, and the minority would now be glad to come in before the next Bill is brought forward. The only difficulty is a monetary one. This is proved by the fact that the Royal College of Surgeons in Ireland has twice made overtures to its sister College, which have only been refused on pecuniary grounds. The fee for the diploma of the Royal College of Surgeons in Ireland is £25, that of the College of Physicians £15. The Surgeons propose to charge £30 for the joint diploma, and to make a rateable division, each body reducing in proportion to existing fees. The College of Physicians refused to meet this liberal offer in the same spirit, and must, therefore, accept the blame of the failure of this project. It is not to be forgotten that the surgical body has a museum to maintain, and has educated more than double the number of its sister body. The College of Surgeons in Ireland has always been in the front rank, and in this instance again has shown itself the best friend of the Profession in the kingdom.

It might be well to unite and make the joint fee £35 in Ireland, *i.e.*, each body take what it does now. Still the College of Physicians ought to make some sacrifice, as it would thereby secure all the students instead of a part.

Would it pay the Apothecaries' fees for those who required the Company's licence, or allow the amount to be deducted by all who had paid them? The Apothecaries in no way concern the surgical Corporation.

But we have been told that our English bodies have nearly perfected a plan. Let them only move a little faster, and they may by next Session be in full working order. It is said the two Royal Colleges are quite agreed, but the Apothecaries' Society holds out for some better terms. Would it not be worth while to bear in mind that the Society has a great legal status in England, and has, moreover, done much to elevate the Profession, and, therefore, to yield a little to it in recognition of its services and legal position? Suppose, for instance, the two Colleges and the Society agree each to elect a certain number of examiners for a conjoint board, and that all who passed such a joint board should have the license of the Company, and the lowest diploma of the Colleges conferred upon them at the same time. What stands in the way? Only the everlasting question of fees. The Apothecaries' fee is only five guineas; the College of Physicians', fifteen guineas; the College of Surgeons', twenty guineas. If no reduction were made, this only amounts to forty guineas—a sum which, considering it would give all that could be required, we do not think exorbitant. Other countries exact quite as much, and as much is really paid by many under the present system. If it is really found excessive, some mode of reduction could be arranged. The College of Surgeons could afford, under an arrangement like that, to reduce to, perhaps, fifteen guineas, and the College of Physicians, as it would at once secure so great an increase in the number of candidates, could still more easily afford it. The Surgical College could make up for any loss by raising the fee for the Fellowship, and making it a little more accessible by abolishing a few useless regulations that prevent some aspirants from attaining it. As the College of Physicians, too, is supplanting the Company, it is but fair it should allow at least that amount to be deducted from its fee.

Thus, for thirty guineas the English student would have the most complete diploma that has yet been given. The only thing required is for each body to refuse to give its lowest diploma separately. But the Universities? True, such an arrangement would not compel them to join; but there is nothing to fear from the action of the English Universities. As to the London, none of her graduates would wish to shirk the joint examination. Oxford and Cambridge men are now practically obliged to take one

or more Corporation diplomas, and they would, under the new plan, of course take the joint one—mostly before graduating. The greatest success to such a scheme would be for the Universities to agree to admit no one to their lowest degree unless he had the joint diploma, or, in return for some concession as to appointing also examiners, to give the lowest degree concurrently with the Corporation diplomas to their own students respectively, on payment of the fee and fulfilling other requirements.

The above is but an outline of a scheme which might work easily. We by no means offer it as perfect, nor do we assert that it is better for it to be accomplished than for a radical reform of our whole system to be effected by Parliament. What we do say is, that it is within the powers of the bodies concerned to carry it out immediately; and their doing so would not only forestall the Privy Council, but probably preserve them for a considerable time from the control of that body; and we have reason to think that the Government would be glad of such an excuse for postponing any interference with corporate vested rights. But it must be done at once. We end as we began—*Now* is the day of grace of the Medical authorities.

THE LUNACY BLUE BOOK.

In the whole of England and Wales there were on the 1st January, 1870, a total number of lunatics, idiots, and persons of unsound mind amounting to 54,713. The number of pauper lunatics seems to be largely on the increase of late years; thus, in 1859, these amounted to 31,782, and, in 1870, to 48,325. The 54,713 insane were thus divided:—there were 27,980 in county and borough asylums; 2,369 in registered hospitals; 4,904 in licensed houses; 198 in naval and military hospitals; 462 in criminal asylums; 356 were private single patients. There were also 11,358 lunatics in workhouses, and 7,086 out-door pauper lunatics.

In page 18 of this interesting but sad report,* we find that in Middlesex the Secretary of State has again called the attention of the county magistrates to the want of accommodation in the county for pauper lunatics. At a visit to the Hanwell Asylum in August last year, the Commissioners found that in the interval since their preceding inspection there had been a total number of 927 applications for admission, all but 100 representing separate cases, out of which only 301 ultimately had the benefit of treatment in the asylum. At Colney Hatch, also, during ten months 329 patients were refused admission. At both asylums many of these applications were repeated four or five times before the patient could be received; and, in very urgent cases, the parish authorities had no alternative but to seek accommodation in distant asylums, at a cost for maintenance so greatly in excess of the county asylum, that it can excite no surprise to find that the unfortunate lunatic often remained for considerable periods in most unsuitable workhouse wards, deprived of all curative treatment, and daily losing the chance of ultimate recovery. Although the Commissioners are strongly opposed to any further enlargement of the Middlesex Asylums, they reluctantly consented to recommend increased accommodation for insane patients at Hanwell.

Several cases of violence being used by hospital attendants are still recorded, and once a lunatic seems to have been scalded so as to cause death. The importance of making *post-mortem* examinations, wherever practicable, of the bodies of patients dying in asylums is inculcated strongly in the Report. At Hanwell the practice is to make a *post-mortem* examination in every case without asking the permission of the relatives, although any express wish on their part against an examination is invariably attended to. Out of 76 deaths during the past year in the male division, autopsies were made in 62, and in the female division in every case. From the 1st June, 1864, to the 11th February, 1869, Dr. Lindsay states that 512 female patients have died, and that in all but ten cases *post-mortem* examinations were made (only four of these exceptions being the result of opposition on the part of the friends), and that in no instance have complaints arisen upon the subject. In the West Riding Asylum the practice is much the same, and out of 175 deaths examinations were made in 165 cases. In the Leicestershire and Rutland Asylums, where examinations are usual as a matter of course in every case of death, the consent of the friends is not sought. To ask for permission would, in Mr. Buck's opinion, result in a refusal in nine cases out of ten. All this evidence is extremely important at present. In the printed form for the admission of patients into St. Luke's Hospital the following paragraph occurs:—

"It being very important in the treatment of the insane generally, and conducive to the recovery of those afflicted with that distressing malady, that the physical condition of the brain, as well as the cause of the disorder, should be ascertained in cases of death, the Committee have directed that, should a patient die while in the hospital, the medical officer of the establishment be authorised to examine the body, unless an objection shall have been made in writing to the Secretary previous to the decease of such patient."

Liverpool is a city full of the miseries engendered by mere commercial occupations: we are, then, not surprised to find that the report of a visit to the Liverpool Hospital by the Commissioners is not a favourable one. "With few exceptions, the personal character of the patients was found to be very indifferent; and, indeed, the reason alleged why the females in the lower ward were never on any occasion taken beyond the airing court was, that they had no clothes fit to be seen in. The corresponding class of men were stated to be taken out as little as the women, and both were said to be rarely visited by any friends having any interest in them. The state of the furniture was discreditable in the extreme, and there was a general absence of tidiness throughout."

With regard to St. Luke's Hospital, it seems that in their last report the Commissioners expressed a hope that the governors would forthwith place the hospital under the medical superintendent, subject only to their own control; and, in their reply, it was stated that this was strongly objected to by the house committee. The Commissioners, in reply, again stated that they felt it would be almost needless to repeat arguments so obvious, and so often expressed, in favour of giving, in all asylums and institutions for the insane, the sole and paramount authority and responsibility to the resident medical officer; and they refer to the very unsatisfactory condition in which St. Luke's Hospital had been found at the last visit, as well as on many previous occasions, and to the painful disputes which

* Twenty-fourth Report of the Commissioners on Lunacy to the Lord Chancellor, ordered by the House of Commons to be printed 7th July, 1870. Pp. 277. Blue Book.

had arisen among its officers, in proof of the correctness of their views. No further correspondence ensued; but the stupid governors seem to continue to act as before. Such imbecility is very painful, indeed.

Regarding the system of registering the facts of insanity at present pursued in the county and borough asylums in England and Wales, it seems that the tables suggested by the Medico-Psychological Association, and recommended for that purpose in the Report for 1868, are now in use in thirty-six asylums. With regard to hospital attendants on the insane, in 1851 the Commissioners took occasion to point out that, for satisfactory performance of the duties, it was essential that there should be, not simply the ordinary qualifications of sobriety, honesty, activity, and general intelligence, but that equally indispensable were a fair education in reading and writing, good temper, patience, firmness, habits of self-control; in regard to the more helpless patients, a certain aptitude for learning and directing them in the way of employment or amusement; all which were not to be obtained except in persons of a higher grade than those ordinarily chosen, entitled to better remuneration at the outset; and to whom progressive advances in payment, as well as other privileges conditional on good conduct and length of service, might be ensured as would serve to attract permanently to the duties men really fitted to discharge them. It appears that no great attention has been paid to these excellent recommendations of the Commissioners, so that it can hardly be a matter of surprise that the continually increasing number of inmates in the larger asylums should be accompanied by a more and more frequent recurrence of such terrible incidents as have recently attracted the attention of the public to lunatic asylums. The Commissioners find it difficult to get juries to convict on the evidence of those lunatics who, of course, can alone be supposed to be disinterested witnesses in cases of violence in lunatic asylums. And they complain of persistent neglect in many cases, on the part of proprietors and superintendents, of the precautions established at the office in London against a re-employment in such duties of persons already guilty of misconduct in connection with them. Such are a few fragments from this sad record of human misery, the Blue Book of the Lunacy Board. There is much in the volume which will repay the perusal by all interested in general disease, and especially in social questions.

Notes on Current Topics.

Spermatic Disease.

It will be in the recollection of our readers that a few weeks ago, in an editorial article, we opened up the subject of spermatorrhœa; that we commented upon the absurdity of our brethren ignoring, so to speak, a most important functional disorder, and that we suggested that the only means of defeating quackery and benefiting our patients was to freely discuss the malady in its various forms, to dispense with delicacy in dealing with it, and to attack the malady as we do syphilis and other kindred though, perhaps, less important diseases of the generative system. We observe one of our contemporaries—the *Lancet*—acts upon our suggestion and avails itself of the practical work done by a few members of the Profession; but the editor of that journal, in teaching the treatment of spermatic disease, makes some sad blunders, which, if followed—but there is no member of the Profession foolish enough, it is hoped, to follow such an advice—would eventually lead to irreparable mischief. Our attention has been directed to the point by a practical surgeon well versed in the treatment of spermatorrhœa. In writing of cases wherein there is a libidinous direction of mind, almost akin to insanity, we are informed by the editor of the *Lancet*, in metaphor worthy of his rapidly waning journal, where counsel or warning is thrown off by such patients as water off a duck's back, that the physiological remedy of *regular intercourse* is the only one available. If the writer of the article knew anything practically of the subject he was writing upon, in common with a second years' medical student, he would know such a remedy would surely produce *Impotency*. This is too dangerous a doctrine to be preached, but the general tone of the whole article shows the incapacity of the writer; lest, however, it should fall into the hands of unprofessional persons, we warn them of such a dangerous step, which would lead on to disappointment, impotency, and, perhaps, true insanity. Such patients are better treated by the formation of a sore on the penis, so as to baffle the act of masturbation, and to advise marriage would be great cruelty. The condition of the spermatic fluid is not likely to impregnate; but, should impregnation accidentally occur, we should have a progeny worthy of the editor of the *Lancet*, and his thoughtless, but not the less baneful, suggestions.

"To Medical Practitioners."

Under the above heading we find an advertisement in the *Exeter and Plymouth Gazette*, which announces the fact that the Guardians of the Barnstaple Union, are desirous of engaging the services of a medical gentleman, (duly qualified!) to undertake the care of the sick poor within the parishes of Horwood, Instow, and Wertleigh, who will be required to provide in all cases, attendance, medicines, and appliances, for the munificent salary of thirteen pounds a year! We are tempted to ask what do the Barnstaple farmers pay their servants? We understand the 6th district of the Mansfield Union has a medical officer for £15 per annum! We don't know whether to feel more annoyed with the members of our profession who accept such humiliating stipends, or with the Guardians for offering them. The equalisation of districts, and remuneration of Poor-law medical officers, as advocated in these pages, is the only remedy to redress a crying evil; and we ask our brethren to assist us, by respecting themselves in refusing such miserly emoluments as those announced above.

Bravo, Brady!

Mr. Brady, M.P., is tasting now the pleasure of a great success. He has carried his new Superannuation Bill, and has even resisted the Lords' amendment, so far as to deprive it of its worst feature. It is really a cause for congratulation that a medical member has been able to carry a measure like this; and it augurs well for the future. We congratulate the Profession, and, at the same time, thank the honourable member for the patience and zeal he has expended in the cause. It is said that, next Session, Mr. Brady will propose further Poor-law Medical Reform in a bill to emancipate our Poor-law brethren from the dictation of guardians. Whatever he brings forward in this depart-

ment is sure to be well considered; and we trust he will give it his full attention, rather than add one more to the proposed bills for amending the Medical Act. Still, any good measure of that kind may count on the support of the Poor-law Medical Reformer, *par excellence*.

Baby Farming.

A MEMBER of the Profession, during the past week, has received a circular couched in the following terms :—

SIR,—I beg to forward *(sic.)* myself to your notice as a person fitted either to take charge of or adopt a child.

I am a respectable householder, and can forward the best references. Hoping this will meet with your approval,

I remain, yours &c.,

Mrs. G. E.——

Burning the Dead.

WHAT to do with the slain in the war, has occupied the attention of the *Gazette Hebdomadaire*, and we are glad to see that some of the writers are prepared to advocate burning as superior to burying. The ancient plan had many advantages from a sanitary point of view, and we should welcome any discussion which might tend to remove the objections of modern Europe to any mode of disposal of the dead, that might be better for the living than that now practised.

The Harvest Field.

MUCH illness is generally produced at this time of the year, owing to exposure to the heat of the sun whilst in the act of following a laborious occupation in the harvest field, and to the incaution and recklessness, in consuming large quantities of badly-brewed beer, when the system is overheated by incessant and severe work. The more the thirsty harvester drinks, the more he appears to require ; and it is a well known fact, that stimulants are most injurious in hot weather, regardless of the stomach being in an unfit condition to receive them. A member of the Profession advises, we perceive—and we highly approve of the suggestion—that the plan adopted in tropical climates should be followed, of commencing work at an early hour in the morning, when labour is pleasant, and the atmosphere cool, giving up the middle of the day, when the sun is strongest and the heat greatest, to rest, and recommencing work in the evening, and following it until the decline of day. We believe more work would be done for the farmer, and that less risk to health would be incurred by the operative, if this plan were followed.

The Ulster farmers, we believe, supply their servants or "*shearers*," as they are called, with butter-milk, upon which they appear to work and get through the harvest, better than the English, who are allowed so much ale or beer to drink ; the butter-milk of Ulster being a cool and refreshing beverage which appeases thirst, whilst the ale seems only to increase it, tends to diarrhœa, and unfits the gleaner for continuous work. We recommend then for health's sake, the early morning and evening labour system in the harvest field, and the substitution of milk for beer.

The Cancer-Curer.

WE had occasion last week to comment upon the Bone-setter. Complaints which have reached us from various sources respecting another medical parasite, of the genus dangerous, actuate us in referring to one of the greatest pests which infest the healing art—the *cancer-curer*. As a rule, we find this form of charlatan differs from the bone-setter in practising more for notoriety than for actual gain ; accordingly, the mischief done in country places by this class of quack is often great. The salve generally employed is a compound, for the most part, of some arsenical preparation. We have known one cancer-curer who relied upon conium, and had Baron Larrey always on the tip of her tongue—for she was a female practitioner, who had the advantage of living in France. We have seen some lamentable cases, the perfidious result of such quackery. A woman with scrofulous enlargement of the cervical glands had the ill-luck to allow herself a few months ago, a respected correspondent informs us, to be persuaded to consult a cancer-curer, who at once pronounced the nature of the case to be "a chain of cancer." He commenced operations in the usual way, and in a few weeks gave his friend the grave-digger a job. It is surprising to find people foolish enough to be so deluded, for it might be naturally supposed that one fatal error should suffice to terminate such abominable quackery. The cancer-curer can soon relieve himself of all responsibility in the hour of danger, after he has done fatal mischief—which society is leniently disposed to term an error of judgment—the practitioner of medicine is called in, the work of the dastard ignoramus is concealed from him, and when his suspicions are aroused and he inquires, even denied, so that when the patient dies, he (the medical attendant) has no other alternative than to certify as to the death. If he refuse, and thereby cause trouble, or provoke inquiry, he is not only maligned, but injured ultimately in his practice—in fact, he is compelled to accede to unjust and criminal demands. We are happy to be informed there are many exceptions, and that we have members of the Profession who, at loss and risk, have put the cancer-curer in the dock. Would that all could unite as one to do the same ; but, as long as our existing laws are so defective, we must not expect the Profession to be secured, or human beings' lives to be safe. Our only regret is that legislators allow themselves to continue in ignorance of the surroundings of so important a Profession as ours ; and that they do not personally suffer from the effects of inadequate laws occasionally. We suppose society will continue to suffer at the hands of the cancer-curer and the bone-setter until wiser legislators know how to protect the people from them ; there is no other remedy we can recommend, unless when, a case of poisoning malpractice is established, for the doctor to direct the attention of the Crown to it, and, if they refuse to prosecute, to ventilate and expose through a press ready to assist in the suppression of quackery ; for the time is coming when the State must, with an iron hand, defend and support the members of our Profession in the exercise of their important duties.

Greenwich Union—"Canvassing is prohibited, and will disqualify."

THE quotation which heads this paragraph is taken from the advertisement issued by the Guardians of the Greenwich Union. That body required the services of a medical officer for the workhouse, and, from the tone of advertisement put forth, one would be led to suppose that experience, as well as qualification, should be essential

requisites of the selected candidate. Forty candidates offered their services, from which number six gentlemen were selected as being the most "suitable" for the appointment. Finally the successful candidate turned up by the election of Dr. J. W. Walker, whose qualification dates from last year.

Now, amongst the two score candidates that sought this appointment were many whose high testimonials of ability, plurality of diplomas, and years of experience entitled them to the consideration of the *acute* Guardians of the Poor of Greenwich; and our surprise at the *want* of such consideration by them is so great indeed that we consider some little explanation due to the unsuccessful candidates as to the grounds on which the appointment was made; more especially as a rumour has obtained, that, although canvassing in person was "strictly prohibited," canvassing by deputy was not only winked at, but appreciated in certain quarters.

Health of the Armies on the Rhine.

Besides the dreadful death roll of slain and wounded, we may soon expect to hear of disease causing ravages in the ranks of the hostile legions. Dysentery is commonly prevalent in the Rhine provinces of France and Prussia, as well as in Belgium, during July and August. The favourite treatment just now among French surgeons is bismuth, in full doses. Ipecacuanha seems to have failed with the medical men on the borders of the Rhine. If the war be not suddenly concluded, intermittent fever will probably in about a month from this time be epidemic. It is almost sure to be of a very low type. Then these fevers will assume a remittent form, and true camp fever will become established. It is not improbable that cases of typhus will also occur in numbers to cause anxiety, though other forms of fever will probably be most prevalent. We are, of course, presupposing that every hygienic precaution will be adopted; for neglect of any would be sure to give rise to proportionate loss. We speak only of what is to be expected under most favourable circumstances. As autumn advances, the weather will become a more potent element —rheumatic affections and diseases of the lungs then taking the lead. At present, the one question is, whether the camp will be exposed to heavy rains.

Reform of the Medical Council.

Should the medical authorities combine in the way we have sketched out in our leader to-day, there would remain the question of the constitution of the General Medical Council. This body has refused to reform itself, and, therefore, we should have to go to Parliament for a short bill with that object. As the Government offered to take into consideration this question, if opposition were withdrawn from its late Bill, it might, on some such provision coming into force, voluntarily be disposed to give the Profession what its Council refuses—representation.

The Vicar of Dorking has succumbed to the recent operation for cancer of the tongue.

Up to the present time the advantages of the war have been almost entirely on the side of the Prussians. It is reported that upwards of 500 students have joined the French Army as assistant surgeons.

The Committee on Hospital Organisation has adjourned until October.

The *Food Journal* says that much of the turtle soup given away during the last four months has been made of conger-eels.

All vessels arriving at Constantinople from the Sea of Azoff are quarantined in consequence of the breaking out of cholera at Taganrog.

No less a quantity than fifty-four tons of diseased fish were seized and destroyed in London alone during last month.

The Annual meeting of the New Sydenham Society will be held to-morrow (Thursday) at Newcastle-on-Tyne, for the election of officers and other business.

As Dr. Turrell, of Windsor, was driving out last Thursday, his horse took fright, and he was thrown violently from his carriage. He is now lying in a critical condition, suffering from concussion of the brain.

Lord Lyttelton, who has recently addressed a letter to the Universities upon the study of Greek, presided on the speech day at Malvern College last week, when the subject was again referred to.

It is with deep regret that the Profession will learn of the sad result of an attack of ophthalmia in one of its most accomplished members. Mr. Timothy Holmes has, from this cause, lost the sight of the right eye. Happily, the other eye has recovered, and Mr. Holmes will, it is hoped, soon be able to return to his work.

Messrs. Power and Vernon have been appointed to the newly created office of Ophthalmic Surgeons at St. Bartholomew's Hospital. This is a fact that deserves attention, for, if the old Royal hospital gives its special departments to those not on its staff, other hospitals reputed to be more liberal will surely follow the worthy precedent.

A sad accident occurred at the new Drainage Works at Hastings on Friday night, whereby three men lost their lives. It seems that the tank, which receives the sewage previous to its separation for making artificial manure by the A B C process, had not been opened the previous day, and when two men, named Nash and Fry, descended as usual to work, they were suffocated by carbonic acid gas. Mr. Porter, the chemist to the works, courageously went to the help of his subordinates, but shared a like fate, and his body was afterwards washed into the sea.

A strange case of hydrophobia is reported in one of the Sheffield papers. Last week two children were sleeping in a field, when a donkey, which had been grazing in the same enclosure, seized one of them by the leg, shook it savagely, and then carried the little creature several yards. So severely was the leg lacerated that the child was taken to the hospital, where convulsions quickly supervened and death put an end to its sufferings. The house sur-

geon, Mr. Algernon Taylor, gave it as his opinion that the donkey must previously have been bitten by a mad dog. The verdict was death from hydrophobia.

Correspondence.

DOCTORS AND TEETOTALLERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULR.

Dear Sir,—You have kindly on several occasions, permitted me—a non-medical man—to express my opinions on the above interesting subject in your journal. I again solicit at your hands the favour of this privilege, to express the gratification I have experienced recently from the perusal of two articles that have appeared in your issue of the 6th and the 20th inst. One from the pen of a "Physician," the other written by "George Ogilvie, M.D." Both communications confirm, very strikingly, the value of those views in relation to alcohol as an article of food and of medicine, that have been steadily impressed on the public mind for years past by the advocates of teetotallism. These, and some other papers that have appeared of late in our medical journals, confirm the views held by non-medical writers, as to the many dangers, not alone to health, but to the prosperity and happiness of the community also, which flow from the ignorant and unguarded use of alcoholic liquors that so universally prevails, and which, if they were caused by any other agency, would at once arouse such a spirit of determined opposition, as would soon banish the destroyer from these lands. No childish reasoning touching the rights of men who use this destroyer for private purposes of aggrandisement would be listened to for a moment, if a general sentiment did not prevail, that good in some form or other proceeded from the use of this poison—alcohol. This delusion teetotallers have been long striving to dispel. One of our chief impediments has always arisen and is still found, from the prevalent idea among medical men, that this article may be used safely, if not with advantage, if taken in *very small quantity*. Unfortunately, this necessary qualification or limitation never has been observed by any people. An individual here and there may keep within the line of safety. A nation never has done so, and never can do so. The only safety is in teetotalism. Hence, the pleasure which all the advocates of this sure means of safety from one of the greatest enemies man has to contend with, feel, when physicians come out of their shell to discuss this great question. I am much pleased when a learned writer such as Dr. Ogilvie, takes up the gauntlet against us, and in his endeavours to prove that we *may* be, or *perhaps are*, according to the axioms of exact science, or of medical knowledge, sometimes or somehow, not always altogether right in our radical conclusions, yet so weakly (as it seems to me) are we met in argument, and so cautiously is even the moderate use of alcohol recommended by such men, that no other conclusion could be come to by reasoning men, than this: that even acting in accordance with the advice of such writers as to so-called moderate use, it would be the safest course to abstain from the use of this poison altogether. The reading of Dr. Ogilvie's paper has afresh confirmed the sentiments which I had derived from other similar writers in my mind. These are, that for healthy men to tamper with alcohol, is extreme folly, and that even as a medicine, its value is so problematical, and its mischiefs so abounding, it would be best to discontinue it altogether. I think this is capable of proof from Dr. Ogilvie's own reasoning. Speaking of the action of alcohol, he says it has never "been thoroughly analysed." This is not the fault of teetotallers, and that its influence "requires more careful research." And he speaks of the "social, moral, and physical" evils it surely produces. He also tells us that we have "no very clear idea" of its effects on our system. I thought we had, in one respect at least, a very clear idea, and that is, its deteriorating effects on the brain, which has caused it to be named a "brain poison." I apprehend its smallest doses such as men call very moderate drinking, sensibly affect that organ, and that hence, arises *the* great danger of its use. It is not drunkenness that sends the noble ship to destruction, or that dashes one railway train into another. It is what is usually denominated moderate drinking that does this sad work, by disturbing the normal action of the brain. Dr. Ogilvie says, "we know nothing *positive* of its action in our system." Is not this opinion refuted by Todd and Bowman, who say that if alcoholic liquors were not speedily absorbed, the process of digestion could not go on in the stomach, their presence being fatal to that operation. And that Dr. Bowman is believed to be one of the first of living physiologists; therefore, first rate authority in this matter is proved by the fact that our Dublin Medical Colleges conferred on him the greatest honour in their power to bestow, because of his great acquirements, by making him an honorary member of their bodies?

The late Sir J. Simpson, a high authority, said to this effect at the meeting of the Social Science Association in Belfast in the Health Section: You may cleanse your lanes, and your streets, and your houses, as you will, but so long as you allow hundreds of publicans to pour filthy and poisonous alcoholic liquors down the throats of your people your labour will be in vain.

Dr. Ogilvie further informs us that "*if*" the quantity of alcohol taken be sufficiently small, no unpleasant consequences follow. Therein lies the whole difficulty of his position, and the all but impossibility of adherence to his rule. And after referring in plain words to the fact that "large bodies of men enjoy the most robust health without using them (alcoholic liquors) at all," he seems to endeavour to neutralize this fact by saying, "there is no sufficient evidence to show that their moderate use is *necessarily* unfavourable to health." The very danger of excess, which he clearly admits, proves that it is. He says, "a modicum of wine or spirits often restores the function of digestion." I place the positive dictum of Todd and Bowman to the contrary, against this opinion. With regard to his opinion that alcohol is useful in "debility connected with dyspepsia, hæmorrhage, or profuse discharges, certain stages of fever," and other complaints, I need only remark, that many men eminent in the profession, recommend an entirely different practice founded on long experience of its superiority.

I have now hastily but with intense interest, ran over Dr. Ogilvie's paper; and given as many extracts from it, in proof of my position as a teetotaller, that there is neither sense nor reason for the use of alcohol, as a common beverage, by men in ordinary health; and that, even as a medicine, its use were better superseded by other remedies,—as I dare venture to intrude on your space, by quoting. I thank him for his paper, although it expresses opposition to teetotalism, because I feel assured, that the more thoroughly this great question is examined, the more widely will its inestimable value to society, be recognized and acted on; and the less we shall hear about the difficulty of freeing the community from its evils. It will be treated as we treat incursions of Cholera, Plague, Fever, &c., as an enemy not to be reasoned with, or talked softly to, but expelled the land; just as our forefathers expelled wolves, because their presence was inimical to the public welfare. Or as our Irish landowner, did a few years ago, when cattle plague threatened them with the loss of some of their stock. They interdicted the importation of foreign cattle; and thus prevented the apprehended ruin. Now all these, and all other diseases put into one scale, would be weighed down as causes of human misery, by the effects of the Liquor Traffic, put into the other. No one is hardy enough to deny this; and yet we play with our enemy as little children, play with fire and other dangers, and allow sixty thousand of the men and women of these lands, to be annually carried away prematurely, to the dishonoured grave of the drunkard. And we permit six hundred thousand drunkards constantly to roam at large: a pest to their families, and a disgrace to their country. Are these evils to be spoken of with "bated breath and humbleness, !" or handled softly, with kid-gloves? The days are coming when society will be otherwise minded.

I hail with hearty goodwill, the advent of "A Physician" to our ranks; he speaks in favour of the Teetotaller's noble, but still too unpopular, work,—with right goodwill. May many other members of his profession hasten to assist us in getting entirely rid of this sworn enemy of our race.

Physicians,—your country expects this of you. You are the men set apart to warn us of the approach of every danger to health; has it any greater enemy than alcohol, to contend against? I am, &c.,

James Haughton.

35 Eccles street, Dublin, July 27th, 1870.

Gleanings.

The Correlations of Temperature, Pulse, and Respiration in Phthisis.

By Assistant-Surgeon Boileau, M.B., 29th Regiment, Quebec.

(From the *Army Medical Department Report.*)

There is at present a widely extended belief that the thermometer is, of all our aids to diagnosis, one of the most reliable in the detection of tubercular disease of the lungs. It is of the utmost importance that we should be acquainted with the real value of the instrument, as otherwise serious errors may occur; in addition to which the thermometry of disease will be unjustly impugned as a powerless means of diagnosis. The truth appears to be this, that the positive evidence of elevated temperature in a doubtful case of tuberculosis is of great value, whilst the absence of such elevated temperature is no proof that tuberculosis is not present. It is not even a proof that tuberculization is not in progress, it is not even a proof that any unfractuosities have not occurred in the lungs.

I have demonstrated that a person may progress to the stage of tubercular cavities in his lungs without exhibiting general elevation of temperature. And as this demonstration is of great consequence, I will give it *verbatim* from my case books, in order that the proofs may be scrutinised by those who are more experienced than I am.

I must admit, in deference to the opinions and experience of the well-known writers on the subject, that I have met with at least one rather exceptional case; but provided only that the circumstantial fidelity of the narrative is unquestionable, it alone must be of the greatest value, as a proof that tuberculisation of the lung may occur without general elevation of temperature.

Private J. McC., aged 27, service eight years, was admitted into the Regimental Hospital of the 29th Regiment in Hamilton, Canada West, on the 21st February, 1868. He had had very few entries in his medical history sheet. In 1863, dyspepsia gave him forty-four days in hospital, and in 1865, during the cholera season in Malta, he was ill for seven days with diarrhœa. During the last eight years, he had thus been only twice in hospital. His parents, brothers, and sisters, strong and healthy, and previous to this year he had been so himself. Latterly, he had become subject to colds, and within the month he had been troubled with pulmonary distress and cough. He was a fair-complexioned man, with blue eyes, and very white conjunctivæ; voice was hoarse.

February 24th.—Five observations have been made on this man's temperature—three mornings, viz., 98·6, 98, 98·2; and two evenings, 98·4, 98·2: average 98·2. His temperature is, therefore, normal. Judging from this fact, and from his general appearance, I do not expect to find anything very serious the matter with him.

He complains of a "cough and spitting," weakness, and a pain in the right hypochondrium when he takes a full breath. His voice is hoarse and weak, his breathing is quickened, the sputa is a mixture of froth and puriform detached masses, the skin is soft and delicate. Percussion yields a much duller sound from the left clavicle than from the right, and the infra-clavicular region of the left side is also duller than the corresponding right, but the difference gets less and less marked as we approach the mammary region. Percussion of the scapular region gives no reliable information. The respiratory sounds are very feeble indeed in the upper lobe of the left lung, whilst they are of normal strength in the right. Posteriorly they are rather feeble throughout the left, but positively puerile in the right; they are pure everywhere except under the clavicular and infra-clavicular regions of the left side, where there is an occasional but unmistakeable râle. The cardiac sounds are particularly clear and distinct. I suspect phthisis, but more than a suspicion is to-day unjustifiable; yet there surely cannot be any inflammation of mucous membrane, of pulmonary tissue, or pleura. His temperature this morning is 98·2, pulse, 108, respirations, 26; evening temperature 99·4.

February 25th.—Temperature, 97·8; pulse, standing, 132; lying, 108; respiration, 39; sputa of puriform masses floating in a thin fluid. Evening.—Temperature, 98; pulse, standing, 126 lying, 102; respiration, 32.

February 26th.—Temperature, 98·2; pulse, standing, 118, —lying, 96; respiration, 34. Evening.—Thermometer broken by accident; pulse, standing, 120, lying, 104; respiration, 36.

February 27th.—Pulse, standing, 120—lying, 100; respiration, 32. Evening.—Pulse, standing, 118, lying, 104; respiration, 36.

February 28th.—Pulse, standing, 116, lying, 102; respiration, 32. Evening.—Pulse, standing, 120, lying, 100; respiration, 36.

February 29th.—Pulse, standing, 120, lying, 100; respiration, 32. Evening.—Pulse, standing, 118, lying, 102; respiration, 32.

March 1st.—Pulse, standing, 112, lying, 116; respiration, 32. Evening.—Pulse, standing, 118, lying, 100; respiration, 32.

March 2nd.—Pulse, standing, 118, lying, 100; respiration, 32. Evening.—Pulse, standing, 120, lying, 100; respiration, 32.

March 3rd.—Pulse, standing, 120, lying, 102; respiration, 32. Evening.—Pulse, standing, 118, lying, 104; respiration 34.

March 11th.—There is distinctly less motion in the left than in the right side.

March 19th.—Sputa more puriform.

April 1st.—Less cough, less expectoration, rales diminishing, dulness less marked.—Temperature, 98·2; pulse, standing, 120—lying, 112; respiration, 26.

April 2nd.—Temperature, 98·4; pulse, 122 standing, 112 lying; respiration, 32.

April 3rd.—Temperature, 100·4; pulse, 116 standing, 108 lying; respiration, 32.

April 4th.—Temperature, 99·2; pulse, 122 standing, 112 lying; respirations 34.

April 5th.—Temperature, 99·4 pulse, 120 standing, 112 lying; respiration, 32.

April 6th.—Temperature, 98; pulse, 104 standing, 100 lying; respirations, 32.

April 7th.—Temperature 98·2; pulse, 112 standing, 110 lying; respirations,

Which gives an average for the week of—Temperature, 98·8; pulse, standing, 114—lying, 109; or a difference between standing and lying of only 5, and respiration 31.

April 8th.—Temperature, 97·8; pulse, 112 standing, 100 lying; respiration, 32.

April 9th.—Temperature, 99·2; pulse, 114 standing, 110 lying; respiration, 34.

April 10th.—Temperature, 98·0; pulse, 120 standing, 116 lying; respiration, 32.

April 11th.—Temperature, 98·0; pulse, 114 standing, 110 lying; respirations, 34.

April 12th.—Temperature, 98·2; pulse, 114 standing, 108 lying; respiration, 32.

April 13th.—Temperature, 98·0; pulse, 120 standing, 114 lying; respiration, 32.

April 14th.—Temperature, 98·2; pulse, 118 standing, 112 lying; respiration, 43.

Which gives an average for the week of—Temperature, 98·2: pulse, standing, 116—lying, 110; or a difference between standing and lying of only 4, and respiration 32.

April 15th.—Thermometer, 97·2; pulse, 116 standing, 100 lying; respiration, 32.

April 16th.—Thermometer, 97·6; pulse 120 standing, 116 lying; respiration, 32.

April 17th.—Thermometer, 98·2; pulse, 118 standing, 110 lying; respiration, 34.

April 18th.—Thermometer, 97·8; pulse, 120 standing, 116 lying; respiration 34.

April 19th.—

April 20th.—Thermometer, 98·8.

April 21st.—Thermometer, 98·6; pulse, 116 standing, 112 lying; respiration, 32.

Which gives an average for the week of—Temperature, 97.8; pulse, standing, 118—lying, 113; or a difference of only 4 between standing and lying; and respiration, 33.

April 22nd.—Thermometer 98·0; pulse, 120 standing, 114 lying; respiration, 32.

April 23rd.—Thermometer, 98·0; pulse, 120 standing, 116 lying; respiration, 34.

April 24th.—Thermometer, 98.2; pulse, 118 standing, 114 lying; respiration, 32.

April 25th.—Thermometer, 98·2; pulse, 120 standing, 116 lying; respiration, 32.

April 26th.—Thermometer, 98·0; pulse, 118 standing, 114 lying; respiration, 32.

April 27th.—Thermometer, 98·0 ; pulse, 118 standing, 114 lying.

April 28th.—Thermometer, 98·0 ; pulse, 118 standing, 114 lying.

Which gives an average for the week of—Temperature 98 ; pulse, standing, 119, lying, 115 ; or a difference between standing and lying of only 4, and respiration, 32.

April 29th.—Temperature, 94·4 ; pulse, 120 standing, 116 lying ; respiration, 32.

April 30th.—Temperature, 98·6 ; pulse, 120 standing, 114 lying ; respiration, 32.

May 1st.—Temperature, 98·2 ; pulse, 118 standing, 112 lying ; respiration, 32.

May 2nd.—Temperature, 98·4 ; pulse, 120 standing, 116 lying ; respiration, 32.

May 3rd.—Temperature, 99·4 ; pulse, 120 standing, 116 lying ; respiration, 32.

May 4th.—Temperature, 98·8 ; pulse, 120 standing, 116 lying ; respiration, 34.

May 5th.—Temperature, 98·0 ; pulse, 118 standing, 114 lying ; respiration, 32.

Which gives an average for the week of—Temperature, 98·5 ; pulse, standing, 119, lying, 115 ; or a difference between standing and lying of only 4, and respiration, 32.

May 7th.—Temperature, 98·6 ; pulse, 116 standing, 110 lying ; respiration, 32.

May 8th.—Temperature, 98·0 ; pulse, 114 standing, 110 lying ; respiration, 32.

May 9th.—Temperature, 98·4 ; pulse, 120 standing, 116 lying ; respiration, 32.

May 10th. Temperature, 97·8 ; pulse,—standing,—lying ; respiration, 32.

May 12th.—Temperature, 100·6 ; pulse, 120 standing, 116 lying ; respiration, 32.

Which gives an average for the week of—Temperature, 98·7 ; pulse, standing, 117, lying, 113 ; or a difference between standing and lying of only 4, and respiration, 32.

The diagnosis of phthisis having been made some time, he was brought before the half-yearly Invaliding Board, and on its recommendation would have gone home to England, had he not become so much worse before the invalids were sent from Canada. He was now obliged to take altogether to his bed. On the 13th of the month, he was attacked with a violent rigor ; his temperature rose to 104·6 deg., with a pulse of 124 lying, and respiration, 34. Next morning the existence of large cavities was too evident. The sputa became enormously excessive, of a purulent appearance, and the following observations were made:—

May 13th.—Temperature, 102·8.

May 14th.—Temperature, 99·6 ; pulse, standing, 108.

May 15th.—Temperature, 100·2 ; pulse, standing, 100 respiration, 32.

May 16th.—Temperature, 90·0.

May 17th.—Temperature, 100 2 ; pulse, 104 lying ; respiration, 28.

May 18th.—Temperature, 99·2 ; pulse, 104 lying ; respiration, 32.

May 19th.—Temperature, 98·8 ; pulse, 110 lying ; respiration, 34

Which gives an average for the week of—Temperature, 100 ; pulse, 107 lying, and respiration, 31.

On the 14th I made the remark—"The system has temporarily recovered from the shock, and is becoming tolerant of the diminished available lung tissue. This tolerance will, however, soon yield to necessity, and the lungs will soon be incapable of purifying the blood even to the extent required for his diminished body."

His evening temperature on the 15th was only 99·2 deg., and on the 18th 99·4 deg. On the 19th also his evening temperature was 99·4 deg.

On the 20th, the sputa was frothy and puriform, and very characteristic of phthisis. It is needless to dwell on the physical signs. The intestinal canal performed its functions regularly and healthfily. He seems to have no disease whatever but that of the lungs. The following observations were taken:—

May 20th.—Temperature 99·6 ; pulse 120 lying ; respiration 38. Evening.—Temperature 99·4.

May 21st.—Temperature 100·4 ; pulse 108 lying ; respiration 40. Evening.— Temperature 100.

May 22nd.—Temperature 99·2 ; pulse 110 lying ; respiration 36. Evening.—Temperature 100·2.

May 23rd.—Temperature 100·4 ; pulse 120 lying ; respiration 40. Evening.—Temperature 100·8.

May 24th.—Temperature 100·2 ; pulse 120 lying ; respiration 38. Evening.—Temperature 100·2.

May 25th.—Temperature 99·6 ; pulse 124 lying ; respiration 42. Evening.—Temperature 100·2.

May 26th.—Temperature, 99·8 ; pulse, 120 lying ; respiration 42. Evening.— Temperature 99·6.

May 27th. Died this morning, after—as well as we could judge—an illness of about three months and a-half in length. For the last 10 or 12 days he has been in a marked state of hectic, cheeks very much flushed, and suffering from profuse sweating and frequent rigors ; pulse very small and quick. A few days ago he expectorated a mass of tubercle about the size of a walnut. He has had but one solitary attack of hæmoptysis ; never complained much of thoracic tenderness.

Autopsy 30 hours after death.—Skin very white and semi-transparent ; body rather well nourished, there being a considerable quantity of subcutaneous fat ; muscles red and firm ; the cavities of both pleuræ almost entirely obliterated by adhesions of great tenacity. I never before removed the lungs from the body with such difficulty. Some portions of their substance I left attached to the thoracic wall. The pleuræ were converted into a muscular looking covering for the lungs, which was about one-eighth of an inch in thickness. This covering appeared to be a fleshy substance, but was in reality a tissue pervading with tubercle.

Having removed the lungs with as much as possible of their investing morbid membrane, which must effectually have prevented all gliding motion of the viscera, I found them thickly studded with grey miliary tubercles, giving to the cut section a very rough appearance and feel. In the left lung they pervaded every portion of the pulmonary tissue, giving whole square inches of the surface a perfectly grey appearance. Dispersed throughout the lungs there were also masses of yellow tubercle, from the size of a pea to that of a pigeon's egg, and varying from a soft consistence to the hardness almost of cartilage ; in fact the apex of the left lung was more like a piece of cartilage than anything else. In the upper lobe of this lung I found a cavity the size of a walnut, and there were besides several anfractuosities. The right lung was about as far advanced in disease in its upper lobe as the left was in its lower, and the lower lobe of the right lung had by far the smallest quantity of deposit, and that of the grey miliary character, without any yellow tubercle ; so that if we had placed the apex of the right lung under the base of the left, and made a clean section from top to bottom through both, we should have had a successive gradation of developed disease presented to us. At the top complete replacement of lung tissue by morbid product of the most developed character, resulting in utter destruction of parts ; lower down the tissues pervaded by the grey miliary first form, with a good deal of the yellow, lower still (top of right lung), the grey universally pervading with very little yellow ; lower still nothing but the grey form, and lower still a few cubic inches of what might be called the available portion of the pulmonary organs. And so with the pleuræ. At the top (upper lobe of left) the lung was so solidly united to the parietes that the knife only could separate it ; lower down the fingers could do this, but with great difficulty ; lower down (upper lobe of right) this was easier to do, and lower still there was a portion of the pleural cavity existing.

The heart was very fat on the surface, but was otherwise quite healthy ; liver and spleen quite normal ; no enlargement of the mesenteric glands.

Remarks.—The physical signs and the diagnosis were most satisfactorily verified by the *post-mortem* examination. It appears to me certain that a miliary deposit had taken place to a very considerable extent when he first presented himself at hospital. Yet at this time his morning and evening temperatures were normal ; in fact until the 11th of May his temperature, with remarkably few exceptions, was always normal ; but there is one remark to be made here of paramount importance. I am here speaking of his temperature between nine and ten o'clock *every morning. Unless the time of a thermometric observation on a patient is given, apparently conflicting theories will be announced, and endless controversy will be the result.* Temperatures taken before noon are all-important for one reason out of many—viz., that it is in the morning that invaliding boards and consultations generally take place. Observations taken at such times are of value, only in comparison with others taken at the same time of day. I may

state, however, that I have taken several normal evening temperatures of phthisical patients.

The pulse in this case was almost invariably over 100 lying, and I believe that the rapidity of the pulse to be more constant in phthisis than the elevation of temperature. A peculiarity (?) in his pulse was the small increase of rate when he stood. This, however, has been stated to be very generally the case in phthisis. The respirations were almost invariably over 30 lying or standing. With all this, there was I believe no inflammation in the lungs, nor had we evidence of general fever. Why should we necessarily seek for such? I have seen morbid deposit in the penis, and removal of that deposit by ulceration, which destroyed nearly half the organ, where the average temperature of 54 morning and evening observations was 98·4 deg. 40 of the temperatures being 99 deg. and under, the highest taken being 100·4 deg. three only exceeding 100 deg. I have seen syphilitic sarcocele terminating in sloughing, where the average temperature given by 28 observations was, for morning 97·5 deg. one only exceeding 99 deg. and for evening 98·3 deg. two only exceeding 99 deg.; and I have, in like manner, seen necrosis of the tibia with extensive subcutaneous infiltration, and a large number of buboes, &c., without any elevation of axillary temperature. I do not mean to say that increased heat is not a strong corroborative evidence of the existence of phthisis. I think it is, but I believe that it is hazardous to assert that because a patient's temperature is not above 99 deg. that he is not phthisical. I think it proved that a considerable deposit of tubercle may, under favourable circumstances, take place in the lungs without giving rise to elevation of temperature; and I may here state my opinion, founded on about 30,000 observations, that the maximum of axillary temperature in a healthy man is 99 deg.

There are some particular points of interest in the case which I have given, but as they have no bearing on the question of the correlation of temperature, pulse, and respiration, I must pass on to a consideration of the next case, which justifies me in expressing the opinion that tuberculosis may be in progress without causing a diagnostic increase of natural heat.

(To be continued.)

Medical News.

Royal College of Surgeons of England.—The following gentlemen, having passed the final examination for the diploma, were duly admitted Members of the College at meetings of the Court of Examiners on the 28th and 29th ult.:—Henry Bennett Bailey, L.S.A., Sutton St. Edmunds, Lincoln; William E. Battersby, M.B. Dub., Killarney; H. W. Langley Browne, West Bromwich; Joseph Hirst Clarke, Sheffield; Charles Clay, Dewsbury, Yorkshire; Henry Edward Dixon, Watlington, Norfolk; Robert T. S. Eagar, Andenshaw, Lancashire; George Fenton, L.S.A., Great Smith street; Alfred W. Harding, Percy street; William Hardman, Blackpool, Lancashire; Henry Jukes Hibberd, Peckham; Francis Hollingshead, Coventry; Hubert Ernest Hudson, L.S.A., Cranbrook, Kent; Joseph Hunt, Hopwood Allchurch; Thomas Llewellyn Lloyd, Wrexham, North Wales; William Henry Lovejoy, M.D. New York, Portman street; Francis Ottley Lovell, Kilburn; Jameson John Macan, Cheam, Surrey; Alexander Mitchell, Birmingham; George P. O'Farrell, M.D. Dub., Boyle, Co. Roscommon; Charles Bagge Plowright, L.R.C.P. Edin., North Wotton, Norfolk; Walter Rigden, L.S.A., Canterbury; Edmund B. Ravenhill, Arlingham; Bernard John Shaw, L.S.A., Attercliffe, Yorks; Arthur William Smith, L.S.A., Halifax; Charles Wait Smith, Jamaica; George E. K. Thorpe, L.S.A., Sheffield; Lawrence Kingston Times, Manchester street; Thomas H. F. Tothill, L.S.A., Topham, Devon; Charles William Vickers, L.S.A., Huddersfield; Edmund S. Warburton, Betley-Crewe; George Wilson, L.S.A., Claverton street.

The following candidates, having passed the required examination, obtained their diplomas in Dental Surgery at a Board of Examiners held on the 2nd inst.:—Edward Bartlett, Connaught square; Charles Lane Clark, Harley street; Francis Frederick Ebbetts, Tottenham; George Graham Forster, Durham; Isidor Isaac Lyons, St. John's-wood; Charles Claude Rogers, Cork street, Burlington Gardens; Richard William H. Tucker, Truro, Cornwall.

University of London.—The following gentlemen have passed since the publication of the last list in our issue of the 3rd instant:—First M.B. Examination.—(*Entire.*) *First Division:*—George Harry Barfoot, Henry James Benham, Sidney Coupland, William Smith Greenfield, Charles Atkinson Nankivell, and Walter Ottley—of University College; George Birt, Sydenham College, Birmingham; Ebenezer Geer Russell, Guy's Hospital. *Second Division:*—Thomas Barlow, B.Sc., University and Owens Colleges; Philip Henry Bindley, Richard Goodwin Breeze, Leonard Cane, Walter Bernard Cornelius, Charles Washington Shirley Deakin, Rickman John Godlee, B.A., Thomas Anthony Aloysius M'Cann, Ebenezer John Ramsay, and Arthur Rich Saunders—of University College; Cuthbert Hilton Golding Bird, B.A., Benjamin Neale Dalton, Thomas Eastes, and George Henry Percival—of Guy's Hospital; Gerald Bomford, John Alexander Cockburn, Andrew Duncan, Joseph Henry Phillpot, and William Rose—of King's College; Thomas Carleton Railton, Owen's College and St. Bartholomew's Hospital; Henry William Saunders, St. Thomas's Hospital; Herbert Taylor, St. Bartholomew's Hospital. *Excluding Physiology.—Second Division:*—David Arthur Davies, University College; William Williams, Guy's Hospital. *Physiology only.—Second Division.*—John Thomas Darby, University College; Robert Eardley-Wilmot, King's College.

Health of the Quarter.—The Registrar-General's quarterly return of the marriages, births, and deaths registered in the divisions, counties, and districts of England states that in the United Kingdom the births of 275,273 children and the deaths of 162,750 persons of both sexes were registered in the three months ending on the 30th of June, 1870. The natural increase of population was thus 112,523. The number of persons married in the quarter ending the 31st March, 1870, was 108,202. The resident population in the middle of 1870 was estimated at 30,838,210, that of England and Wales amounting to 22,090,163, of Scotland to 3.222,837, and of Ireland to 5,525,210. The corrected death-rate of the quarter was 22·1 per 1,000; the birth-rate 37·1; the marriage rate for the previous quarter 15·5. The annual birth-rate was somewhat above the average; it was 37·00 in 1,000. Mr. Glaisher shows that April came in cold; that the temperature then rose, and was high until near the end of the month. Anon cold came, and rain fell in small quantities in different parts of the country, until May had fully set in; then the weather became warm and dry, and full of sunshine until nearly the end of June, when the cold, changeable fit returned, and brought a little rain. These months were almost rainless at Greenwich; only 1·2 of rain fell on 15 days out of 91, against an average of 5·8 in. Over the country, especially in the north, the rainfall was not so inconsiderable. Mr. Glaisher estimates the mean rainfall at 3·37 in. The mean temperature at Greenwich was 54·4 Fahrenheit. The mean temperature was 12·4 deg. centigrade; about 1 deg. over the average. The air was unusually dry. Taking saturation at 1·00, the degree of humidity was ·70, whereas it was ·76 on an average of 29 years. The air travelled horizontally at the rate of 10 miles an hour. In metric measure at Greenwich, the rainfall of three months was 3 centimetres, the average being 15 centimetres; for the country generally the rainfall was about 8 centimetres. The wind travelled horizontally at the rate of 16·5 kilometres an hour. The mortality, 22 in 1,000, did not exceed the average of the season, which lies between the extremes of winter when it is highest, and summer when it is lowest, unless some great epidemic prevails. 121,246 persons died in the 91 days; more by 7,508 than the average of the preceding three spring quarters. The annual mortality per 1,000 was 22·81 in the chief town districts, less than the average of ten preceding years by 0·61; while in the other districts of small towns and villages the mortality was 21·02, or 0·69 above the average. This may probably be interpreted to imply that the sanitary measures now in operation in towns are producing an effect which is counteracted by the increase of neglected nuisances in the country. This establishes the necessity of covering the whole area of the kingdom with an effective sanitary administration. The mortality of London has increased in the three last spring quarters; there has been a decrease in the mortality of Birmingham, Manchester, Salford, Sheffield, Hull; an increase in Bradford among the 17 English towns of the first magnitude. The mortality in the 50 towns of second magnitude was at the rate of 21·9 in 1,000; among these towns those of lowest mortality were Dover, Southampton, Coventry, Birken-

head, Ashton-under-Lyne, South Shields, Carlisle, where the mortality ranged from 13·1 in Birkenhead to 28·8 in Carlisle. Among the towns of highest mortality are Maidstone, Reading, Oxford, Cambridge, Exeter, Stoke-upon-Trent, Macclesfield, Wigan, Bolton, Huddersfield, Halifax, Swansea, where the mortality ranged from 23·5 in Reading to 27·0 in Exeter, and 31·6 in Halifax. These high rates of mortality should be inquired into specially by the local authorities. Measles, scarlet fever, and fever have been epidemic in Halifax; but the diseases that prove so fatal in Exeter are not so apparent. In 17 large English towns the rate of mortality from the seven principal zymotic diseases, namely — small-pox, measles, scarlet fever, diphtheria, whooping-cough, fever, and diarrhœa was lowest in Sunderland (1·1) and Leicester (1.4), highest in Sheffield (4·8), Bradford, and Bristol (5·6) per 1,000, At the present time it is important to watch closely the mortality of infants. In the healthier districts of England it appears by the Life Table that out of 100 born alive 10 die in the twelve months following. Now, the births in a quarter have been compared with the deaths in the same time under *one* year of age in 17 large English towns, and the deaths are 15 to 100 births; five are killed by various causes in these towns in addition to the ten that die in healthy country districts. In this quarter the infants fared worse in Bradford, Liverpool, Manchester, Leeds, Bristol, where from 17 to 18 out of 100 born alive died; best in Portsmouth, Sunderland, and Sheffield, where from 11 to 13 infants under 12 months of age died to 100 born alive. It may be of use to state that no epidemic disease prevailed to any extent during the three months of April, May, and June, in Lowestoft, Herne Bay, Eastbourne, Sidmouth, Exmouth, Ilfracombe, Tenby, Aberystwith, Llandudno, Rhyl, Malvern, Buxton, Matlock, and Harrogate. Scarborough, Yarmouth, the Isle of Wight, Weymouth, Torquay, Penzance, Weston-super-Mare, Southport, and Tunbridge experienced outbreaks either of scarlet fever or of some other zymotic malady, but in none of these places was any epidemic very fatal except in Penzance. It is thus fortunate, the Registrar General concludes, that, while a sanguinary war is raging on the Continent, tourists find the English watering-places in a comparatively satisfactory state—in fact, much healthier than the places of resort abroad, where sanitary science has made even much less progress than in England.

The Edinburgh University Club.—On Monday, the 1st instant, the Members of the Edinburgh University Club dined at Hampton Court. In the absence of Dr. Sievcking, one of the Vice-presidents, from indisposition, the chair was occupied by Dr. Alexander Halley, who recapitulated the objects of the Club, dwelling particularly on the opportunities its periodical *réunions* afforded for the revival of early College associations, and the maintenance of good-fellowship among the widely-scattered *alumni* of Edinburgh.

Vaccination.—The Privy Council have presented Mr. J. W. Dryland, M.R.C.S., of Kettering, a gratuity of £22 4s., and to Mr. W. Conway Hind, of the Swineshead District of the Boston Union, the sum of £7 7s. for successful vaccination.

The Northampton Lunatic Asylum.—The Annual Report of this institution has just reached us, and, after a careful perusal of its pages, we congratulate the Committee of Management generally, and the Medical Superintendent and Secretary particularly, upon the excellence of the arrangements for the employment and amusement of the large number of patients the Asylum contains. Husbandry and gardening are extensively patronised; and even the question of "What shall we do with our sewage?" is disposed of in miniature, by its distribution by gravitation over the land, which is much enriched thereby. The number of patients in the Asylum during the past year was 573, the sexes being about equal. The deaths were somewhat in excess of previous years, which is easily accounted for by the large proportion of extreme cases admitted. Some time ago we directed attention to the great want of accommodation for the insane of the middle class—for those who cannot afford to pay heavy sums, and who are still above being paupers. We are happy to find this *desideratum* is accomplished by the additions made to the buildings of this institution, where the payments vary from one guinea per week, according to the circumstances of the case and the accommodation required.

Sanitary Reform.—It is stated that the managers of the metropolitan asylums have resolved to retain possession of the fever hospital at Hampstead in order to meet the requirements of the metropolis, which is threatened with an epidemic of typhus fever. Alas! no fever hospital will meet the requirements of this metropolis. The cures effected at the hospital will be but a poor compensation for the deaths of thousands which must occur from the effects of dirt, muddle, and "consideration" before next Session. What the metropolis really requires is a simplification of our Sanitary Acts and the establishment of some less complicated machinery than that which local authorities now neglect to put in action. It also requires a Home Secretary who will not only take a deep interest in matters of domestic concern, but will also energetically, and without loss of time, carry out those reforms which are so urgently required. Our lives should be to the Home Secretary what sovereigns are to the Chancellor of the Exchequer. A waste of the former is far more serious than a waste of the latter. The terrible mortality from scarlet fever which made so many homes desolate last year, and has since become chronic in the metropolis, should have made sanitary reform one of the principal measures of the Session now expiring; but it is too late now. No ray of sunshine will clear the shadow of death that wraps in misery and gloom the dens which form the dwelling place and dying place of so many of the poorer classes in this country. Perhaps when we have educated them they will be more content to live like pigs and die like dogs; in the meantime it only remains for them to make their bow to the Home Secretary and thank him for the kind "consideration" he has bestowed on their case. "Ave Cæsar, morituri te salutant!" is more likely to be his greeting at the close of the Session then "Well done, thou good and faithful servant!" which expression he modestly informed his audience at the Mansion-house on Saturday he expects to hear addressed to himself and the other members of the House of Commons as a reward for his labours.—*Pall Mall Gazette.*

Prizes at the French Academy.—M. Chenu has obtained the statistical prize for his Medico-Chirurgical Statistics of the Campaign of Italy in 1859-60. The prize for Medicine and Surgery has been conferred on M. Junod for his Hæmospasia, £100. M. Luschka, of Tubingen, for his Topographical Anatomy, £80. MM. Paulet and Sarazin, for the same subject, £80. Dr. H. Roger, for his Chorea in Children, £60. M. Maurin, for his Typhus among the Arabs, £60. M. Knoch, of St. Petersburg, for his Bothriocephalus Magnus, and M. Saint Cyr, for his Tinea Favosa among Domestic Animals, £40 each. Other prizes are conferred for investgations and proposals to prevent the evil effects of certain unhealthy trades, viz.—M. Pimont, for his Plastic Calorifuge, £100. M. Charrière, for his Apparatus for saving shipwrecked crews. The Cuvier prize has been awarded to Ehrenberg. The Barbier prize has been divided between M. Mirault, of Angers, for his Temporary Surgical Occlusion of the Lids in the treatment of Ectropion arising from a Cicatrix; and Dr. Stilling, of Cassel, for the improvements introduced by him in Ovariotomy. The Godard prize has been presented to Hyrtl, Vienna, for Genito-Urinary Organs of Fishes.

Association of Medical Officers of Health.—At the annual meeting of this Association the following officers were elected for the year ensuing:—President, Dr. Robert Druitt; Vice-presidents, Dr. Aldis, Dr. Buchanan, and Dr. Woodforde; Treasurer, Dr. Aldis; Secretaries, Dr. J. Northcote Vinen and Dr. Thomas Stevenson; General Purposes Committee, Drs. E. Ballard, H. Letheby, W. Hardwicke, W. T. Iliff, Thos. Sutton, J. J. Rygate, Mr. Jno. Liddle, and Mr. C. F. J. Lord.

Apothecaries' Hall.—At a Court of Examiners held on the 4th inst., Messrs. William Frederick Richardson Burgess, of Bethnal-green road; James Tompsett, of St. Leonard's-on-Sea; and Samuel Walker, of York, having passed the necessary examinations, were admitted licentiates of the Society of Apothecaries; and Messrs. Arthur Culver James, of Guy's Hospital; William Odell, of St. Bartholomews Hospital; William Rendall, of Guy's Hospital; and William George Watson, of University College Hospital, passed the primary professional examination.

Fever in London.—The following are the numbers of cases admitted into the London Fever Hospital during the last few weeks:—There were admitted during the week ending May 7th, 2 cases; 14th, 6; 21st, 10; 28th, 8; June 4th, 4; 11th, 14; 18th, 9; 25th, 10; July 2nd, 13; 9th, 18; 16th, 36; 23rd, 13; 30th, 8.

Vaccination.—Dr. Snow says in his last monthly report as City Registrar of Providence, in America:—The experience of the past winter has only been a repetition of the old, well-established story in this city—the absolute protection from small-pox afforded by vaccination, and the importance of re-vaccination. The small-pox has been brought into Providence no less than five times since last November from other places. The first time the disease was extensively spread before it was recognised; but was arrested completely after about thirty cases, mostly modified, had occurred. In the other four instances the disease was confined to the parties who brought it from other places. Vaccination has been quite general in the city during the past winter, and we may say confidently that there are few, if any, places in the country where the population is so well protected against small-pox as in Providence.

Fatty Degeneration of the Placenta. By Andrew C. Kemper, A.M., M.D., of Cincinnati, Ohio.

September 25th, 1868, Mrs.———, æt, 33, had always enjoyed excellent health; uterine functions perfectly regular; nearly two years after her marriage, she supposed herself for the first time pregnant, her catamenia having ceased. She experienced all the usual effects of that condition, without any unfavourable symptom, until February. About the first of January she had suffered for several days from mental anxiety, and in the second week in February she became aware of a sudden diminution in her size, after which she was not larger than previous to her conception. There was no discharge or other sensible cause for this. About the middle of April some dribbling hæmorrhage occurred, and continued for a couple of weeks. Medical advice was sought, but without any practical solution of the difficulty, except to convince her that she was mistaken in the supposition that she had been pregnant. The hæmorrhage returned on the 19th and 20th of May, and on the 30th, after two or three sharp labour pains, a blighted fœtus, of apparently two months, was expelled from the uterus. Membranes were of a dark, dusky, modena colour, unbroken, and showing the form of the fœtus through them. Placenta normal size for fœtus of two months, entirely composed of fat, but resembling on its uterine surface the outer layer of fat on the ribs of beef, and was unctuous to the touch. Uterine surface presented two irregularly shaped, branch-like bloody streaks, three lines broad, and an inch and a-half long respectively, very nearly at right angles with each other. Excepting these streaks, there was no appearance of vessels upon or within the placenta. The anterior wall of the abdomen seemed to be of more than ordinary thickness. The pelvis was of good shape and well developed. The lochial discharge ceased on the fourth day. On the sixth day there was a sudden gush of blood from the uterus that blanched the cheeks and lips of the patient. Since then there has been no discharge. The convalescence has been rapid, and the patient has been going about the streets for several weeks apparently in perfct health.—*American Journal of the Medical Science.*

A Case of Dislocation of the Humerus from Sneezing. Reported by P. H. Garritson, M.D., Macomb, Ill.

I was called early one morning to see John H., a carpenter by trade, aged forty-two, who, while combing his hair, preparing for breakfast, suddenly sneezed and dislocated the head of the humerus into the axilla. By grasping the arm close up to the axilla with my left hand, and with my right manipulating the elbow, I succeeded, with but little difficulty, in reducing the dislocation. The after treatment consisted simply in supporting the arm in a sling for a few days.

Now, the rationale of the dislocation I am not certain that I know, but the reader may judge for himself. He says he was combing his hair with his right hand, and was holding his left arm nearly on a line with the coracoid process of the scapula. In the act of sneezing we naturally throw the head forward, and the arm at the same time being held in the position he had his, the muscles being relaxed, save sufficient to retain the position, through the involuntary sudden contraction of the deltoid, brachialis anticus and biceps muscles, the elbow will raise and the head of the humerus be correspondingly or proportionately depressed. This we think must have been the cause of the dislocation. Never having heard of a dislocation being produced under such circumstances, I have thought a note of it might not be uninteresting to some of the profession.—*Medical Archives.*

DECAPITATION IN HANGING.

We understand that an investigation was held, by order of the Lord Lieutenant on Tuesday last at the Richmond Bridewell, by Drs. Lentaigne and Hatchell into the occurrence which took place at the execution of the convict Carr. The whole question to be decided was as to whether the drop of 14 feet was so long as to involve the unfortunate result. It seems that Mr. Price, the gaoler at Kilmainham, had expressed to the governor of the Richmond prison and to the Board of Superintendence that the rope would break, or else decapitation would take place, and it seems very strange that this warning was not communicated to Dr. Minchin, the surgeon of the jail. At the coroner's inquest, subsequently—

Dr. Minchin was, of course, examined, and took his stand firmly on the investigations of Professor Haughton to which we alluded in our last. It appears that the long drop is not so much of a novelty in Ireland as we had been led to suppose. Dr. Minchin mentioned several cases in which it had been used, and notably referred to the execution of Burke at Clonmel some years ago. The convict in this case was 12 stone weight, and received a drop of 16 feet, which, according to Professor Haughton's formula, would give a shock of 2,688 lbs., or nearly a ton and a quarter, and yet decapitation did not follow.

A member of the Board of Superintendence of the City Prison, Hugh O'Rorke, J.P., of New Row, a man of great intelligence, and well skilled in matters relating to manufacture of ropes, gave most important evidence. He showed that the rope (in Carr's case), owing to the peculiar way in which its strands had been laid, was incapable of the smallest degree of resiliency, a property which is possessed by all good ropes, and he attributed the accident to this fact, and not to the length of fall at all. If it had been properly made it should have "sprung" about two feet—*i.e.*, elongated by its elasticity and shortened again. Out of several ropes on the table he picked out one and said that from its make he would insure its having the necessary spring; whereupon Mr. Price, of Kilmainham, at once remarked, "that is the very rope with which Kilkenny was hung, and it actually did become elongated considerably at the moment of the fall, and sprang back again!" The Commissioners looked upon Mr. O'Rorke's evidence as very satisfactory, and most valuable, as establishing the fact that the length of drop recommended by Dr. Minchin, in accordance with the rule enunciated by Professor Haughton, was *not excessive*, and that the accident was not attributable to any error of calculation on his part.

NOTICES TO CORRESPONDENTS.

Notice to Subscribers.—*The Publishers beg respectfully to remind those Gentlemen who have not paid their Annual Subscription, now overdue, that the most convenient mode of remittance is by Post-office Order, or cheque, which should be made payable, in England, to Albert Alfred Tindall; Ireland, Moffatt and Co.; Scotland, Maclachlan and Stewart.*

"FREE TRADE IN SURGICAL INSTRUMENTS."

To the Editor of the "Medical Press and Circular."

Sir,—I have just had my attention called to an article in your impression of the 22nd of June last, entitled "Free Trade in Surgical Instruments," in which you comment very freely on the opinion expressed by the Nottingham and Notts Chemists' Association, relative to the issue of Maw, Son, and Thompson's catalogue to surgeons.

In justice to the members of that Association, will you allow me to say that you appear to be labouring under an erroneous impression with regard to the decision in question.

The chemists of Nottingham, like other towns, are not, and have no wish to be, vendors of surgical instruments. They think, with you, that Maw, Son, and Thompson are perfectly justified in sending out price-lists of such things to the Profession, and would support them in such

BELFAST BOARD OF GUARDIANS.

ALLEGED DISCOURTESY TO A MEDICAL OFFICER.

With reference to the charge made by Dr. Rea against Mr. Thomas Wilson, one of the relieving officers, for discourtesy and impertinence, Dr. Rea appeared by direction of the Board to substantiate his statements. It seems that a man named Russell had applied to Mr. Wilson for admission into the hospital. Mr. Wilson, knowing him to be a person of bad character, sent him to Dr. Rea with a line inquiring if he was able to work. Dr. Rea scored out the words "fit to work," and submitted that he was "ill with rheumatism." Mr. Wilson again sent to know if he was able to do work, and Dr. Rea struck out the words. This was repeated four times, and on the fourth time Dr. Rea wrote on the back of the ticket that the patient required urgent medical treatment. Dr. Rea also wrote to the Board, stating that Mr. Wilson had gone out of his sphere to treat him discourteously, and even impertinently.

The Chairman.—The point now is, was Mr. Wilson right or wrong in insisting on getting an answer as to whether the man was fit to work or not?

Mr. Gaffikin.—What was the answer the doctor gave you when you inquired whether he was fit to work or not?

Mr. Wilson.—That he was ill from rheumatism.

Mr. Ward.—A relieving officer has great discretion and great responsibility and I think it his duty to know whether a man is able to work. It strikes me it was a very proper question for him to ask. The whole question of relief or non-relief turned upon the answer; because if a man was able to work and got hospital relief, and it turned out upon the doctor's certificate that he did not require the relief, it would be very improper to put him on the rates.

The Chairman.—Did you, Dr. Rea, intend, in this case, that the man should be sent to the hospital?

Dr. Rea.—Certainly, I did.

Mr. Wilson.—Well, then, Sir, I would like to know if he was under medical treatment when in this house?

Chairman.—I don't think that's the question

After some further discussion it was arranged that some other form should be prepared to obviate the difficulty.

Dr. Rea said he had no objection to the matter being settled, and the subject then dropped.

The remaining business was routine.

CARRICK-ON-SUIR DISPENSARY COMMITTEE.

The business of the meeting was in reference to the complaint made by Mr. Murphy, apothecary, about certain medicines supplied to the dispensary, by the contractor, and which Mr. Murphy said were unfit for use.

Dr. Fitzgerald explained that the medicines complained of were not quite up to the mark, but they were dispensed without any bad effect.

The Hon. Secretary explained that the matter would have been brought under the notice of the committee before this, but there was no meeting of that body on the 13th ult.

The following resolution was then adopted by the meeting:—

Resolved—"That inasmuch as it appears that the medicines complained of were used before the meeting on the 13th of June, and the medical officer having stated that he cautioned the contractor at the time, and that all the medicines supplied before and since have given satisfaction, that no further action be taken on the matter, but we recommend the medical officer to get a written report from the apothecary should such a thing occur in future."

The meeting then adjourned.

SLIGO BOARD OF GUARDIANS.

VOUCHING OF REQUISITIONS OF COMMITTEES.

A requisition was read from Dr. Burrows for medicine and medical appliances for the Riverstown Dispensary.

A guardian asked if the dispensary committee had signed the application.

Mr. Kerrigan, speaking from his experience, believed that if those requisitions were to await a meeting of the dispensary committee, the dispensary would be often left without medicines.

Mr. M'Cloughry understood that it was not legally necessary to have them signed by committees.

Mr. C. G. Jones believed it was, but of necessity they did not ask to have it done.

Mr. Jeremy Jones said that out of the thirty or forty gentlemen that constituted the committee of management for the Sligo Dispensary, on a late occasion no member attended a meeting but himself.

The requisition was passed, and the matter dropped.

OMAGH BOARD OF GUARDIANS.

COMPULSORY VACCINATION.

The following letter from A. H. Robinson, Esq., Medical officer, Fintona District, addressed to Mr. M'Knight, Clerk of the Union, was read before the Board by the Chairman:—

"Fintona, July 23, 1870.

"Dear Sir,—James M'Connell, child of James M'Connell, born and registered in Dromore district, was vaccinated by me successfully in October, 1869, the child being then and since resident in this district. The father was summoned to Trillick Petty Sessions in May last, for not having his child vaccinated in Dromore, although he had not resided in that District since May, 1869, and fined

in his absence and has since paid 2s. 6d. fine and costs. The mother has been with me to-day complaining of the hardship, and I thought it right to lay the facts before you for the information of the Board of Guardians who will, I hope, take the case into consideration. Mrs. M'Connell states that on their getting the summons, they went to Dr. Marshall and showed him my certificate of successful vaccination of the child."

Mr. James Mackay considered that it was a case of great hardship, and wondered very much why the case had been proceeded with if it was true that the certificate of vaccination had been shown to Dr. Marshall.

Mr. Stack remarked that if M'Connell had attended the Petty Sessions and shown the certificate to the Magistrates the case would have been dismissed with costs against the doctor.

Mr. Greer said that assuming the woman's story to be true, it was very wrong of the doctor after having seen the certificate to make no remark about it at Petty Sessions.

Mr. Stack recommended that a statement of the allegation made by M'Connell be sent to Dr. Marshall and that he be directed to pay the costs which had been incurred in the proceeding.

Captain Buchanan was in favour of the Doctor being communicated with respecting the matter before anything should be put on the minute books.

This course was unanimously approved of by the Board, and the Clerk was directed to write to Dr. Marshall regarding the matter.

CLAREMORRIS UNION.

Mr. Henry French, pursuant to notice of motion, proposed that the salary of Dr. P. B. Reynolds, Medical Officer of the Claremorris Dispensary District be increased from £75 to £100 per annum, same being the salary paid in the other dispensary districts of the Union.

Mr. F. A. O'Malley seconded the resolution, which was agreed to without a division.

Mr. James E. Treston proposed, and Captain Sheffield seconded, the following resolution, which was also adopted unanimously :—"That whenever a Medical Officer in this Union absents himself in future from the discharge of his duties, unless such absence is occasioned from illness, the Medical Officer will be required to defray the expense of a competent substitute."

ENNIS UNION.—Wednesday.

Medicine Contract.—Several tenders came before the board for the supply of the above, the lowest being that of Messrs. Hunt, Dublin. Drs. Dillon, Enright, and Courtnay said that none of the parties whose tenders were before the board could possibly supply the description of medicine required by the Commissioners at such a low price, but expressed their conviction that Messrs. Hunt's medicine was quite as good as what the others could supply, though proposed at a lower rate.

The Chairman thought it would be very injurious to the ratepayers of the Union if they rejected the lowest tender, which would have the effect of destroying competition, especially in such a dear commodity as the medicine supply.

Mr. M'Mahon observed that Mr. Hunt supplied the union with medicine during the past year, and none of the medical gentlemen found any fault with it, he thought they might just as well accept his tender this year also.

Ultimately, Messrs. Hunt's tender was accepted (pending the appointment of two securities which were omitted in the form), but the medicine was to be subject to analysis, and, in the event of its not being of the proper quality, the officers of the union were to purchase the best and charge the contractor with the increased expenditure (if any).

CLONMEL DISTRICT LUNATIC ASYLUM.

At the special meeting of the Governors, Dr. Flynn laid before the Board the following letter, resigning, through ill health, his official appointment as Resident Medical Superintendent :—

The following minute was unanimously adopted, several gentlemen expressing their sincere regret that ill health should have compelled the retirement of so faithful and zealous an officer as Dr. Flynn had proved himself to be :—

"The Board of Governors of the Clonmel District Lunatic Asylum, having received from Dr. Flynn a document announcing his determination to place his resignation in the hands of the Lord Lieutenant, we cannot allow his resignation to go forward without placing on record our unanimous opinion of the long and meritorious services of Dr. Flynn, extending over twenty-nine years, during which time his close attention to business, his unvaried humanity and skill in the management of the unfortunate class placed under his care, has at all times deservedly merited our most cordial approval. We most sincerely regret that Dr. Flynn's state of health has rendered his resignation advisable; and we wish now to convey to Dr. Flynn our most earnest and affectionate wish for the restoration of his health and his future happiness in his well-earned and honoured retirement.

"Charles Bianconi."

BELFAST BRANCH OF THE ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

On Wednesday, the usual quarterly meeting was held here of the committee of this local branch of the above most excellent and useful society, when the chair was filled by Professor Cuming, M.D., the other members present being Dr. Filson, M.D., Portaferry; Dr. Whitaker, M.D.; and Dr. Stewart, M.D., honorary secretary. The report was made that Dr. Brown, R.N., Mayor of Belfast, had attended as a deputation at the recently held annual meeting of the society at large in Dublin, which proved to be a very large and influential one, and at which, according to the official statements that were made, the affairs of the society appeared to be prospering, and that a steady increase of supporters was on its subscription roll. The several grants recommended to be given to the society's recipients of this branch were all freely made by the parent body, and have since been duly received by the respective applicants, each being deeply grateful for an assistance always in time and acceptable, however small in amount. The meeting on Wednesday had under discussion a subject which has been already frequently before it —namely, the large number comparatively of the Profession, both in town and in the country districts, who lend a deaf ear to the earnest calls made upon them to give their countenance and support to a society whose objects are so purely beneficent and so deserving of being maintained in vigorous operation, but which they cannot be expected to be when so many "shut up their bowels of compassion" from those of all others requiring their warmest aid. It was hoped, however, that this apathy would give way to a kindlier and more generous line of action—one which would redound so much to to the credit of all parties, and bring joy and gladness to not a few whose poverty was their misfortune, and not their fault. Some routine business having been disposed of, the chair was vacated, and the meeting adjourned.

Correspondence.

THE GUINEA FEE.

TO THE EDITOR OF THE IRISH MEDICAL ASSOCIATION JOURNAL.

Sir,—We believe most of the heads of our Profession, together with those who are anxious to uphold their rights, insist upon the value of the old English guinea in payment of fees. We have frequently heard it discussed whether the acceptance of a sovereign would not do equally well since the guinea coin has become extinct, but the majority ruled that the extra shilling was essential. Now we believe it is not generally known that when the guinea was originally coined it was intended to make it value for a current twenty-shilling piece, but from an error the value of the gold was increased. We understand in the time of Sir Isaac Newton the true value of the coin was twenty shillings and eightpence, and it was in his time the Crown proclaimed the value of twenty-one shillings. Of course we all remember the name guinea was applied because the coin was made from gold that came from the Guinea Coast. The first notice of this was in 1649, during the Commonwealth, but not until the days of Charles II. was the name really given. We hold, then, since the coin was originally intended to circulate for twenty shillings, and that a costly error was made, that the members of our Profession should be satisfied with the sovereign. We are the last to deprive our brethren of their rights, but this is one only of usage, and considering the coin was a costly error, and is now entirely superseded by a more useful one, we ought to feel satisfied with it and prove ourselves above associating the paltry shilling with the compact fee in the form of a twenty-shilling piece.

A Physician.

HEALTH OF DUBLIN.

In the Dublin Registration District, the births registered during the week ending July 23rd, amounted to 165. The average number in the corresponding week of the years 1864 to 1869 inclusive, was 173.

The deaths registered during the week were 118. The average number in the corresponding week of the previous six years was 109.

Seven deaths were caused by fever, viz. :—1 by typhus, and 3 each by typhoid or enteric and simple continued fever.

Scarlet fever proved fatal in 4 instances, and measles in 1.

Four deaths resulted from croup.

Eleven deaths were ascribed to bronchitis, and 2 to pneumonia or inflammation of the lungs.

Three deaths were referred to apoplexy, and 5 to paralysis.

Nine deaths were caused by heart disease, and 1 by aneurism.

One death was ascribed to nephria, or Bright's disease, and 1 to "urinary disease."

Phthisis or pulmonary consumption caused 20 deaths, mesenteric disease 2, and hydrocephalus, or water on the brain 3.

Five persons died from cancer.

Three deaths were the result of accidental causes, and 1 was suicidal.

Of the deaths registered during the week, thirty-two were under 5 years of age, and thirty-one were 60 years and upwards.

In the Dublin Registration District, the births registered during the week ending July 30th, amounted to 148. The average number in the corresponding week of the years 1864 to 1869 inclusive, was 157.

The deaths registered during the week were 114. The average number in the corresponding week of the previous six years was 132.

Seven deaths resulted from fever, viz :—4 from typhus, 2 from typhoid or enteric, and 1 from simple continued fever.

Scarlet fever proved fatal in 4 instances.

Four deaths were referred to diarrhœa.

Bronchitis caused 5 deaths, and pneumonia or inflammation of the lungs 2.

Three deaths were referred to liver disease, 1 to kidney disease, and 1 to nephria, or Bright's disease.

Seven deaths were ascribed to heart disease, and 1 to aneurism.

Twenty-four deaths were caused by phthisis or pulmonary consumption, 4 by mesenteric disease, 1 by hydrocephalus or water on the brain, and 3 by scrofula.

Four deaths were referred to cancer.

Thirty deaths occurred in persons 5 years of age, and 19 in persons who were aged 60 years and upwards.

THE LUCAN INSTITUTION FOR IDIOTS NEAR DUBLIN.

The Managing Committee have submitted to the Council a Report which states that there were 25 children in the Institution viz. :—14 Boys and 11 Girls—of these 9 are Free ; a portion of the cost of care and maintenance, varying from £2 10s. to £15 a-year is paid by the relatives of 9 others, and the entire by those of the remainder. The numbers were increased on the 1st of August, when an election was held for the admission of eight more—four to be free, and four partially paying.

In the Asylum there are at present 86 patients whose comfort has been greatly increased by the supply of new furniture and the improvements effected in the sanitary arrangements of the house.

In their last Report the Committee stated the circumstances that had arisen rendering it impossible to carry on the Institution and Asylum in the Lucan premises. Since then they have received offers of several places, one of which seemed to them so suitable that they called a special meeting of the Council to consider it, when it was agreed to accept the offer.

These premises consist of the House and Demesne occupied by the late Lord Donoughmore, at Palmerston, within five miles of the General Post Office. There are two houses and 47 acres of land enclosed on three sides by a high and substantial wall, and having free access to abundant supplies of water. The mansion-house will afford accommodation which could not be surpassed in excellence and convenience for the Lunatic patients, and the other will supply the wants of the Institution for Idiot till a new building can be erected.

A Committee that has been in existence for some time for the establishment of an Asylum for Epileptic Patients, having made application to have a ward opened for the reception of such patients in connection with the Institution, on the plea that the two conditions, Idiocy and Epilepsy, are very closely associated, your Committee have agreed to do so. It has been arranged that the funds should be kept perfectly distinct, and that the Epileptics should only have the benefit of the money collected for their own support, and that none should be admitted till a sufficiently large sum had been obtained to cover the cost of their care and maintenance.

We observe with very great satisfaction, that Mr. Justice Keogh has considered the evidence given by Dr. Alton of Tralee, in a recent trial worthy of a very warm eulogism. Such a tribute from one of Her Majesty's Judges, is a mark of approval as worthy of respect as it is unfortunately unwonted.

His Lordship said he seldom met with a gentleman who had power of conveying in more explicit or intelligible language the injuries received, showing how thoroughly he understood the nature of the case. He had given his evidence so that anyone of common sense could understand it.

Mr. Coffey, Q.C., replied for the defence of the four doctors, and paid a tribute to Dr. Alton for the lucid manner in which he had detailed his evidence. He said he should follow his lordship in congratulating the county on possessing such a man as Dr. Alton.

His Lordship in charging the jury said, he should congratulate them on having in this county one of the best specimens of clear speaking intelligent doctors he had ever met. He was a credit to the county. His Lordship was particularly struck with the abscence of useless technicalities in the evidence of Dr. Alton. He did not even use a classic quotation (laughter). Speaking of the fracture he said simply the blade bone. Why if he wished he could convert it into a string of words which you could not understand, and possibly himself.

IMPORTANT PROSECUTION UNDER THE CONTAGIOUS DISEASES ACTS.

At the Plymouth Police Court, on Friday, Mrs. E. M. King, and Mr. Daniel Cooper, Secretary to the London Rescue Society, who are at present residing at Devonport for the professed purpose of opposing the Contagious Diseases Acts on behalf of the Anti-Contagious Diseases Acts Association, were summoned for resisting those members of the Metropolitan Police who are specially appointed to work the Acts in this district applying to the Royal Albert Hospital, at Devonport, in the execution of their duty, and also for inciting certain women to resist the police. At present there are four summonses against Mrs. King, and one against Mr. Cooper, but it was stated by the Admiralty solicitor, Mr. E. W. Eastlake, that there are many others to be brought forward. So far as the case went, the facts appeared to be that Mrs. King and Mr. Cooper are in the habit of daily visiting a notorious street in Plymouth, occupied chiefly by women of bad character, for the purpose of inducing the women coming under the Acts not to submit to their provisions. In the case in question against Mrs. King, partly heard on Friday, a prostitute named Eliza Binney, who had purposely evaded the Acts for some time past by leaving the neighbourhood when served with a notice to attend at the hospital, and who had just returned, was being taken by the police to the hospital. On her way she was met in the public streets by Mrs. King and Mr. Cooper, both of whom directly advised her not to go unless taken by force. The police ordered them not to interfere, but Mrs. King, it was alleged in evidence, endeavoured to forcibly detain the woman by placing her arms round her waist, and pulling her away from the officers. The woman, who submitted quietly when first apprehended, now resisted so much that the police were obliged to use violence, and at last got a cab to convey her to the hospital, where, after being kept until the following day, she was seen by the house surgeon, and, at her own request, also by three private medical men, and discharged within an hour afterwards, there being no reason for her detention. The solicitor, on behalf of the Admiralty, said that the opposition of these people had become of such a serious character in the working of the Acts that he had been positively instructed to press in case of conviction against Mrs. King for the infliction of imprisonment without the option of a fine. The case for the prosecution in regard to the first charge against Mrs. King was closed on Friday. The address for the defence made by the solicitor on the opposite side raised the technical point that inasmuch as no evidence had been given that the woman had been served with a certificate requiring her attendance at the hospital, and inasmuch as there was no evidence that the magistrates had issued an order for her to attend—the Acts rendering it necessary that both these points shall be observed—the police had no right to apprehend her, and therefore she was not in lawful custody. The case was adjourned.

On Tuesday the hearing of the case was resumed. The evidence for the defence was completed, four witnesses having been called, whose testimony was directly opposed to that of the constables called for the prosecution. There were four summonses against Mrs. King and one against Mr. Cooper. The Bench, however, declined to give their decision in this case until the others were heard. The prosecution then preferred a second charge against Mrs. King for inciting a woman, whom the police were taking to the Royal Albert Hospital, at Devonport, to resist the police, and also a charge against Mr. Cooper for inciting the same woman to resist. The other two summonses were not gone into. It was contended for the defence that there was positively no resistance or incitement to resist, but that the only object in view on the part of Mrs. King and Mr. Cooper at the time in question was to raise the legal point as to whether the police, under the circumstances, were justified in apprehending the woman and taking her to the hospital. Several law points were raised in regard to the working of the Acts which will probably be settled in another court. The Bench fined Mrs. King and Mr. Cooper £5 and costs each. Notice of appeal was given.

MEAT PRESERVATION.

The first public sale by auction of colonial preserved meats recently took place at the stores of Messrs. Goldsborough and Co. The lots offered were 2,000 packages of meat, each package or case containing twelve 6lb. tins, the production of the Echuca Meat Preserving Company. This company, it may not be out of place to mention, says the *Melbourne Daily Telegraph*, has only been established a few months, by local enterprise, and with a nominal capital of £10,000. Since commencing meat-preserving operations, the company have used over 80,000 sheep and 200 head of cattle. Messrs. Goldsborough and Company introduced their first sale with a luncheon, and no meat except that of the Echuca Company found a place in the bill of fare. This consisted of kidney soup, spiced beef, boiled mutton and caper sauce, sheep's tongues and tomato sauce, Irish stew, and boiled beef and carrots. The cold meats, as turned out of the tins, were sweet and nutritious. The contents, prepared without bone, came out in compact masses, surrounded and permeated with gelatine. The crucial test, the eating of it, proved to be in every way equal to fresh meat newly cooked.

Compulsory Retirement.—A correspondent of the *Bombay Gazette* says that he has received by the mail, from a very authentic source, information that the Duke of Argyll has positively and peremptorily declined to offer any inducement to the senior members of the Medical Department of India to retire, and that he intends to carry out compulsory retirement at fifty years of age, on the promulgation of the Medical Warrant, which is shortly expected, authorising the amalgamation of the Indian with the British Medical Service.

The Army Medical Department.—The *United Service Gazette* says that it is confidently rumoured that the scheme for the unification of the Army Medical Department has been abandoned.

Original Communications.

A NEW CAUSE OF VENEREAL CONTAMINATION — TESTED BY PRACTICAL OBSERVATIONS AND INOCULATIONS FROM A HITHERTO UNRECOGNISED SOURCE — INOCULATION AS A MODE OF TREATMENT.

By Mr. Morgan, F.R.C.S.I.,

Professor of Surgical and Descriptive Anatomy, R.C.S.I.
Surgeon to Mercer's and the Westmoreland Lock Hospitals.

Much has yet to be done in reconciling the various differences of opinion which still exist between surgeons with regard to the venereal disease, many of whom have paid special attention to the subject. Thus, some will see the clearest evidences of the duality of the venereal poison, when examining the subject from one point of view; others will be equally positive of the contrary theory, and that, no matter what may be the form of the primary lesion, the ultimate effects on the system will be much the same; others, again, will see proofs of the existence of several forms of sore and infecting poison, each followed, as Carmichael supposed, by special constitutional evidences. Climacteric influences, diatheses, the effects of certain treatments, &c., modes of life, have all been looked to as explanatory of the various modifications of the primary and constitutional lesions that are so often seen; and each observer is apt to view the question through the jaundiced spectacles of preconception and of the particular school in which he had been trained. Though so much has been written on the subject, still the difference of opinion is most remarkable. It must be assumed that the Parliamentary Commission of Inquiry held during the last few years was the most complete investigation into the subject that could be obtained. Witnesses and experts were examined from different parts of the country and from abroad, and yet the most serious difference of opinion existed as to the nature and effects of the venereal poison, and as to the characteristics of certain forms of contagion; some holding to the dual theory of an infecting and non-infecting form of primary sore, and others expressing themselves as equally convinced of the contrary.

The Committee appointed by the Government, report that—"It is declared in evidence by twenty-nine experienced witnesses that sores both soft and hard may be followed by every variety of syphilitic eruption."

Some of these witnesses stated their views so strongly that they may well demand careful consideration. Thus—

Mr. Syme, whose opinion, from his well-known character as a practical surgeon, must be regarded as having been most authoritative and valuable, stated as follows, so shortly ago as April 7th, 1865:—

"Mr. Spencer Smith.—Judging from the view which you take of the disease and its pathology, and the treatment you adopt, I conclude that you rather incline to the opinion that the whole subject has been rather over-elaborated of late years?—*A.* Most thoroughly.

"Chairman.—Is there any further remark that you desire to make to the committee upon this subject?—*A.* I think that the refinements and the division of the local sores, and the varieties of them, and the modified administration of mercury for their cure, have done an infinite deal of mischief.

"With your large experience of venereal diseases, you must have seen every variety of sore. Can you readily distinguish sores at first sight during their early stages, supposing them to be divided into sores which affect the constitution and sores which do not, or hard and soft sores?—*A.* My experience does not lead me to divide them in that way. I believe that the variety of appearances in sores depends, not upon varieties of poison, but upon varieties in the constitution of individuals; the constitution, the habits, and the mode of life.

"You do not, I think, acknowledge the duality of the poison. You think that different sores are produced by the same poison?—*A.* I do."

Mr. Syme here, no doubt, alludes to the disease in males, and attests to the opinion formed by his "large experience" with them.

Mr. Lane, however, with twenty years' special experience at the Lock Hospital, London, gives his opinion as follows, April 11th, 1865:—

"Chairman.—How many years have you been connected with the Lock Hospital?—*A.* About twenty years.

"As acting surgeon, or consulting surgeon, or both?—*A.* As assistant surgeon for about 10 years, and acting surgeon or full surgeon for about 10 years. For the last 4 or 5 years I have been consulting surgeon.

"During that time you have had large opportunities of seeing the venereal disease in all its forms?—*A.* Certainly.

"I need scarcely ask you whether you recognise the constitutional disease known as syphilis?—*A.* I do.

"Do you recognise the two forms of the primary sore marked by the soft and the hard characters?—*A.* Yes, I recognise those. I should say that the soft chancre is the proper type of the syphilitic sore, and that the hard chancre, the phagedenic sore, and sloughing sore, are deviations from the soft chancre, that being the proper type of the venereal sore. I would add that I consider the primary sore a local affection, and that the constitutional disease depends upon the continual absorption of the poisonous matter of the original sore.

"I understand, from what you have already stated, that the type of the disease is the soft sore; but may I say that you are an opponent to the duality of venereal poisons?—*A.* Yes, I am an opponent to that. I consider there is but one poison."

Mr., now Sir W. Ferguson, very distinctly doubts the duality of the disease, applying the term syphilis to all sores, April 4, 1865:—

"Has it happened to you to have seen a secondary eruption arising from a soft sore?—*A.* Yes; I have seen it frequently.

"Would you treat that secondary eruption arising from the soft sore as you would treat the secondary eruption arising from a hard sore?—*A.* Yes, pretty much the same.

"Do you admit the distinction between non-infecting sores and infecting sores, meaning constitutionally infecting; that there is a sore that will not go further than just affect the glands of the groin, and another sore from which you will have constitutional symptoms?—*A.* No; I think that you see the constitutional symptoms from the soft sore as readily as from the hard. I look upon the hard as the more severe form of the disease. I have seen secondary symptoms come on after a soft sore."

Mr. Busk, surgeon to the *Dreadnought;* Mr. Acton; Mr. J. P. Lane; Mr. Nelson, Melville Hospital; Surgeon Major Stuart; Mr. Longmore; Mr. Cutler; Mr. Coote; Mr. Erichsen, and others, did not recognise the dualist theory.

On the Continent, authorities are not agreed. In America they are not either. Thus, Bumstead (following the French School) urges the dualist theory; yet Gross, in his masterly work on surgery, states as his conviction:—"My observations would lead me to infer that while there are really two varieties of chancre, the indurated and the soft, they do not by any means possess the properties which he (Ricord) ascribes to them. So far from giving my adhesion to such a doctrine, I have had the most unequivocal evidence in numerous instances of the infecting properties of the soft chancre; indeed, I am satisfied that some of the very worst cases of secondary and tertiary syphilis, that I have been called on to treat, have been cases of this description, originating generally in very small sores upon the head of the penis or prepuce, perfectly soft in their consistence, very superficial, manifesting no disposition to spread, and soon completely disappearing."

It is matter of daily observation at the Westmoreland Hospital that infection signs follow sooner or later almost every case of primary sore; but the series of cases I have detailed, when alluding to inoculable vaginal secretions, will prove abundantly that the usually believed infecting type of sore, or glandular enlargements, is a rarity in these women, who must be accepted as the true specimens of the disease in Dublin.

I have received the most recent information on this question from the Government Lock Hospital, Aldershot. June 29th, 1870, the surgeon states:—

"Undoubtedly, many patients are admitted suffering from general syphilis, in whom soft sores have only been detected, with or without suppurating bubo. That even while in hospital with inoculating sores only, secondary manifestations do occasionally occur."

From the Government Lock Hospital, Cork, out of 324 cases the surgeon states:—

"Amongst the sores I have not met with more than two or three which could be considered in any way indurated—almost all were superficial—secreting pus or mucus, without any marginal thickening, elevation, or induration; in fact, they all had the character of the soft sore—the indurated chancre in the female *being very rarely met with here.*

"Of this I am positive that I have had here several cases of what is usually known as the true Hunterian chancre, under my care in the male; and, as I have stated before, I have not had one well-marked case of the same form of chancre in the female. My experience is that the indurated chancre is not invariably followed by rash, sore throat, &c.; it is usually so followed, but not so frequently as generally supposed."

From the Lock Hospital, London, July 4th, the surgeon states:—

"Severe secondary symptoms have also frequently occurred after soft sores. A considerable number of soft sores are also followed by symptoms; there is not much difference in their severity, whether following a hard or a soft sore."

It is remarkable that the description of the primary sores at the Lock Hospital, Cork, Aldershot, London, and here, agree so exactly—yet in all these places they must be considered as, at least, the chief sources of the disease as communicated to the male population.

A careful examination of the subject, with the large number of 1,582 cases under observation in the Westmoreland Hospital during the past two years, have satisfied me that the sore now prevalent amongst females but very little resembles the usually accepted type of the infecting sore, while it is most certainly followed by constitutional signs. I refer, of course, to the disease as it occurs in Dublin; and as I see it pursue its course in the wards of the hospital, representing the contagion source of the disease in this city. Out of all the cases under my treatment during the last eight months, but two represented the characterising features of the infecting sore so defined. In these two cases nothing could be better marked than the figure of the sore—its non-purulent aspect, indurated base, smooth surface, comparative insensibility, and pleiad of indurated glands. Yet the constitutional signs in these cases were by no means severe, or at all as marked as in, I might say, all the other cases of primary sores, where there was not the slightest evidence of induration, or any of the usually described essentials of this type of sore; in fact, the two cases present nothing very unusual in the following summary of their history:—

No. 661.—A comely girl of eighteen had been on the town seven months only, and had never been before diseased. She first observed a sore a fortnight before; on admission, Oct. 11, 1869, a perfectly marked hard or Hunterian sore, about the size of a fourpenny-piece, existed on the labium; there was no evidence whatever of a previous sore, and the inguinal glands of the same side were somewhat dense. The sore gradually healed in three weeks by local appliances; but in one week before it did so, a scattered papular rash appeared over the body; a smart iritis also

ARTIFICIAL CONTAGIOUS SORES

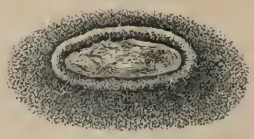
PRODUCED BY INOCULATION.

By Mr. MORGAN, F.R.C.S.I., &c.,

SURGEON TO MERCER'S AND THE WESTMORELAND LOCK HOSPITAL, DUBLIN.

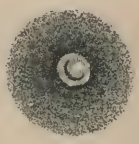
PLATE I.

Series 1.
Sore produced by inoculation from another sore, the product of spontaneous inoculation by apposition with the opening of a bubo, on a patient not having at the time any primary sore, but who soon developed constitutional signs.

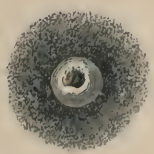


Series 2.
Sore produced by inoculation with the vaginal discharge of Series No. 1 after having been two months under observation in hospital.

Series 3.
Sore produced by inoculation from another sore, the produce of inoculation with the patient's own vaginal discharge, when sixty-three days in hospital.



Series 4.
Pustule produced from inoculation with a vaginal discharge twenty-four hours after introduction.



Series 5.
Pustule produced by inoculation from a sore the product of a sore inoculated from a vaginal discharge.

Series 6.
Pustule produced by inoculation from the patient's own vaginal discharge as seen seven days after inoculation. Pustule now burst.

developed itself, and she had some flying nocturnal pains and alopecia.

The treatment consisted in 10 gr. calomel suppositories used per vaginam every night, or every second night, and the patient was discharged cured.

The dense cicatrix of the original sore still existed.

In this case the iritis was very amenable to treatment, and, indeed, so were all the constitutional signs. The patient had been in good condition, and was well off as to diet, lodging, &c.

No. 898.—A very well conditioned girl of twenty; had been about two years living irregularly; accustomed to a luxurious and dissipated life; first felt a sore two months before admission, February 10th, 1870. As in the former case there was a well marked typical sore on the labium—now nearly healed—and there were some coppery papules over the body, particularly on the face and chin, but the general condition was very good. So mild were the symptoms that the patient would not remain any length of time under treatment, and left hospital.

Neither of these cases have returned to hospital, which make it pretty certain they suffered no farther symptoms.

It is remarkable that though these were the sole representatives of the typical infecting sore, they escaped with very mild manifestations indeed of the constitutional influence; while in numerous other instances, tabulated in the subjoined lists, it will be seen that though the apparent primary sore was of the soft, or so-called non-infecting type, yet that constitutional signs almost invariably appeared :—

TABLE No. I.

List of Patients who have been Last Admitted with Primary Sores, Diseased now for the First Time.

Nature of the Primary Sore.	Followed by				
	Papular Rash.	Patches.	Pains.	Iritis.	
One soft, not inoculated	Yes	—	—	Yes	
One large soft, do.	Yes	—	—	—	Produced a dead child.
Do. do.	Yes	—	Yes	—	Produced a living child.
Soft sore	Yes	Yes	Yes	—	All but suppurating bubo and sore [throat.
Sloughing sores	—	—	—	—	No constitutional signs or bubo.
Do.	Yes	Yes	—	—	
Chronic sore	—	—	—	—	
Do.	Papulo-squamous	—	—	—	
Do.	—	Yes	—	—	With anal fissures.
Do.	—	—	—	—	
Large soft sore at fourchette ...	—	—	—	—	Nothing observed during thirty-three days succeeding.
Do. do. ...	—	—	—	—	Has been since admitted with rupious ulcerations.
Slight sore do. ...	—	Immense patchy vegetations	—	—	No other signs.
Ulcer of uterus	—	—	—	—	No other signs.
Do.	Yes	—	Yes	—	
Several soft sores, auto-inoculated three times	Yes	—	Yes	—	Was thoroughly cachectic.
Do. auto-inoculated...	Yes	—	—	—	
Do. do. ...	Yes	Yes	—	—	
Do. do. ...	—	Yes	—	—	
Do. do., twice	—	—	—	—	Got warty vegetations at urethra.
Do. do. ...	Yes	—	—	Yes	Extreme alopecia; suppurating bubo.
One sore do. ...	—	—	Yes	—	
Do. not inoculated...	Yes	Yes	Yes	Yes	
Do. do. ...	Yes	—	—	—	Suppurating bubo and roseola.
One large do. ...	Yes	Yes	Yes	—	Suppurating bubo.
Do. do. ...	Yes	—	Yes	—	Suppurating bubo.
Do. do. ...	Yes	Yes	—	—	Produced a dead child and roseola.
Do. do. ...	—	—	Yes	—	Extreme alopecia.
Several soft do. ...	Yes	—	—	—	Cachexia.
Do. do. ...	Yes	Yes	—	—	
Do. do. ...	Yes	Yes	—	Yes	
Do. do. ...	Yes	Yes	—	—	Produced a dead child.
Do. do. ...	Yes	—	—	—	And gummata.

A consideration of this tabulation shows that, though seven of these cases had inoculable sores, one only failed to show constitutional signs of a decided character; four others had suppurating buboes, yet also subsequently showed infection signs, while numerous other instances, witnessed by their subsequent manifestations such as rash-iritis, patches, pains, &c., the potent influence of the constitutional poison, of which the source appeared to be a primary sore, devoid of induration, or other character usually ascribed to the infecting type.

b

TABLE No. II.

TABLE OF THE LAST NINETEEN PATIENTS NEVER BEFORE DISEASED, ADMITTED FOR THE FIRST TIME, WHERE THE PRIMARY SORE WAS EITHER HEALED OR HAD NOT BEEN RECOGNISED BY THE PATIENT.

Mucous patches only.	Papular.	Pains.	Iritis.	
Three cases	Yes	Yes	Yes	With discharge.
Six „	Yes	—	—	One produced a dead child with discharge.
Three „	Yes	Yes	—	One with patches of the throat with discharge.
Two „	—	Yes	—	With discharge.
Three „	Yes	Yes	—	With discharge.
Two „	—	—	—	With discharge.

The second tabulation shows the remarkable sequence of rash and other signs after mucous patches. Had the primary been a typically infecting sore, it could hardly have escaped notice, on account of its density and long persistence, as well as from the tumid state of the inguinal glands, which retain their induration so long.

From observation of the disease in a number of cases of both sexes, it seemed to me necessary that some source of origin existed for the propagation of primary sores than that usually recognised. This I was particularly interested in from seeing the disease apparently communicated to males from females who seemed not affected by any sore, and that the form of the affection in such instances was that of the soft or contagious sore. I consequently undertook an investigation into the origin and propagation of this prevailing form of sore, found both in the female and male, the results of which go to prove that the soft or chancroid, and easily inoculable sore, is capable of being produced from a vaginal discharge or (in the ordinary acceptation of the term) from a gonorrhœa in a patient, where constitutional taint exists, and this taint may be as yet occult, or may have shown itself, and be apparently cured.

I have tested this by a tolerably extensive series of inoculations, and as yet have not been able, with one exception, to produce a characteristic pustule and sore, where evidence of constitutional infection was wanting; but where such was present I have found little or no difficulty —indeed, the vaginal discharge in a purulent, or even muco-purulent form, furnishes a more potently inoculable source often than the sore itself. I here allude to the ordinary inoculable sore, which I have often inoculated both in male and female, and yet seen constitutional signs follow in women almost invariably, and in men not unfrequently.

In order to avoid, as far as possible, any sources of error, I selected cases for some time confined to hospital, and I have tested by inoculation the various conditions of the system as furnished by the vaginal secretion, be it purulent or muco-purulent: thus, in the first series, I inoculated from the artificial product of a spontaneously inoculated bubo, and produced, as usual, a chancroid, or soft sore, on the patient's person; from the vaginal secretion of the same patient, who never had a sore that I could detect, and who believed herself never to have had one, I inoculated a case in another part of the hospital, thus avoiding the possibility of confusion, and produced a most characteristic pustule and sore; this produced its like on the patient's own body, by the accidental inoculation of a pimple.

In various other cases I have inoculated in like manner, invariably producing the regular contagious sore. My inoculations were always performed on subjects already under the syphilitic influence; I cannot therefore distinctly state that in a virgin subject the result would be a chancroid, but it may very reasonably be so concluded. It goes far to explain the occurrence of constitutional signs when we consider that the initial sore may have originated from the vaginal discharge of a constitutionally infected patient when grafted on another also infected, and thus be communicated to a person hitherto unaffected; and although its appearance would be that of the soft, so-called uninfecting sore, yet, from its doubly-poisonous mode of generation, it can hardly be supposed its infecting properties would not be most intense.

It is remarkable that the vaginal discharge retains the property of producing a sore by inoculation after the healing of the primary, as will be seen by referring to the accompanying remarkable cases of inoculation while in hospital and under surveillance:—

All observers agree that constitutional syphilis can be communicated from various secretions, such as from mucous patches, of the mouth, vulva, breast, &c., and from the blood, &c.; yet, by direct experiment, it can be shown that the "soft," or usual form of venereal sore, can be communicated by inoculation from the vaginal discharge of patients intensely syphilitic, and that this sore, when reproduced on other patients, also intensely syphilitic, still shows itself as a soft sore. There remains, I think, no difficulty in presuming that this product, which may have been reproduced through many tainted generations, is thoroughly infecting in its properties, and from its mode of reproduction should be more intense in its results than the justly feared offspring of mucous patches or other secondary lesions.

I have selected the following cases to illustrate the propagative power of vaginal discharge, and also to prove the beneficial effects of the inoculation treatment, which has of late attracted so much attention:—

SERIES No. 1.—*Inoculation with vaginal muco-purulent discharge from a patient not suffering from a sore, performed on a child eight years old, suffering from vulval condylomata —Production of a typical soft sore on the abdomen—Propagation of chancroids from this sore.*

CASE No. 1,024—Ward 2—aged eighteen, a very well conditioned girl, having only left her home in the country six months before, was admitted on April 2, 1870, suffering from a very large suppurating bubo of the left groin, rather below Poupart's ligament, but having no sore, and not being aware of ever having suffered from one. I opened the bubo, which was painful, and contained a large quantity of pus. After a fortnight a speculum examination was made, but no sore discovered; there was some vaginal discharge of a semi-purulent character.

May 6th.—A sore was observed forming on the abdomen opposite to the orifice of the bubo, which was still unclosed; this sore in a few days assumed all the characteristics of a soft sore, or chancroid. By speculum examination, repeated on ten different occasions, no sore could still be discovered.

On the 19th of May, 1870, I inoculated the right side of the abdomen from the naturally auto-inoculated sore,

caused by the irritation of the discharge from the bubo; this formed a most characteristic pustule with depressed centre; it then ulcerated, and finally presented the aspect shown in the drawing taken by Mr. Mackay on June 14th. All the characters of a chancroid were well seen, with the peculiar edge, irregular surface, and copious discharge.

Thus far the history is clear. First—Of discharge from a bubo causing a sore by apposition. Second—Of an inoculable sore procured from this source. Third—Of the transmission of this sore, the second generation of a suppurating bubo to another person already syphilized, producing a characteristic pustule and sore as the third generation.

The most interesting and startling point with regard to this case is, however, the inoculability of the vaginal discharge, which I proved thus:—

Having had the patient under my observation, and confined to hospital for exactly two months, and having satisfied myself by frequent and careful speculum examinations that there was no possibility of an intra-vaginal sore, and that but a very little muco-purulent discharge alone existed, on the 2nd of June I removed some of the vaginal secretion through a speculum, taking care that it did not even touch any external part, and I inoculated with it on the abdomen a girl eight years old, No. 1,140, suffering only from vulval condylomata, with a very clean and clear skin; this produced a most characteristic pustule; this became on the fifth day a perfectly formed ulcer.

The sequence of constitutional signs thus showed itself:—

On June 14th the sore caused by the bubo inoculation had quite healed, having existed about thirty-five days. Papulo-squamous rash now appeared on the arms, the chest, the thigh, and the loins; the hair commenced falling out, and a slight iritic attack showed itself. There was a general murkiness of skin, but the health improved; the second inoculated sore shows as yet but little inclination to heal.

The patient rapidly improved, and left hospital on July 4, 1870.

SERIES No. 2.—*True chancroid produced on an already infected patient from the vaginal discharge of a patient, who, though not at the time showing infection signs, shortly did so, while in the hospital.*

No. 1,118.—A girl, eight years of age, was admitted May 18th, Ward 8, suffering from condylomata of the vulva and anus; there was no rash whatever, but she had an ulceration of the arm of a gummatous character. The history of the case points to her having been infected by her sister, a married woman, who had been in the hospital under my care this year for very copious mucous patches of the mouth and labia. Her husband, to whom she had been married but a few months, I saw also; he was suffering from mucous patches of the mouth, and admitted having had a sore and suppurating bubo five months before his marriage.

This girl I inoculated on June 2nd with the vaginal secretion of the preceding No. 1,024, Series No. 1, taking it carefully by means of a speculum, as before mentioned. A most characteristic pustule and sore was produced, the appearance exactly representing a chancroid, or soft sore, as shown in the illustration.

There was no possibility of any accidental contact with a sore, as the part was carefully guarded by a watch-glass, and the progress of the inoculation till the formation of a perfect typical sore was most regular. The drawing was taken twelve days after the inoculation.

In order to test the specific nature of this inoculated sore, on June 13th I introduced some of the discharge from the surface on the point of a pin on the right side of the abdomen of Case 1,085, a woman suffering only from a primary sore, and procured a most characteristic pustule and sore. Still further to try the communicability of this artificial sore I tested the patient No. 1,000, suffering from intense syphilitic poisoning, a most abundant rash, and recently having had a suppurating bubo, producing chancroid sores.

It is evident that in these two instances the artificially produced inoculations were equally contagious; the one, Series No. 1, produced from the offspring of a suppurating bubo in the same person, and the other, Series No. 2, produced in another person from the vaginal muco-pus; and those sores could, of course, be reproduced indefinitely. Supposing that either of these or similar cases communicated a sore to a male, I cannot doubt but it would have every resemblance, as shown in the illustration, to a soft, or chancroid sore, so called; but I also cannot doubt it would be an infecting sore, having originated in the 1st series from the vaginal muco-pus only of a patient showing, subsequently, undoubted signs of infection; and in the 2nd series having a double contamination, first, from the source of origin, the vaginal muco-pus of an infected patient, and then of the already infected patient, on whom the poison was grafted, and, as in this instance, already suffering from constitutional evidences. Experiments go far thus simply to explain how it is that constitutional evidences have been seen to follow soft or chancroid sores.

The health of this girl rapidly improved, and the condyloma healed; the artificial chancroid inoculated a pimple in its neighbourhood, and lasted about one month. She was discharged perfectly cured July 21, 1870.

SERIES No. 3.—*Inoculation from the vaginal discharge of an intensely syphilized patient—produced on her own person sixty-three days after admission—Auto-reinoculation from this artificial sore—Indefinite power of this second product—Non-inoculabity of the primary sore—Suppurating bubo—Papular rash—Nocturnal pains and intense cachexia—Rapid improvement of the health by inoculation.*

In Series No. 2 the development of a contagious sore from inoculation with a vaginal discharge is sufficiently evident, where the vaginal secretion was inoculated on a different person. A more interesting and curious circumstance with regard to communicability is that of the formation of a contagious sore on the patient from her own vaginal discharge, and the capability of this sore, so produced, to give birth to a second, and this of being propagated indefinitely.

Patient No. 988, admitted March 21, 1870, aged hardly eighteen years, left home in the country about four months before her admission; during that time she got a severe inflammation, apparently of a strumous nature, from which she lost an eye. About three weeks previous to admission she observed a sore on the left labium—non-painful, pus-secreting, and equaling a florin in size, without the slightest induration; a painful bubo was formed in the left groin, which suppurated shortly after admission, and from which I produced a characteristic but feebly marked pustule and sore on the abdomen.

In four weeks after her admission a copious coppery roseolar and papular rash appeared; she became intensely cachectic, and racked with pains, had sweatings, and was thoroughly prostrated by the syphilitic poison.

She was treated up to this by tonics, good diet, iodide of potassium, and iron. The stomach became very irritable, and it was impossible to give any internal medicine—even a creasote mixture was intolerable.

I therefore used the cautious and careful inunction of ten grains of mercurial ointment every afternoon. Unde this treatment, after ten days, there was some improvement in the general symptoms.

On the 23rd of May (being sixty-three days from her admission), I had the patient, who was extremely weak and prostrate, carried to the table, and, on speculum examination, found a rather copious vaginal muco-purulent secretion. I removed some of this through the speculum,

and washed out and examined the vagina and uterine neck; there was not the slightest breach of surface, or even irritation. I inoculated the left side of the abdomen with this pus, and produced a very well-marked, but not large, characteristic pustule.

On May 28th, in order to test the inoculability of the primary sore, I collected from the surface a copious charge of pus, with which I inoculated the abdomen, but with a negative result.

On June 3rd, being ten days from the date of the inoculation from the vaginal discharge, I inoculated the right side of the abdomen from the artificially formed sore, and produced a more perfect and vigorous pustule than in the first instance. This I refreshed, on June 9, with her own vaginal discharge, producing a sore, from which I performed the following inoculations, amply proving the contagious property of this second transmitted product of a vaginal discharge on the patient's own person while suffering from intense syphilitic intoxication.

June 7th, being four days after the introduction of the second virus, I inoculated Case No. 1,075 with the pus from the second inoculation, having first allowed it to dry. Whether from this cause, or the early stage of the pustule, or some accidental mal-performance of the inoculation, it did not succeed satisfactorily, fading away in three days.

June 9th, I inoculated from her vaginal discharge Case 1,159, already syphilitic, but with ill-formed result, fading in three days.

June 10th, three days afterwards, inoculated a weak cachectic patient, No. 1,163, suffering from copious papular rash, and produced a characteristic, small, well-shaped, pus-secreting ulcer on the abdomen, the exact resemblance of the parent source.

June 11th, I inoculated with the same (having first allowed the pus to dry), No. 1,169, suffering both primary sore and copious spots, but possibly from this cause, did not succeed satisfactorily, the pustule being abortive.

June 12th, I inoculated with the same, Case No. 1,112, suffering from what may be termed a true typical sore on the right labium, without induration, but with somewhat indurated inguinal glands on the right side, with copious papular rash appearing at the same time. This inoculation was most successful—producing a pustule and marked chancroid; illustration of which is very perfect, as taken two days after the inoculation, showing the pustule and peculiar inflamed base.

This series shows the inoculability of a vaginal discharge on the *patient's self;* the re-inoculability of this artificial sore on the *patient's self;* the propagation of this sore to other patients suffering from syphilitic manifestations, as No. 1,112 and No. 1,163.

The improvement of this girl's health from the period of the inoculations was most remarkable. She is now, June 18th, almost without a symptom, though taking no medicine. Wine, stimulants, good diet, have been freely given, but no medicine.

On June 23rd, I again inoculated her from her own vaginal discharge, and produced by the 28th a regular characteristic pustule, being now three months after admission to hospital. On the same day I inoculated from the same source No. 1,060 with success, and No. 1,093 without success. Discharged perfectly cured August 1st, 1870.

During the last two years no more intense case of true primary syphilitic intoxication has been in the hospital, and, though contrary to received theory, she suffered from a very large suppurating bubo on the same side as the sore, which had not the slightest induration; it secreted pus freely, was painful, and extensive, having all the characters attributed to the soft non-infecting sore.

SERIES No. 4.—*Primary sore—Non-indurated—Roseolar and papular rash—No inguinal enlargements—Inoculation from a vaginal discharge—Formation of characteristic pustule—and soft sore—Cure of the constitutional signs.*

No. 1,075, a remarkably strong healthy-looking girl of twenty-one, and had been a domestic servant till within two months, was admitted April 27, 1870. Ward No. 2.

About one week previously she felt a sore at the fourchette. On examination, this is ragged, pus-secreting, and painful; there are no inguinal enlargements whatever, and there is some slight discharge; but the rent at the fourchette is too sore to allow the use of the speculum.

On May 26th, being thirty-six days since first observing the sore, roseolar blotches appeared on the body and face, and in a few days more some scattered papules also were seen; the throat became patchy and sore.

On May 31st, inoculated her with her own vaginal discharge, using the speculum to see that the vagina was free from any sore. The result was negative, but some redness and anger appeared at the site of the inoculation for the first two days.

On June 13, I inoculated her from Case No. 1,093, a strong very dark skinned girl, having no sore, but suffering from copious mucous patches, discharge, papular rash, and pains, and having had, with the primary, two months previously, a suppurating bubo; the extensive scar of which is very visible. This inoculation was a perfect success, the pustular stage, after twenty-four hours, is well shown by the drawing, taken at the expiration of this time, a perfect chancroid, as large as sixpences formed. The patient rapidly improved from the date of re-inoculation, and the rash completely disappeared. I did not think it necessary to test the inoculability of this artificial sore further, as the appearance was so perfectly marked.

On July 7, I inoculated this patient from vaginal discharge of Series No. 12, forming a perfect pustule and sore.

SERIES No. 5.—*Primary sore of the right labium—Non-indurated, but presenting the general appearances of an infecting sore—Tender and indurated inguinal glands on the same side—Copious papular rash evolving itself—Primary sore resisting inoculation—Inoculation from a vaginal discharge.*

Patient aged twenty-two, No. 1,112, married, has a healthy child living; her husband died of phthisis two years since; four months ago went on town, and first felt a sore one week before admission, on May 13, 1870. She is now in tolerably good general condition, and has a sore about the size of a fourpenny-piece on the labium, with non-indurated base, but having a clean surface, secreting but little pus, and resembling the general appearance of an infecting sore, minus induration, or even a parchment thickening; a slight enlargement could already be felt in the inguinal region, and the glands became rather dense.

May 16.—I inoculated from this sore when unirritated, but without success.

May 23.—Some murkiness is appearing about the face.

May 31.—Inoculated with gonorrhœal matter from a male patient, but without success.

June 3.—Inoculated from her own vaginal secretion, which is hardly a pus secretion, with negative result.

June 7.—Inoculated with vaginal muco-pus of a girl aged seventeen, No. 1,140—suffering from patches of the vulva, purpuric, and lichenous spots—with this I produced a characteristic, but not vigorous pustule, which faded and dried up by the 12th of June.

June 9.—Found a small ulcer of the uterus appearing, and inoculated from it, without result.

A papular rash was now showing itself on the face and limbs.

June 12.—I now inoculated from the second artificially produced pustule of 988, Series 3, being the grandchild, so to speak, of a vaginal discharge, and it produced, by the 16th, a well-marked pustule shown in the illustration—the angry base, depressed centre, and peculiar pustule is very typical indeed.

On June 16, I performed a most interesting experiment. A patient, No. 911, who had been for over three months in the laundry of the institution, and who had been nearly

two months under my care, in the hospital, previously (so that she was under observation and absolute restriction for more than five months) had no sore for over four months, and came under my care again, with papular rash, alopecia, and patchy ulceration of the throat. I made a vaginal examination, and found a muco-purulent discharge still existing; with this I inoculated the subject of this series on the opposite side of the abdomen, and produced a characteristic pustule and well-marked sore.

On June 27, I inoculated the patient from this vaginal discharge of the patient, forming Series No. 11, and produced a most characteristic pustule and chancroid.

There is no doubt but that this pustular sore, the offspring of the vaginal discharge of an intensely syphilitic woman, in another intensely syphilitic, was indefinitely transmissible, and that the former inoculation of June 16, as the grandchild of the infected patient, grafted on another equally intensely infected, was also indefinitely transmissible.

If either of these doubly distilled poisons were communicated to a healthy male, it is surely pretty certain that, though the appearance would be that of a soft sore, it would communicate the taint. Yet, what is here demonstrated experimentally and artificially, I have no doubt, does frequently occur, as I have often seen non-indurated sores and suppurating buboes, and inoculable sores, followed by constitutional signs in the female, and not very rarely in the male.

SERIES No. 6.—*Inflammation of the labia—Condylomata—Papular rash—Vaginal discharge—Disappearance of the rash.*

No. 1,060.—A strong girl, aged nineteen, about twelve months on the town, and never before diseased; was admitted April 22, 1870—Ward 2. She is about four months pregnant.

She had observed one month before a sore at the labium, which was not very painful. She has now inflamed and tumid labia, patchy sores, and elevated condylomata, and a papular rash making its appearance.

There is a large surface of elevated pale patchy sores between the labium and the thigh, and, on vaginal examination with the speculum, no sore or abrasion could be detected, but there was an appreciable amount of muco-purulent discharge.

On May 30, a sore was observed on the mons veneris, opposite to one of the ulcerated mucous patches on the thigh, having much the appearance of a soft sore; from it I inoculated the abdomen, and, on June 3, a small pustule formed; but by June 7 had died away.

June 7.—I inoculated the other side of the abdomen from her own vaginal secretion, which was then not very abundant; this formed a well-marked pustule with depressed centre and somewhat inflamed base—the drawing of which was taken on the 14th June—seven days after the inoculation. The next day this burst and gradually dried up, the small ulcer left by it healing up by the 20th. The entire stage of this sluggish, but not abortive, inoculation being thirteen days.

June 25.—I inoculated in two places, the abdomen with vaginal secretion, now hardly purulent, of 988, Series 3, three months after her admission, and produced most characteristic pustules and sores equalling a shilling in size.

The rash had quite disappeared by July 6; the mucous patches and labial tumefaction still partially existed.

(To be continued.)

SECONDARY HÆMORRHAGE,

OCCURRING ON THE EIGHTH, FIFTEENTH, AND TWENTIETH DAYS.

By JAMES DOBBIE, M.D.

MRS. L., æt. forty-one, was safely delivered of her eighth child, placenta came away entire, uterus contracted firmly, and the lady was making an excellent recovery, when, on the eighth day, apparently from over-exertion, she was suddenly seized with most alarming hæmorrhage. When I arrived I found the patient in a very prostrate condition, pale, anxious countenance, feeble pulse, cold extremities and bleeding most profusely. On pressing over the abdomen I found the uterus distended to the size of a child's head, and on making an examination the parts were found very relapsed and the os dilated to the size of a shilling. I removed the clots and applied firm pressure over the uterus, at the same time applying cold to the pubis, and administered liq. ergot every half-hour. Finding this did not succeed in stopping the bleeding, I plugged the vagina, retaining the plug in for several hours; on its removal I found the hæmorrhage had ceased, I continued the pressure over the uterus and also administered the ergot at longer intervals. The bleeding did not recur, and the lady made a good recovery.

Mrs. B., æt. thirty, was making an excellent recovery from her second confinement, and everything had gone on naturally and well, when, moving about on the fifteenth day, she suddenly alarmed her friends by falling down in a faint—on being removed to bed she was found deluged in blood. When I saw her she had considerably recovered, but was still very weak, and the bleeding still pretty profuse. I found the os slightly dilated, I applied cold to the parts, and kept up pressure over the uterus and administered ergot and acidulous drinks. The flooding recurred on three separate occasions, but ultimately ceased, and the lady made a good recovery. The hæmorrhage in this case appeared to have been induced by constipation.

Mrs. K., æt. twenty-eight, had made an excellent recovery from her second confinement, and everything had gone on naturally, when on the twentieth day she had a considerable hæmorrhage, but, with rest and similar treatment to the above, the patient recovered and did well. The cause of hæmorrhage in this last case appeared to have risen from the patient using too much exertion over the washing-tub, and from having suffered for three days from the irritation of toothache.

Hospital Reports.

ARMY HOSPITALS.

CASE OF SUDDEN DEATH IN TYPHOID FEVER.

By Assistant-Surgeon BOILEAU, M.B., 29th Regiment, Canada.

PRIVATE G.P., aged twenty-three, and having completed a service of seven years, was admitted into hospital on the third day of the fever. On the fourth I recorded an unusual weakness of the cardiac systole. He progressed most favourably until the thirteenth morning, having all the usual symptoms of the disease, which appeared to be of a mild but decided type. The only medicine administered was 10 grains of the bicarbonate of soda in 2 drachms of the tincture of gentian, which he took three times daily. On the day preceding his death, this medicine was omitted, and 10 grains of compound kino-powder substituted. From 8 to 10 ounces of wine, with 2 pints of beef-tea, were given to him daily.

Up to the moment that he expired, there was not a sign or symptom to warrant an unfavourable prognosis.

Fortunately, for my own satisfaction, I had given to the patient himself, and to his attendants, the most precise directions that not for any purpose whatever was he to sit up in bed, but that he was to remain in the recumbent position. Unfortunately this injunction was unheeded by the patient, who, while in the act of sitting up in bed about two o'clock in the afternoon, to take a drink, fell backwards and at once expired

I made a most careful *post-mortem* examination, and found nothing to account for death; the brain, lungs, heart,

liver, spleen, kidneys, being apparently healthy. In the right side of the heart. a fibrinous clot extended from auricle to ventricle, almost including the tricuspid orifice; the left side was almost empty. Peyer's glands were much congested, indurated, and raised above the level of the surrounding mucous membrane, but there was no appearance of ulceration. Stomach and colon healthy.

Such untoward events as these appear to be analogous to the many recorded cases of sudden and unaccountable death after labour. In most of them, no information of any practical worth has been obtained by an autopsy. Paralysis of the heart is supposed to be the cause of death, and this seems to be a rational explanation. I expressed this opinion at the time of the occurrence, but it was objected to on the ground that, if paralysis of the heart was the cause of death, then the cavities would have been found distended with blood. I am not aware, however, of this having been proved. Nearly every recorded death of this kind has occurred at the moment of some sudden exertion on the part of the invalid, some effort which withdrew the aid of gravity from the weakened heart's propelling power. Does it not appear to be a reasonable assumption, that the sudden anæmia of nervous centres, likely to be produced, would lead to paralysis of the heart —of a heart propelling blood of impaired quality and reduced in quantity, the blood of a patient thirteen days prostrated by typhoid poison?

The practical lesson to be learnt from such a case is the necessity of investigating the condition of the heart in fevers, and of impressing on patient and attendants the danger of any movements calculated to overtax it, when its condition of exhaustion is evidenced by our examination.

Transactions of Societies.

BRITISH MEDICAL ASSOCIATION.

The annual meeting has been held at Newcastle-on-Tyne during the past week. On Tuesday, the first day of the proceedings, the Council met in the morning and transacted business. In the evening the first general meeting was held, when Dr. Chadwick, retiring President, handed over his office to Dr. Charlton, President-elect.

Dr. Chadwick, in retiring, reviewed the work of the year in an able address, closing in the following words:—"I must not forget that my chief duty here is to introduce you to my excellent successor. (Loud applause.) In Newcastle it would be folly to attempt his praise, even though I speak with the authority of more than thirty years' acquaintance. (Applause.) He has made for himself a position here which warrants this great Association accepting him as their President. He belongs to a class of medical practitioners well deserving consideration —a class doing much in the unostentatious exercise of their medical duties to maintain the dignity of the profession, and secure the esteem of every class of the community. (Loud applause.) Dr. Charlton is an honour to the profession of this district, and will, by the discharge of his duties as President of the Association, materially enhance his own reputation, and bring credit to the body of which, for the next twelve months, he becomes the head. (Applause.) Bear with me for a moment whilst with loving and reverent hand I would lay a memorial wreath upon the recently closed graves of those who since our last anniversary have gone "to that bourne whence no traveller returns;" for the losses we have sustained by death this year has been a remarkable one in our annals. *Facile princeps* is Syme, then follows Simpson—(applause)—and with an interval Minchy and Jeaffreson, men of mark, long familiar not only to us but to the world—with whom as associates we were privileged to hold secret converse; these will meet us no longer in our annual gatherings. It is not for me to draw comparisons, or to mete out the eulogy they each deserve. They are now beyond the reach alike of criticism and praise, but their works endure, and by these they will be judged. It will long be for us a subject both of pride and pleasure that in their lives they were of us, and that our objects secured their sympathy and approval. (Applause.)

Inaugural Address.

Dr. Charlton, the in-coming President, then delivered his inaugural address. He offered the members a cordial welcome to Newcastle-on-Tyne, to the history of which he alluded, and then went on to consider its hygienic state, and to refer to other medical and social problems. Having shown that from its position and other circumstances the town ought to be a healthy one, he observed that "unfortunately of late years the death-rate has been comparatively high; nay, about five years ago it rose so much that it seemed to confirm the idea long before put forth by the Cholera Commission of 1854, that the great mortality was occasioned by the neglect of sanitary regulations. It must be confessed that Newcastle suffered terribly in the cholera epidemic of 1853; but it was not the poorest and most wretched-looking parts of the town that were then most severely visited. By many it was maintained that the then deficient supply of water, or the contamination of that necessary fluid by overflowings and filtrations from cesspools into badly-protected wells, favoured the spread of the disease. In reality, however, cesspools are not an 'institution' in Newcastle; they hardly can be said to exist; and for the last twenty years and more, water for household consumption has been supplied from large reservoirs twelve miles from the town, and free from all danger of contamination. For ourselves, after most careful examination, we have been unable to discover the connection, in this instance, between cholera and the water supply, though we fully recognise the probability, nay, almost the certainty, of water being the great medium by which the choleraic and other poisons are introduced into the system. With the generally high rate of wages, the abundance and cheapness of provisions, and of firing, the disadvantage of overcrowding temporarily might be partially counteracted, were it not for the unfortunate and well-known fact that high wages are apt to induce a corresponding amount of debauchery and drunkenness among our labouring population. It is not of the pitmen we here speak, but of the workmen employed in our great manufactories. The pitmen form a class apart; and though many of them make it almost a rule to get drunk on the fortnightly pay day, they are, on the whole, a quiet race, and their occupation is by no means an unhealthy one; but the same cannot be said of many of the other industries followed in this neighbourhood. We have large lead works on the Tyne, both of white and red lead, and our hospital is rarely without several cases of lead disease from the white-lead factories. We often have this malady in its most aggravated forms, and it is observed that the women suffer more than the men, as it is the former who are chiefly employed in handling and stacking the carbonate of lead. It has been maintained that the greater intemperance of the male workmen acts as a prophylactic against the lead-poison; but we are inclined to refer their greater immunity rather to the nature of their work. The iron and iron ship-building works on the Tyne may be said to have existed for the last thirty years; and in these great establishments the health of the workmen ought, from the nature of their occupation, to be reasonably good. The unfortunate improvidence and drunken habits of many of these highly-paid operatives tends, however, to produce disease; disorders of the heart and kidneys are frequent, while phthisis among these men is comparatively rare. We are not advocates of total abstinence from alcohol; we recognise fermented liquors as a gift of Providence; but, under the present drinking usages of this country, they have become an absolute curse to the labouring population. We have alluded to the facilities possessed by Newcastle for drainage into the Tyne; and we confess we spoke thus with some hesitation, conscious that when in after days these words of ours may fall under the eyes of our more enlightened successors, they might wonder that such an idea could be entertained in an assembly of grave medical practitioners. We recognise daily the important part that water plays in conveying the germs of disease, and we speak of draining our town into a tidal river. The Tyne is, indeed, at present a greatly polluted stream at Newcastle; but we foresee the day when its waters will become pellucid as of yore—the day when the most fruitful in evil of all modern so-called improvements, the fœtid water-closet, will have been replaced by the dry earth or dry ash system; when the liquid sewage, too, will be utilised, and little but pure water shall rejoin the waters which flow in the parent stream. "On referring to the immediate business of the Association, he said that hitherto one great and paramount obstacle to progress was the multiplicity of sources whence licences to practise medicine could be derived. Against this

crying evil there is but one remedy—a single portal, by which all should enter the profession; a single but searching examination for the licence to practise. He then remarked on the legislation on the subject; and on the office of coroner he recommended that, with a well organised magistracy, the office of coroner might be altogether dispensed with, and be replaced by specially instructed medical inspectors in each district. Touching the work before them, he said: "We have before us the prevention of disease by sanitary laws; we have the subject of hospital improvement, so admirably inaugurated by Captain Douglas Galton at the Leeds meeting; we have the coming struggle regarding the repeal or the extension of the Contagious Diseases Act, where a band of so-called strong-minded women and weak-minded men are striving to reverse the verdict of the wisest and the best among the medical profession."

Professor Stokes, of Dublin, moved, and Dr. Paget seconded, the usual vote of thanks to the retiring President. In doing so each referred to the rejection of the Medical Bill, and expressed their regret; whereupon Mr. Husband, of York, and Dr. Chadwick protested that the subject ought not to be introduced, and it was accordingly dropped.

A vote of thanks to the Mayor and Sheriff of Newcastle was also carried by acclamation.

The Secretary read the annual report, showing an increase of members in the district, due mostly to the zeal of Dr. Phillipson. The report stated that Mr. Hutchinson had resigned the Editorship of the Journal, and that the post had been given to Mr. Hart.

The report was adopted on the motion of Dr. Beatty, seconded by Dr. E. Smith.

Mr. Watkin Williams was re-elected General Secretary at a salary of 300*l.* a year.

The accounts were submitted, and a vote of thanks passed to the auditors.

Dr. Elliott withdrew his motion to publish an annual volume of *Transactions*, as also did Rev. Dr. Bell his more important one on the constitution of the Committee of Council.

Second Day.—Wednesday.

The day opened by a breakfast given to members by Dr. Gregson, the Sheriff of Newcastle, which naturally went off with considerable eclat.

The Sheriff said, in welcoming the members to Newcastle as Sheriff of this ancient Corporation, that in its name and his own he bid them most hearty welcome. He was sure this town had just reason to be proud that this Congress was now assembled within its walls, comprising so many gentlemen of the highest acquirements, so distinguished by profound research and practical experience, from distant parts of Great Britain and Ireland, all animated by the same motive, all able and willing to impart the results of their research and experience in the noble science and art of curing and alleviating the ills to which flesh is heir. He trusted that this meeting would form a bright era in the cause of progress in the service of humanity. He also trusted that through their meeting many lasting friendships might be formed, and pleasing recollections of it may endure. He also hoped that this town would reap the first fruits of their labours in sanitary science, and that, in the arduous duties in which they would be engaged, one of the greatest blessings may not be wanting, but that all may experience "a good digestion waiting on appetite, and health on both."

After breakfast the Council held a meeting, and at eleven o'clock the second general meeting took place, in which it was decided that the next meeting should be held at Plymouth, and that Dr. Whipple, of that town, should be President.

Sir William Armstrong was elected honorary member of the Association. In the evening Sir William gave a splendid banquet to a large number of members.

At noon Dr. Gibson gave the address in Medicine, taking for his subject the treatment of gout and acute rheumatism by rest. In the afternoon the sections met, but we are compelled to postpone a report of their proceedings.

The President gave a soiree at nine p.m. to members and friends in the Town Hall. Upwards of 500 ladies and gentlemen attended. In addition to the gay decorations of the Hall, the objects of art and scientific interest exhibited were examined by many with much pleasure. Among these were a number of ornithological specimens, lent by Mr. Hancock; archæological collections, contributed by the Antiquarian Society and the President; a series of permanent photographs, illustrating Mr. Swan's "carbon process," exhibited by Mawson and Swan; and porcelain, the property of the late Charles Dickens, shown by Mr. C. Lister. The principal table was devoted to the display, under a series of microscopes, of some of the most remarkable results of modern zoological researches in the collection of deep-sea organisms, placed at the service of the President by Dr. Carpenter, V.P.R.S. During the evening Mr. Rea executed several choice selections of music.

Third Day.—Thursday.

The President of the National Temperance League gave a breakfast in the Queen's Head Hotel, at which some eighty medical men were present, and where the objects of the League were ably stated by the President, and some discussion ensued, in which Drs. Wood, Sutcliffe, Stanley, Haynes, De Mey, Rutherford, Underhill, and the Sheriff took part. The third general meeting was then held, when Dr. Waters presented the report of the Direct Representation Committee. Owing, however, to this report not having been printed, and the few members present at its reading, the discussion was postponed to the next day.

Dr. Heath's Address.

At eleven o'clock the address in Surgery was delivered by Dr. George Y. Heath, Surgeon to the Newcastle Infirmary. He took for his subject operative surgery, and spoke of its three characteristics "of audacity, its conservatism, and its success." He considered that modern operative surgery was characterised by the magnitude of its proceedings, its respect to the integrity of the human body, its reticence of the knife, and the superiority of its results. Speaking of the large extent of usefulness to which it might be applied, he remarked that it stretched out its hand in fresh regions, and dealt with organs once considered out of its reach. It hesitated not to take the greatest responsibility, if only its audacity were justified by a well-grounded hope of eradicating disease. Paradoxical as it might seem, while in one direction it was just acquiring new dominions, in other characters it was laying down the knife, or it substituted milder for more severe operations, and shrunk from any unnecessary mutilation of the human frame. In its milder and more conservative measures it realised greater and more uniform success than in former days. There were three characteristics of modern surgery which for shortness might be spoken of as its audacity, its conservatism, and its success. There would be no difficulty in recalling examples of the audacity of modern operative surgery. Operations which but a few years ago were accounted unjustifiable were now practised on a firm basis of success. The term "conservative" applied to surgery dated from 1852. He then proceeded to give examples of cases where the use of the knife had been abstained from. A friend of his had had the case in hand of a man having had his leg cut by glass. The gentleman had not his instruments with him, and consequently could not perform any operation; and he therefore endeavoured to staunch the blood by bindings; but he found it impossible in that way to succeed. It at last occurred to him to bend the knee, and, doing so, he found the bleeding so mitigated that he was enabled effectually to stop it by the application of bandages. From the results of experiments in the matter, he was led to believe that it was but fair to infer they had a blood-controlling agent of considerable power which could be applied on the shortest notice, not dangerous in itself, which certainly may be relied upon to restrain bleeding, at least temporarily. He then illustrated the success attending modern operative surgery. He produced models of a leg which had been entirely crooked at the ankle, which, he said, had been straitened by means of the removal of bones. This was twenty years ago, and he was told by the owner of the leg that, excepting a slight shortness of the limb, he experienced no inconvenience whatever from it, but, on the contrary, it was a good serviceable limb. He gave other examples, and then added:—"But we must not boast too much; we must confess that there are other foes whom we cannot yet overcome; still wide domains where the great enemy Death still remains victorious, but which it is for us and our successors to rescue from his scythe and bring under the dominion of the knife. Nevertheless, what I have been able to relate will suffice to show that operative surgery has not stood still while other arts have advanced, and that if we do not occupy the foremost place, we are at least well to the front, in that glorious race which they win who do the most to diminish human suffering, to prolong life, and to elevate the condition of man."

A vote of thanks, moved by Dr. Southam, and seconded by Dr. Wheelhouse, was accorded Dr. Heath for his valuable

address. The several sections met again in the afternoon, and in the evening the public dinner went off satisfactorily.

Last Day.—Friday.

At eleven o'clock in the morning the concluding general meeting was held, where more discussion took place than at other meetings, in consequence of it having become clear that the Council had in several particulars acted contrary to the wishes of members. The opportunity was therefore seized to bring out in other matters the differences of opinion that exist.

It was clear to every one present that the ruling body is in direct antagonism with the Association, or at any rate a large portion of it.

Dr. Ransom read the report of the committee "On the Observation and Registration of Disease."

Professor Paget moved the adoption of the report.

Dr. Waters seconded it, and it was carried.

The report of the committee appointed to obtain direct representation of the profession in the Medical Council was next read. The adoption of the report had been moved on Thursday by Mr. Husband, and seconded by Dr. Stuart.

Dr. Acland moved an amendment, "That this meeting learns with regret that a committee of this Association have refused, in the name of the Association, the offer of Mr. Forster, the Vice-President of the Privy Council, to grant a committee of the House of Commons at the commencement of next session to inquire into the question of the representation of the profession in the Medical Council: that in consequence of that refusal the Government declined to proceed with the Medical Bill."

Dr. Embleton seconded the amendment.

Dr. E. Waters opposed it.

Dr. Beatty expressed his great gratification that the bill had been withdrawn.

Professor Paget spoke in favour of the amendment.

Professor Bennett against it.

Dr. Rumsey also spoke against the amendment. He feared the profession had missed the opportunity of getting a good bill.

Dr. Hecstall Smith supported the report, as also did Dr. Southam and Dr. Chadwick.

After a few words from Mr. Husband, the amendment was put to the meeting and lost.

On the motion of Mr. Thomas Underhill, seconded by Dr. Tilt, the members for the ensuing year of the Medical Reform Committee were appointed.

Dr. Chadwick moved a vote of thanks to Dr. Sibson, the President of the Committee of Council of the Association.

Dr. Falconer seconded the motion, which was carried.

Dr. Acland moved that the grateful thanks of the members of the Association be given to the Mayor, Sheriff, and Corporation of Newcastle, the Committee of the Literary and Philosophical Society, the Directors of the Savings Bank, the Directors of the Gas Company, the Committee of the Newcastle Infirmary, the Council of the College of Medicine, the Committee of the Natural History Society, the Committee of the Society of Antiquarians, the local secretary (Dr. Philipson), the local treasurer (Dr. Humble), Dr. Arnison, Mr. Luke Armstrong, Dr. Banning, and other local officials, to the manufacturers who had laid open their works for the visits of the members of the Association, and especially to Sir William Armstrong.

Dr. E. Waters seconded the proposition, which was carried by acclamation.

Dr. Stuart moved, Dr. Hecstall Smith seconded, and it was carried, that a State Medicine Committee of the Association be appointed.

On the motion of Dr. Rumsey, seconded by Dr. Stuart, the appointment of a Parliamentary Committee was referred to the Committee of Council.

Dr. Chadwick moved a vote of thanks to the President of the Association, which was seconded by Dr. Sibson, and carried by acclamation.

Dr. Charlton having suitably replied, the business concluded, and the majority of the members present left the town to attend a special Convocation of Durham University.

Convocation of the Durham University.

This special Convocation of the University of Durham, for the purpose of conferring the honorary degree of D.C.L. on seven of the members of the Association, was the first business of the afternoon. The convocation assembled in Bishop Cosin's Library, shortly after two o'clock. The warden of the University, Dr. Lake, the recently appointed Dean of Durham, presided, and was supported by all its other officers, and church dignitaries, connected therewith. The body of the hall was filled with a gay assemblage, in a great part consisting of ladies, and the gallery was crowded with gentlemen from end to end. The first called upon to receive the degree was Dr. Edward Charlton, the president, and he was warmly applauded. The other gentlemen were all greeted with the warmest acknowledgments as they stood before the Dean, and received the distinction. After Dr. Charlton they came in the following order: — Charles Chadwick, M.D., F.R.C.P. (Leeds); Randle Wilbraham Falconer, M.D., F.R.C.P. (Bath), treasurer of the Association; Francis Sibson, M.D., F.R.S., F.R.C.P. (London); Henry William Acland, M.D., F.R.C.P., LL.D., F.R.S., hon. physician to H.R.H. the Prince of Wales, Regius Professor of Medicine and Radcliffe Librarian in the University of Oxford; George Edward Paget, M.D., F.R.C.P., Linacre Lecturer in the Medical University of Cambridge, and President of the General Medical Council; and William Stokes, M.D., F.K.Q.C.P., LL.D., Regius Professor of Physic, University of Dublin, and Member of the General Medical Council. Professor Stokes was greeted with quite an ovation on stepping forward to receive his degree, and, in the course of a highly eulogistic speech by the Rev. Warden, the hearty cheers of the brilliant assemblage were both loud and frequent.

Service in the Cathedral.

After the Convocation had been dissolved, the whole of the visitors repaired to the Cathedral, and broke up into parties, who were led by several local gentlemen compet ent to give an interesting description of the principal objects in the ancient pile. The largest of these parties was under the guidance of Dr. Charlton, and there was ample scope for his descriptive power and antiquarian knowledge. Full Choral Service commenced at four o'clock, and was well attended.

Dinner in the Castle.

A cold collation was served up in the Castle Hall at five o'clock, and upwards of two hundred of the members of the Association sat down. The Very Rev. the Dean of Durham (Dr. Lake), Warden of the University of Durham, occupied the chair, supported on his right by Dr. Charlton; the Lord Bishop of Durham (Dr. Baring); Dr. Stokes; Archdeacon Prest; Dr. Paget; Dr. Hamilton, Archdeacon of Lindisfarne; and Dr. Embleton. On his left were Dr. Whipple, President-elect of the Association; Dr. Falconer; Dr. Sibson; Dr. Chadwick; Dr. Husband; Dr. Gregson, Sheriff of Newcastle; the Rev. Canon Eade, and Professor Acland. The rev. Chairman first proposed, in one toast, "The Church and the Queen," which was replied to by the Lord Bishop of Durham, who expressed the pleasure he felt in welcoming the members, and spoke to the close union which exists between the clergy and the medical profession. Referring to the period when he was a parish priest in London, his lordship testified to the great assistance he had received from gentlemen of the medical profession, making mention of Dr. Burrows and Dr. Paget, and one for whom he had the greatest regard and esteem, who, had he been spared, would have risen to the highest position in his profession—Dr. Baly. He was killed on his way to Windsor Castle by a railway accident. There was no body of men more large-hearted and self-sacrificing.—The Chairman then gave "Success to the British Medical Association, coupled with the health of Dr. Charlton."—Dr. Charlton, in responding, referred to the manner in which they had been enabled to receive the members of the Association, with the help of friends in Newcastle and some a little further south—friends in the glorious old University of Durham. He was sure they would all carry away with them a lasting recollection of their reception by the University of Durham.—Professor Acland also acknowledged the toast, and gave the health of "The Dean and Chapter of Durham," to which Dr. Lake replied in felicitous terms.—"The Mayor and Corporation of Durham," was proposed by Dr. Husband, of York, and responded to by Dr. Boyd, of Durham.—Dr. Paget gave the next toast—"Prosperity to the Newcastle College of Medicine," and spoke of its connection with the University of Durham. He coupled with the toast the name of Dr. Embleton, who, in replying, gave a short history of the College. It was founded by Sir John Fife and Dr. Greenhow, as a school of medicine, in 1834, and became part and parcel of the University of Durham in 1852.—Dr. Charlton proposed "Prosperity to the

University of Durham," remarking that he could see a great future for it, and that it would in time become the grand scientific University of the North. Of the kindness of the Dean and Chapter of Durham on the occasion of the wind-up of their meeting, he said he could not speak but with the warmest gratitude.—The Dean of Durham acknowledged the toast in a most humorous and instructive speech.—The health of "The Distinguished Strangers" was given by the Archdeacon of Durham, and replied to by Dr. Stokes.

The Medical Press and Circular.

WEDNESDAY, AUGUST 17, 1870.

AT NEWCASTLE.

The British Medical Congress has occupied four days of the past week at Newcastle-on-Tyne, and even amidst the din of war we may be expected to say something about it. It was a pleasant enough time for those of us who determined to take notes quietly instead of availing ourselves of the privileges of the press, and this course is certainly justifiable in the case of an Association that supports its own journal—that, in fact, spends all its available cash on its own periodical. A good many members confided to us their notion that this was altogether an error, and were inclined to support the movement for a yearly volume of *Transactions;* yet, when the motion to consider that came on, they failed to put in a worthy appearance.

This is really remarkable in the light of the Treasurer's report, which shows out of an income of upwards of £5,000 the magnificent sum of about £15 devoted to scientific research. "Was ever a more ridiculous result?" exclaimed not a few. "But after all," said others, "the Association does not exist for scientific purposes." That is all very well to talk about to the public; but there are a dozen societies that would be glad of all the really good papers read. There are plenty of journals to publish valuable original communications, or to ventilate professional questions—it is our business to take a respectable holiday once a year, and let John Bull fancy his doctors are at their usual disinterested employment for his behoof. Besides, it is pleasant to see such an assembly of doctors, and no one who has not had the opportunity of journal observation would ever dream how few are the distinguishing characteristics of the British doctor.

It is not for us to decide these points—that is, not for us as journalists. The writer, as an individual member, has a right to form his own opinion as to the uses of the Congress, and to continue to pay his guinea a year, or to resign, as to him may seem fit. Well, he thinks Newcastle worth the money, and perhaps Plymouth may be, and that is to be the next greeting place, when he hopes to meet as many worthy members of the Profession as the Northern counties produced.

When the President, in a few graceful remarks, touched the vexed question of Medical Reform, curiosity was at once excited, and this only redoubles when Drs. Stokes and Paget, in proposing a vote of thanks, revealed how great was the difference between opinion of the leading minds in the Profession, and the committee that has assumed to represent it during the last twelve months. Such men may, as occasion requires, rise above everyday etiquette, and seize a favourable opportunity to speak a word in season; and, in spite of the reproof of the Association's leaders as to the timeliness of their remarks, we hail them as an indication that the boasted numbers of the Association are not to be allowed to over-rule independence of thought, or the small Committee of Council to arrogate to itself a position to which it is not in the least entitled. We cannot forget that the Leeds meeting, when fairly appealed to, asserted a principle which the committee has altogether evaded. In this we consider the committee to be reprehensible, and not for any number of agreeable meetings would we condone such a fault—not a mere mistake, but a deliberate determination not to listen to the voice of those who alone have the right to decide on great measures.

"Ah! but they mean right!" said one when we urged this view of the matter. "Perhaps they do; but then let them do right," reply we. Did we not hear the representatives of this Association pretend to speak in the name of the Profession, but a short time ago, to members of the House of Commons? and did not others then and there cry out against the assumption, and assure the few legislators present that such were not the views of the Profession? How well it might have been added that these gentlemen did not really represent the Association, inasmuch as they had agreed together to ignore the decision of the general members on the only occasion on which the matter was put before them. We had many other things to say of the meeting, but space fails. Those who were present need no recapitulation of the lighter matters. Those who were not will find a condensed report in another part of this number. As to practical matters, we shall gather up the fragments to present to our readers in future numbers.

Notes on Current Topics.

A Sad Story from the Cells.

At Cardiff, David Howells was sentenced by the local justices to a month's imprisonment with hard labour. He had not taken food for two days prior to his conviction, but "had the horrors"—from drink. In prison he had been placed on the treadmill, and, whilst attempting to do it, the chief warder, lynx-eyed official as he is, remarked that "he appeared to be unwell, and suffering from the effects of drink," yet he worked him till noon, and then took him to the doctor's assistant who prescribed for the prisoner, if not the "pump," something analogous to it; subsequently he was re-harnessed to the mill, and "did" his nine hours. It was on being released from the mill that David Howells became so restive and violent, that Dr. Paine, the gaol surgeon, had to be sent for. Dr. Paine and his assistant (Dr. Morgan) visited the "restive and violent" prisoner—ordered him brandy and arrowroot, and prescribed medicine. Two prisoners "with instruc-

of the night, David Howells ceased to become violent and laid aside his restiveness, for his spirit had bounded from the grasp of the vigilant guards that encompassed it—he had died!

On the body of the prisoner an inquest has been held. The verdict delivered by the empanelled jury has not met the approbation of the inhabitants of Cardiff, who demand further and fuller inquiry into the case; and justly, if the real facts be as thus represented by the local Press.

Cheap Dwellings for the People.

Now that the Education Bill has passed Commons and Lords, and that parents and guardians will in future be compelled to se that the youths of their respective charges receive—at least—the standard amount of education, it may be advisable to invite the attention of our readers to the consideration of the dwellings of many of those persons for whose interests, in an especial manner, the Education Bill had been introduced—namely, the poor, and the industrious poor! These terms not being synonymous, we thus draw the distinction, for neither in this vast metropolis nor in districts less populous is there complete freedom from that poverty induced, if not stimulated, by idleness, unnecessarily, nevertheless, persistently maintained and transmitted from parent to progeny, thus developing the street-Arab and his "dolly," besides persons of even a less reputable class.

Undoubtedly, the wretchedness and filth (superinduced by density of populace and over-crowding) of many of the residences of the poor, exercise considerable influence on their habits, and may be held forth to palliate, if not to completely excuse, their shortcomings, and, until better accommodation at *much less rent* than at present be offered for their acceptance, improvement in their condition, morally or physically, will be slow indeed. 'Tis true that an important step in advance has been made by the Peabody and the Industrial Dwellings Companies, but it is to be regretted the directors of the former look more to the realization of a large parentage for the capital invested, than to the supplying of an effective antidote for those crying evils—over-crowding and high rents.

We may be told that in London the wages of the mechanic are large, and that *he* can pay a *fair* rent for house accommodation. Very true, but let us not forget that trade in London is very precarious, and to be "knocked out of work," and for months to remain so, is an event in some trades consequent on their very nature, whilst in all trades war, peace, and the state of the money market, exercise considerable influence for good or evil; still the rents run on!

To the tradesman's auxiliary—the labourer—on his guinea, or less, per week for a portion of each year, and on his "luck" during the winter months, and oftener; to the costermonger with his barrow, blue nose, and anxious looks, depending on the "turn of the tide" to turn an honest penny on mack'rel, prawn, or mullet, and on the botanical condition of Covent Garden market, from day to day; to the industrious poor, in short, the industrial dwellings bring little benefit.

Give the London poor healthy house accommodation at rents equal to about ten per cent. on their earnings (not 25 and 33 as at present for vile accommodation), and a gigantic stride in the right direction will be made; then firm groundworks will be laid, whereon enforced, healthy, endurable, and truly philanthropic Educational Schools will be constructed, so that in a little time, following the example of that monarch who declared the walls of his city were not formed of rubble masonry, but of soldiers, and that each soldier was in himself a perfect brick; we, in humble imitation of the Royal wit, may be in a position to exclaim, "We educate, but our first lesson-books are taught at the homes of our pupils."

Certificates.

Some time ago we directed attention to the impropriety of demanding answers to a number of questions from the medical attendants of poor patients prior to admitting them into public institutions. We instanced the outrageous questions put in the certificates for the Ventnor Hospital.

The Seaford Convalescent Hospital is rather less exacting, but still requires this form to be filled up by the patient's last attendant:—

Name and age .....
Address .....
Is the patient eligible (see below), and able to bear the journey to Seaford? .....
How long convalescent, and from what disease? .....
What has been the general plan of treatment? .....
Remarks (confidential). .....
Signature of physician or surgeon who has had charge of the case .....
Date .....

CASES INELIGIBLE.

1. Children under ten years of age and helpless persons.
2. All disease requiring active medical or surgical treatment.
3. Pulmonary consumption, beyond the first stage of the disease.
4. Ulcers with copious or offensive discharges.
5. Convalescents from eruptive and other fevers of an infectious nature, contagious diseases, so long as they are capable of communicating infection.
6. Persons subject to epileptic fits.
7. Persons of immoral character.
8. Persons who have been previously guilty of misconduct in the Hospital.

Note.—The Institution is exclusively intended for convalescents.

The Horse Guards and Beards.

The *Globe* says that an order has been promulgated directing that officers are not under any circumstances to wear hair on their chins.

Is this a Ministerial preparation for a campaign? Will it encourage recruiting?

Epsom College.

The Rev. Dr. West, D.D., of St. John's College, Oxford, has been elected head-master of Epsom College. Dr. West is a Vice-president of the College of Preceptors, and took at Oxford a first in Mathematics and a second in Classics. Dr. West has been head-master of Brentwood School since 1852, and is considered to be a gentleman of considerable tact and experience.

"Mal" Midwifery Practice.

THE unqualified assistant of a Battersea surgeon has been defendant in an action instituted by a Mrs. Pike, the wife of a journeyman baker, he having persistently prescribed brandy and soda-water in a case of irritability of stomach when labour was impending. Mrs. Pike not having improved under this brandy and soda-water treatment, two practitioners were called in, who decided to bring on premature labour by giving five-drop doses of prussic acid as recommended by Churchill, and with apparent benefit in this case. Mr. Godman was condemned in £5 damages. His defence for the most part went to show that he had attended nearly 2,000 obstetric cases, which he considered sufficient to justify his treatment of Mrs. Pike.

Leeds and Vaccination.

THE Leeds Inspector of Vaccination has issued his report for the June quarter. It shows that out of 407 children born in the township during the last quarter of the year 1869, and unvaccinated up to April, 1870, 51 died before the vaccinal period; 27 had been removed from the township; and the health of 22 was so precarious as to justify postponement. Fourteen persons died (in the township) of small-pox during the year.

The Inspector's Report states that the "Unanimous desire of the Medical Profession to encourage vaccination is operating most beneficially."

"What will they do with it?"

THE *Lancet* "purposes shortly to place before the Profession the *draft* of a Bill for the *accomplishment* of the *necessary* measure of Medical Reform."

N.B.—The italics are *not* the *Lancet's*.

The Poor Law Board and the Birmingham Guardians.

THE Guardians of the Birmingham Poor have again prayed for time in order to arrange with their Medical Officers. The Poor-law Board has granted the prayer, but we greatly fear the poor of Birmingham may, for another year, suffer from the effects of such an unsatisfactory arrangement.

The Poor-law Board should at once see justice done to the Medical Officers, and permit no further procrastination. The interests of the poor demand it, and their interest the Medical Profession have sincerely at heart.

Illness of Admiral Farragut.

A SPECIAL telegram from Philadelphia states that Admiral Farragut, of the United States Navy, is very ill at Portsmouth, New Hampshire, and is not expected to live.

Medical Reform Union.

THIS body scarcely any longer possessing an existence, the late Executive have issued a "retrospect" which deserves attention. They have, indeed, fallen into a state of confusion about indirect and direct representation; but this is of little consequence. The Union pronounced the single word "representation," and did not attempt to settle off-hand the method. Their Birmingham brethren, with true pluck and rare sagacity, have done more in a year to promote Medical Reform than the more ambitious British Medical Association has done for the last decade, or is likely to do in the next. There is still a trifling balance due to the treasurer, which we hope he will not be allowed to lose. A few stamps from each who signed the memorial, but has not yet subscribed, will settle this.

Bullet Extractor.

SURGEON TUSON, of the Bengal Army, has lately described a new bullet extractor. At this time, when war is raging on the Continent, it will be a serviceable instrument to the many poor sufferers who are wounded.

Evaporated Milk.

ONE of the most recent expansions of trading speculation has taken the direction of milk preserving, and several companies have been formed for the purpose of evaporating good milk, and reducing it to a saleable and permanent state. The well-earned suspicion of the public as to the sophistication of trade preparations has, of course, been applied to preserved milk, which would, indeed, seem to be the very article in which the greatest temptation would arise to adulteration.

The *Vierteljahresschrift für Praktische Pharmacie* has by careful analysis entirely reassured us on the point, and shown that the preserved milk is really what it pretends to be, and possesses all the qualities of a concentration of the best milk. For the purpose of comparison, the analyst made for himself a standard sample of condensed milk, and on investigation found that the four bought samples were almost identical with the standard in composition, and some of them even richer in cream. We have also submitted to careful analysis the Irish preserved milk of Mr. Newnham, of Mallow, and find it corresponds exactly with the statements of the purveyor.

The Monthly Nurse.

FREQUENT complaints reach us respecting the great want experienced in country districts of properly trained and qualified monthly nurses. It is not always desirable to send to an institution for a nurse, nor at all times feasible; the circumstances of the case will not always permit it, and when they do, the newly-arrived nurse may not prove suitable in many respects—in manner, appearance (for some ladies are particular), or method of performing her duties; accordingly, it is most desirable that in each district there should be a qualified obstetric nurse possessing a midwifery diploma. Ireland is fortunate in having a strong *corps* of qualified midwives at the Rotundo Hospital, who study for six months, under able teachers, the important requirements of their office, and when educated, are admitted to examination, and if considered fit, obtain a diploma. It is not always pleasant to have a woman enlarging upon the nature of the case in technical language at the bedside of a patient; but we believe the midwives who leave the Rotundo know better than to talk "shop." These women, who are generally widows, find employment in the poor-law unions, and are valuable assistants to the overworked, underpaid, dispensary or poor-house doctor. They usually obtain twenty pounds a year, irrespective of a little private practice. They are trustworthy women as a rule, in whose charge a patient is safe. We understand many

tions" were also told off to restrain him, but, ere the close of these qualified, well-trained women experience a difficulty in getting employment. We wish there were more of them in England, and that in each district the parish authorities would appoint one. The Poor-law medical officer may object to this; but if he came to consider how much midwifery work he must do for twenty pounds, which very frequently involves a serious encroachment on his time, he would freely surrender his lower class midwifery to them, whilst in a better class of patient he would find them valuable and reliable auxiliaries. If the English Poor-law system could allow such an arrangement as to pay a uniform scale of salary to medical officers, dispense with extras, and introduce duly qualified midwives into each district, under the *surveillance* of the doctor, it would be desirable to all parties.

Medical Evidence in Cases of Railway Accident.

At the York Assizes last week a miller and a maltster named Hatfield, brought an action against the North-Eastern Railway Company for alleged injuries sustained on their line. It appears that in August of last year, whilst travelling between Redcar and York, he sustained an injury to his hip by the overthrowing of the carriage wherein he travelled. The following is a condensed summary of the medical evidence given at the trial, which bears us out to the letter in the remarks which we made only a few weeks back in these pages respecting medical evidence in cases of railway accidents:—

"According to several surgeons of eminence who were called for the plaintiff it was beyond all doubt that he was still lame and suffering. It was doubtful if ever he would get well. He would not get better, even with luck, for two or three years. According to several surgeons of equal eminence, called on behalf of the company, there never was anything at all the matter with him. He looked better and stouter than ever he was before, and *the accident seemed to have done him good.* The plaintiff's surgeons had tested the thigh by the thermometer and galvanism. The defendants' surgeons stated that these tests were apt to be illusory. The defendants' surgeons stated that the limb had not decreased in size, but the plaintiffs' surgeons said it was slightly decreased, and could not have been more so unless paralysis had set in."

We are well aware Railway Companies are frequently mulcted; but the idea of an accident injuring a man's hip seeming to have done him good is too absurd to be passed unnoticed. We wish our brethren were more united, and that at the sacrifice of a fee they would uphold the dignity of their calling more.

The Contagious Diseases Act.

We observe that a series of letters, originally published in The Medical Press, commencing in June 26th, 1867, and terminating April 6th, 1870, from the pen of a much respected correspondent, "E. L.," are now reprinted in pamphlet form. It will be remembered "E. L." was warmly opposed to the Contagious Diseases Act, and advocated the examination of men, whom "E. L." states are the true originators and propagators of venereal disease. "E. L." comments with ability upon the proceedings of the Venereal Committee of the Harveian Society; submits for consideration extracts from the writings of Jules Janin—the Charles Dickens of France—and relies upon the well-known book of Mr. Acton, and the authenticated statistics given by the *Westminster Reviewer* as sufficient to repeal the Act.

Attractions of the Navy Service.

At the Navy Medical Examination, held this week, there were twenty-five vacancies and fifteen candidates.

Jeames on the Emperor's Health.

The *British Medical Journal* assumes, in its last issue, the usual pompous affectation of special intelligence as to the health of Crowned Heads. All that the Editor knows about Napoleon's health is freely disclosed. Marvellous to relate, especially in the case of a general on the battle field, His Majesty suffers from "exhaustion and fatigue." His Majesty, also, the oracle informs us, is displaying "wonderful serenity under serious physical and mental trials." Without the inspiration of any "good authority," such as our contemporary boasts of, we can positively confirm these remarkable and unexpected revelations, though we don't think it necessary to do so with the addition of big type and extra "leading."

The Prospects of the Medical Bill.

The effect of his defeat on Mr. Forster and the Government seems to be almost the same as it has on a pettish child. Mr. Forster "won't play any more" because he has not been allowed to do exactly as he liked with the Profession. In diplomatic phrase he has replied to a question put by an hon. member that the Government cannot undertake to promise that they will introduce next session a bill for the Amendment of the Medical Acts.

This announcement may mean more than it conveys. It is as much as to say that the Government have gone out of their way to trouble themselves about the Medical Profession, and, as the doctors would not have what they offered to give them, they might do without. We advise Mr. Forster not to calculate on being let alone. By self-sufficiency, obstinacy, and apprehension of the vote of the University Member, he spoiled what otherwise might have been made a passable measure.

But the Profession is thoroughly aroused, and the Government may be assured that one or other of the half-dozen members who have taken the matter in hand, will oblige them to deal with the subject. Better no bill than a bad one. The Government Bill would have made permanent most of the abuses which now must pass away before very long.

The Medical Services of Foreign Armies.

Dr. C. A. Gordon, Deputy Inspector-General, of Portsmouth, wishes to obtain information in regard to the measures in force in the armies of civilised nations for the treatment and transport of sick and wounded, whether by the medical departments of those armies or by means of philanthropic associations. He is already in possession of information of this nature in regard to several, and is very desirous to obtain similar information in regard to all. Any of our readers who are in a position to do so would do well to communicate to him particulars of the army medical administration in Russia, Spain, Portugal, Belgium, Naples, Sardinia, Brazil, Mexico, &c., &c. Our learned military *confrère* will carefully return any manuscript that may be desired.

Dr. A. Paton, of Vincennes, recommends hydrate of chloral in cerebro-spinal meningitis.

The Asylums Board.

The Poor-law Board, having at last learned to exercise some little authority over Guardians, appears, in the painful process of learning, to have forgotten its manners, and accordingly has been treating the Asylums Board as if it were composed of Guardians. It has even been interfering with the salary of kitchenmaids. The Asylum managers cannot be expected to put up with such impertinence, and have accordingly given Gwyder House a hint to mind its own business.

Cholera.

There are serious whisperings of the cholera plague which ought to make us keep vigilant watch, and entrench ourselves from its onset. An official notice has been issued that it is epidemic at Taganrog, and cases have occurred in Constantinople.

The slave trade operations on the coast of Africa have come to an end in consequence of an outbreak there, and diarrhœa is unusually prevalent in London.

Dressing of Wounds on the Battle Field.

It is proposed to distribute to each French soldier a small packet containing a strip of calico, a square of fenestrated linen, and a portion of charpie rendered hæmostatic by imbibition of perchloride of iron.

The advantage of such a precaution is obvious. It would afford great facility in the case of a paucity of help for the removal from the field of the wounded, a large number of whom would, and do, die for want of the help which might thus be given them.

Poisoning from Glazed Dishes.

A correspondent supplies us with the particulars of an interesting, yet serious occurrence which happened in his practice on Saturday last. The wife of a brickmaker brought home from the pottery-works a glazed dish, which subsequent events proved had been improperly or carelessly glazed. Wishing to "*pot*" some herrings, she placed the fish in this dish, and finally completed the process by cooking in the oven. The "*potted*" herrings were served and eaten at tea. All who had partaken of them, namely, a family of five members, and a neighbour, a woman, were seized with symptoms of poisoning—vomiting, violent pain in the bowels, &c. Before investigation the herrings were at first blamed; but when the dish was examined, it was discovered that the glazing had "*run*," and mingled with the acid gravy (vinegar being used). From the alarming nature of the symptoms, a good deal of lead must have got into the stomach; but we rejoice to hear that no deaths have occurred, although the youngest child was seriously affected. We advise those who contemplate pickling herrings to observe the glazing on the earthenware.

A case of cholera having occurred at Constantinople, quarantine has been established in the Black Sea.

Sir John Thwaites died on the 8th, of English cholera.

Mr. W. C. Barnish, M.R.C.S., has been elected by the Town Council of Wigan officer of health for that district.

It has been suggested that the societies in aid of the sick and wounded would do well to send out large quantities of chloroform—a boon which sometimes has run short.

Dr. Martin Furniss, of Mansfield, a much respected practitioner, died on Thursday morning (August 11th), last, after three days' illness, from choleraic diarrhœa.

Dr. Burrows took the chair at the Quarterly Court of the Society for the Relief of Widows and Orphans of Medical Men, on the 13th inst., when new grants were made to two widows and four orphans.

The Mansfield Board of Guardians, at their fortnightly meeting, held last week, proposed and unanimously carried that the salary of Mr. N. Cooper, surgeon to the workhouse, be increased from £20 per annum to £40, because of long and meritorious services. This is a step in the right direction, and a precedent which we hope other Boards will follow.

The trustees of the National Portrait Gallery have secured the well-known portrait of Charles Dickens, by Ary Scheffer. It was painted in 1855, and exhibited at the Royal Academy in the following year. The countenance is manly and vigorous, a happy medium between the showy youth with exuberant brown locks, as painted by Maclise, and the rugged countenance, with grizzly beard, of his latest period.

From "simple cholera" and choleraic diarrhœa thirty-two deaths were registered in London last week. Dr. Waller Lewis, medical officer to the Post-office, recommends the following prophylactic:—Dilute sulphuric acid, ℥iij., concentrated infusion of orange-peel, ℥iij., simple syrup, ℥xij., boiled filtered water four gallons—a wine glassful for a draught. It is stated this "*sulphuric orangeade*" was employed in 1866 with good results.

SPECIAL CORRESPONDENCE.

[from our own correspondent.]

Paris, August 9th, 1870.

In the midst of the din of battle, I write a few lines on a subject which has been occupying much of the thoughts of many excellent members of the Medical Profession in Paris the last six months. I allude to the question of whether medical education should remain, as at present, entirely in the hands of a set of State Professors, or pass into the control of any person who chooses to set himself up as a teacher to enable his students to pass the final test examination. Many conferences have been held lately on this question, and many good things have been said. The programme of the friends of free education in Paris is—absolute liberty of teaching, either by individuals or association, for all citizens whether with or without degrees; without being obliged to conform to any programme of the State. Liberty for pupils to instruct themselves, and choose their instructors wherever they please; degrees to be granted by State Examiners not chosen among these Professors who teach the science, and are appointed by the State to do so.

In Paris, at present, there are about one hundred and twenty so-called "internes," or students who reside in hospital, and who, on an average, have each some hundred patients under their care. M. Dally thinks that there

should be seven times as many "internes," in order to allow a larger number of pupils to acquire clinical knowledge.

As it is, these "internes" become afterwards members of the hospital staff, and thus there is formed a medical aristocracy. In Paris there are about 110 *Médecins des Hopitaux*. They have the spirit of tradition, because they are renewed by themselves. According to M. Dally, they make few discoveries, because the competitions they are obliged to undergo prevent them from having time to follow out original researches. These same gentlemen, he asserts, get almost all the best part of the practice at Paris, and, when a hospital man has a large practice, he neglects his hospital patients. If he has one hundred beds to visit, he sees them all in an hour. Thus, there are too few "internes," and too few doctors for the hospital patients. He considers that each hospital doctor would have amply sufficient work with twenty-five patients. Then, again, these hospital doctors are named for thirty years up to the age of sixty-five, but their hospital cases do not interest them for more than ten years. A medical man, however intelligent, who has not been an hospital man, loses greatly, since provincials always are compelled to consult hospital men. M. Dally says, that the great reform required in Paris is in the "Assistance Publique." A very able physician, Dr. Berrut, asserts that the Parisian hospital men have no time for reflection, and he is inclined to do away with the hospital system as much as possible by means of polyclinics. He observes that if the statistics of mortality of the Hôtel Dieu are looked at in 1840, we see one death in nineteen patients; and, again, of those operated on, 56 per 100 died. Simpson, he remarks, said that 825 out of 2,083 operations in hospitals died; whilst only 226 died of an equal number operated on in the country. Paul Dubois, the Parisian accoucheur, was once known to remark that it was better for a woman to be confined in the street than at the Maternity Hospital. His advice, then, is that we should take as few patients into hospital as we can. Polyclinics, or visitation of patients at home, should be encouraged. At Göttingen, Dr. Baldinger created a medical school without any hospital. He collected the pupils, and brought them to the bedside of the patients; and thus founded a university. All, says M. Berrut, who, like Simpson, are convinced of the necessity of suppressing the hospitals, where patients are killed, ought at once to act. Let them take a room, a table, four chairs, and let the patient come to see them. If operations are required, the doctor must proceed to the patient's home. At the hospital the students and the doctor listen to the sibilant rhonchi, or look at the number of the patient. In the garret, they see the wife, the children and the family.

Another champion of free medical education, M. Dupré, goes so far as to say that there should be no official Faculty of Medicine, because of the difficulty that other universities would have to struggle with it. M. Pascal Dupré, another promoter of free medical instruction, mentioned in a reunion of students and teachers in Paris, that in England superior education is not absolutely free, because, even there, to succeed, there is required a charter from the State, subventions or subscriptions. The editor of the *Mouvement Medical*, M. Pascal, however, thinks that this would not be necessary in France, because France is a democratic nation. In England, he asserts, a very small number of persons belonging to the aristocracy of land or commerce frequent the Universities; but in France the immense majority of young persons frequent schools, and a great number of them take degrees. In France superior education, if free, would prosper, because there are so many students. Dr. Stopin, in speaking on the subject of free medical education, commences with an important question. He asks, in the first place, whether he has any right to advertise the fact that he is carrying on a polyclinique? and the auditors at once respond in the affirmative. He is attempting in a most laudable way to attend women in labour at their own homes, but foresees several difficulties. First of all, it will require the co-operation of several medical men to carry on such a polyclinique as this. Next, women, once having been delivered, have need of assistance in some cases—of a nurse, for instance—for some days. He thinks that recourse may be had to women who have just been confined gratuitously, or are just about to be so; or, perhaps, some charitable persons may aid in the good work and thus do away with the murderous epidemics which take place in lying-in hospitals.

It is a difficult thing, says M. Dally, to found a free university, for all countries have not, like Belgium, municipalities, which will grant subventions of £4,000. He therefore advises that in Paris they should ask for what is their own—amphitheatres, museums, &c. M. Mallez says, that the homœopaths at Paris have just founded a hospital. The difficulty in France of getting funds is that it is there illegal to ask for alms. He thus hopes much from individual initiative in this matter. Everywhere, at present, useful teaching is carried on by means of free teaching, whether in the hospital, the dispensaries, or in the *Ecole Pratique*. For instance, at a dinner party, he was asked to give an example of this, and replied—"A few years ago the official professor of midwifery in Paris had ten pupils and £480 a-year. At that time pupils crowded round the teachings of Pajot who was then a free teacher." In the same way Dr. Dally mentions that one Professor was for twenty years without teaching, being paid all the time. It appears, indeed, that so far as students of medicine and doctors are concerned, the question is considered settled, that the Faculty of Medicine has not fulfilled its functions. Dr. Delasiauve contends that the resources of hospitals should be placed at the disposition of students, and that that Professor should be paid the most who has the most students. No privileged Professors should exist. All students should at some time live in hospital.

Dr. Wasp has some good remarks on the subject in the *Mouvement Medical* of July 17. He mentions how in 1830 might have been seen in the wards of M. Chomel, in the Hôtel-Dieu, lying among the other patients, a celebrated professor of free medical teaching, Dr. Broc, who had been followed as professor for many years by 20,000 pupils, and who was the founder of the Medical School of Bogota. In the *Journal des Connaissances Médicales* there is an amusing account of the way in which many medical men and other diploma-holding gentlemen employ their time at Paris:—"Hairdressers, public house keepers, and restaurateurs, &c., now-a-days hide at the bottom of some drawer their diploma of bachelor, which permitted them to die of hunger, and assume the apron of the publican, &c. They also become grocers—not a bad trade to live by. The misplaced vanity of their fathers desired to open to these gentlemen the entry into professions which are named *liberal*, but which give nothing liberally. It was easy for them to perceive at the outset of their career that the few lucrative positions are already occupied, and that, having lost their patrimony, they can scarcely exist. They try, however, to do so, and then it is that we see honourable professions defiled by all kinds of compromises and schemes; those who find the filth too thick and black, or the poverty too great, refuse to paddle in it. Convinced by the proverb that 'Contempt never reaches those who live by it,' many of these decide to take up some calling generally far too late in life, to be able to provide comforts for their family, as if they had commenced younger. Many of these unclassed persons enter like interlopers into journalism, and become the irritable or melancholy *habitués* of the beer shops. The moral of all of which is that it is extended primary instruction that ought to be generalised and made obligatory, and then that men should be allowed free scope to their professional individuality. The State—that is, the taxpayers—owe to no one any kind of professional instruction whatever. Great men rarely are bred in the hot-houses of schools. One journal relates that several of the fashionable restaurateurs in Paris are good Greek scholars, and laureates of the University; but they pretend often not to be able to spell, in case of injuring their culinary reputation, or put to shame their best customers—some of the dissipated classes. A famous pastry-cook, too, was well known to be an excellent writer of vaudevilles."

Correspondence.

DUGONG OIL.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Several years ago I had the honour of bringing the "Dugong Oil" into use, also to the notice of London and provincial hospital physicians, for the treatment of consumption and scrofulous diseases, and the reports subsequently submitted to me proved the undoubted value of the oil in comparison with other remedies so called. One fact proved was that patients could retain this oil on the stomach when cod-liver oil was rejected, and the remarkable and rapid gain of flesh and weight in cases of far-advanced phthisis I have medical reports to vouch for. My principal object now in addressing the profession through your widely read journal is to ask my medical brethren located in tropical countries to assist me, for the cause of humanity, in procuring the oil at a cheap rate. Unfortunately, the price is high, and the public cannot afford the expense. I have spent a considerable amount of money in obtaining the Dugong Oil, to ensure our leading chemists having some on hand; and many applications to me for more oil I regret I cannot satisfactorily answer. I find the agent I employed abroad in the East either careless in obtaining the oil, or report, in consequence of its value now being known, unreasonable prices are demanded by the fishermen. To enable medical gentlemen abroad to investigate localities likely resorted to by the Dugong, I beg to give a short description of the animal, its habits, and habitation.

HALICORE DUGONG.—*Cuvier.*
HALICORE AUSTRALIS.

This species of the aquatic pachydermata tribe is considered a native of the Indian Ocean, and principally observed among the islands of the Indian Archipelago and coast of New Holland. The Dugong are frequently seen in numbers on the Coast of Ceylon, especially along the northern shore of the island, among the inlets, from the Bay of Calpenten to that part of Ceylon called Adam's Bridge, where the water is still, and there is an abundance of submarine algæ and fuci. These creatures may be observed in troops, feeding, where the ocean is clear, at a depth of three to four fathoms, wherever the marine vegetation is abundant. The position of the mouth of the Dugong, the muscular power and mobility of the lips, garnished with ivory bristles, enable them to seize and drag up their food. The Malays endeavour to capture these phytophagous cetaceans, so also do the aborigines of Australia, the flesh being exceedingly rich, and tasting like veal, therefore, as an article of food, they are eagerly sought. The Dugong obtains considerable length and size. The caudal paddle is crescent-shaped, and a large thick upper lip falls over the lower. The skin of the body is thinly set with short prickly bristles; the anterior limbs, or flippers, are destitute of nails, and the eyes are very small. Eight or ten gallons of oil may be obtained from an ordinary Dugong. The animals, male and female, are very affectionate to each other, and especially so to their offspring. When the latter is killed, the mother scarcely leaves her enemies, and falls an easy prey. I am under the impression that the animal exists in other tropical localities of the Western World, and I should think them likely to be seen in the estuaries connected with the River Parana, South America, also the bights on the West Coast of Africa.

I am, Sir, yours most obediently,
J. McGRIGOR CROFT, M.D., M.R.C.P. Lond.,
Late Staff-Surgeon to H.M. Royal Army.

Mandarin Villa, St. John's Wood,
August 10, 1870.

P.S. The oil is exceedingly pleasant to taste or take, and a bottle of it retained its properties, and fit for use, three years after I got it, though opened frequently to exhibit to medical and other gentlemen.

ENGLISH SURGEONS FOR THE GERMAN ARMY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As I have frequently been asked about the possibility of joining the German Army Medical Service for the time of the War, it may be of interest to your readers to learn that the North German Government is ready to admit British medical men as volunteers in their army hospitals provided that they speak German, that they have the licence to practise medicine and surgery in the United Kingdom, that they place themselves unconditionally at the disposal of the North German Government, and that they have the permission of the English Government to serve as volunteers in Germany, and that of the North German Embassy, or Consulate General. The English medical volunteers will at first, at all events, not be employed on the field of action, but only in the lazarettos in the rear of the armies: this, however, would probably not prevent their seeing and doing important surgical work.

The services of English medical volunteers will be regarded as probationary during at least a fortnight, and they will receive no payment during that time, and no reimbursement for the expense of their journey; but if their services prove satisfactory, they will probably be engaged, and receive payment at the rate of from six to nine shillings per day.

I am &c.,
HERMANN WEBER.

10 Grosvenor street,
August 9, 1870.

CITY OF DUBLIN ELECTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Thursday next is to determine whether or not Sir Dominic Corrigan will represent the City of Dublin in Parliament. I, as well as hundreds of other medical men throughout Ireland, will anxiously and earnestly hope to see every member of the medical profession in Dublin record his vote on that day for the distinguished and honoured head of our profession in this country. Those who withheld their votes and influence in 1868 under the slender excuse of pressure on political and religious grounds, have now an opportunity of healing the sores they then created, and the wrong they inflicted on our profession at large, by manfully going forward on Thursday and voting for Sir Dominic Corrigan.

I am, &c.,
F. J. DAVIS, A.B., M.D.

Cremona, Swords,
Aug. 13, 1870.

Medical News.

Society for Relief of Widows and Orphans of Medical Men.—A Quarterly Court of the Directors of the above Society was held July 13th. The President, Dr. Burrows, took the chair. Fresh applications for relief were received from two

widows and four children, and grants were made to them in accordance with the necessities of the applicants. There are now fifty-eight widows and fifty-six children receiving assistance from the Society. The sum of the grants for the half-year amounted to £1,406, being an increase of £26 on the amount voted last year.

Indian Medical Service.—The Military Secretary, India Office, presents his compliments to the Editor of the MEDICAL PRESS AND CIRCULAR, and begs to enclose a list of the Candidates of Her Majesty's Indian Medical Service who were successful at the competitive Examinations at Chelsea, in February, and at Netley, in August, 1870, after having passed through a course at the Army Medical School, Netley. J. F. P. M'Connell, London and Aberdeen, 5,855 (has been awarded the "Herbert Prize"); J. O'Brien, Dublin and Cork, 5,215; J. O'M. M'Donnell, Galway, 4,878; J. Reid, Glasgow, 4,683; P. G. Mackenzie, Edinburgh, 4,418; C. Sibthorp, Dublin, 4,119; J. A. Laing, Edinburgh, 4,065; H. D. Cook, Edinburgh, 3,988; R. A. Peterson, Dublin and Galway, 3,941; T. S. Weir, Dublin, 3,681.

The Scotch Universities.—MM. Demogeot and Montucci, who were appointed by the French Government in 1866 to examine the different systems of teaching in Great Britain, have just issued their report. A previous volume was devoted to the examination of the system of secondary education; in the present one is a long and detailed account of the system pursued at her different Universities. Special attention was paid to the Scotch Universities, and the verdict of the French Commissioners is decidedly favourable; but they call attention to a grave defect. The entrance to the Universities is too easy. This, MM. Demogeot and Montucci consider, "lowers the character of the teaching, and it is necessary to give quite elementary lectures in Greek, and Latin Grammar, in Euclid and Algebra, in order that they may be within the comprehension of the ignorant classes who listen to them. The result of this is, that a great many good mechanics are spoilt in order to make of them bad men of learning. The already overstocked professions are recruited with inferior men, who would engage with far more advantage to themselves and others in some kind of trade or handiwork; and the Universities are lowered without any corresponding advantage accruing to the country." On the other hand, in noticing the superiority of the Scotch to the old Universities of England, these gentlemen say:—"In Scotland, men do not come to the Universities to win boat races and run into debt, but to work hard and put themselves in a position to earn their living."

NOTICES TO CORRESPONDENTS.

*** Correspondents not answered in the current number should look at the notices in the following week.

NOTICE TO SUBSCRIBERS.—*The Publishers beg respectfully to remind those Gentlemen who have not paid their Annual Subscription, now overdue, that the most convenient mode of remittance is by Post-office Order, or cheque, which should be made payable, in England, to Albert Alfred Tindall; Ireland, Moffatt and Co.; Scotland, Maclachlan and Stewart.*

Mr. DONOVAN.—We have not been able to obtain accurate statements on all points, but can state that vaccination in Prussia is compulsory, that every child on being admitted into a school, must produce a certificate of vaccination, and that, on the whole, the law is carried out satisfactorily. Re-vaccination is, in the upper classes, very general at intervals of from 15 to 20 years, and is compulsory on entering the army.

DR. L. W. L., Salop.—If either of the individuals whose names are attached to the testimonials you sent us, have any existence whatever—which we doubt—they belong unquestionably to the *Genus homo* quacks. As their names do not appear in the *Register*, the parties who vaunt such articles with the assumed high recommendations of medical men should be compelled to prove that such individuals have an existence, and that they *are*, what they wish to convey, legally qualified practitioners.

To the Editor of "The Medical Press and Circular."

SIR,—The following advertisement I cut out of the *Daily Telegraph* columns of last Wednesday:—

"TO CHEMISTS and MEDICAL MEN (sine diploma).—A registered SURGEON, of experience, will CO-OPERATE with either of the above for establishing a PRACTICE in a populous district.—Address Alpha, Post office, Southampton road, N.W."

Who can this Surgeon of *Experience* be who is thus seeking to lower his Profession? Some quack perhaps. The Pamphlet also enclosed has been extensively circulated around here, and people seeing no names of medical men to it, generally give it a trial. One of the gentlemen named, I see by the Directory, lives at the address given, and although he is styled Surgeon, he is only *L.S.A.* If he has given this testimonial I think he should be called upon for an explanation, and if not, he should prosecute.

Yours truly,

Aug. 13, 1870. VERITAS.

"GREENWICH UNION."

To the Editor of "The Medical Press and Circular."

SIR,—I read with combined feelings of admiration and indignation your remarks relative to the rscent election of a Workhouse Medical Officer by the Guardians of the above Union—admiration at the candid manner in which you set forth the whole affair, and indignation that there is not some check whereby Boards of Guardians could be prevented from misleading the Profession. Can the Guardians of the Greenwich Union for one moment imagine that the public will believe that an M.D. of the University of Edinburgh of 1869 was the best-fitted candidate for the appointment out of forty applicants? If so, I fear you must be in error as to the diplomas, testimonials, and experience of the others.

A short communication from that Board as to the grounds on which the election was made would, I should think, be very acceptable to the unsuccessful candidates.

I am, Sir, your obedient servant,

Plymouth, August 13th, 1870. JOHN TURNER, M.R.C.S.

To the Editor of "The Medical Press and Circular."

SIR,—You seem to forget that the Board of Guardians at Greenwich may be a very liberal Board indeed. Seeing the miserable salaries that are offered by many Boards of Guardians for the services of medical men, £300 per annum is not to be sneezed at.

I would not wonder but that the successful candidate was the *most recently qualified* of the forty who applied, accordingly, he in a greater degree requires to gain experience, and with a large spirit of liberality the Guardians of the Greenwich Union not only give him a fair remuneration for his services, but afford him the sick wards of the workhouse as a field for gaining practical experience.

Whether so important an office should be entrusted to the sole charge of a medical gentleman of only one year's standing is, I believe, a question which the Guardians are alone empowered to decide.

If the rumour regarding canvassing be correct, I think the case is one into which the Poor-law Board should make inquiries; if it be incorrect, and if none of the Guardians were canvassed, either directly or indirectly (in the broad sense of the term), they might, I consider, without any injury to their own dignity, direct their clerk to write to the MEDICAL PRESS AND CIRCULAR, denying the rumour, and I feel certain you would gladly insert their letter.

I am, Sir, your most obedient servant,

Aug. 12, 1870. RUSTICUS.

STRYCHNINE IN FATTY DEGENERATION OF THE HEART.

To the Editor of "The Medical Press and Circular."

SIR,—In reply to the query of your correspondent, Surgeon Smythe, respecting the after treatment to be adopted in those cases of fatty degeneration of the heart wherein liquor strychnine was exhibited, I beg to remind him or refer him back to the communication itself on the face of which it is stated, that I combined the iodide of ammonium with strychnine in the hope that this drug would act as an absorbent, which I believe it did.

I consider the continued employment of this medicine—the iodide of ammonium—in mixture with some bitter tonic will constitute a judicious treatment after strychnine is fairly pushed in cases of fatty heart, and that it will be found more satisfactory in its effects and more suitable generally than liquor potassæ.

I hope this communication conveys the information your respected correspondent seeks and requires from me, and should it not I shall be happy to write to him upon his addressing me.

Your obedient servant,

J. WARING-CURRAN.

Osman House, Sutton, Notts, August 10th, 1870.

FEES FOR SUCCESSFUL VACCINATIONS.

To the Editor of the "Medical Press and Circular."

SIR,—I read in the *Lancet*, page 135, July 23, 1870, that the Lords of Privy Council have awarded gratuities of £8 4s. 8d. to Mr. Thos. C. Roberts, Tattershall district, Horncastle Union, and to Messrs. Kelly and Clapperton, of Market Deeping, Lincolnshire, £6 14s. for successful vaccination. On August 10th, the MEDICAL PRESS chronicles other similar instances. Now, these gentlemen are public vaccinators and paid at a rate much higher than we are paid in Ireland, and, I have no doubt, earn their money well; but I do not see why similar rewards are withheld from us in this country. I can show, and I am sure many others can do the same, that every child born since the 1st of January, 1864, in my district remaining resident and alive at six months of age, has been vaccinated, and that fully 90 per cent. of these has three good cicatrixes. I doubt if any union or district in England can show more perfect work than that, and yet I get no gratuity.

Portlaw. JAS. MARTIN.

FREE TRADE IN SURGICAL INSTRUMENTS.

To the Editor of "The Medical Press and Circular."

SIR,—I have read Mr. Atherton's plea in your last and crave leave to reply. I entirely agree with the spirit of your remarks and look upon the President of the Notts Chemists' Association as desiring to levy a toll on the passage of articles needed by general practitioners, from wholesale depots to their surgeries. He gives up instruments to free trade, but wants to tax my plaisters, lint, bottles, pill-boxes, and numberless other articles.

Now, Sir, what are plaisters and lint to chemists in comparison with surgeons and apothecaries! I use more bottles and pill-boxes than any chemist near me, and yet forsooth in times of "free trade," I am to be deprived of buying except through a local tradesman who will "stick it on" because I am a Professional and fully occupied, and who will use the knowledge he gets from me to snare my patients to his counter for various things, and, perhaps, for "pills and draught," without my advice.

No, Sir, I never will deal with a local chemist, and if Maw is to be frightened out of trading with me I will buy my bottles, boxes, &c. at various depots as I have done for years.

I am, &c,

APOTHECARY.

The Medical Press & Circular.

ON SNUFF-TAKING:

ITS UTILITY IN PREVENTING BRONCHITIS AND CONSUMPTION.

By John C. Murray, M.D., F.A.S.L.

The literature of snuff-taking is remarkably meagre. During the classical era of English history, the practice is often spoken of as an established usage of society, especially among ladies and gentlemen of *ton*. At the present period it is the custom only of individuals who are conceived to be in arrears of the times, consequently it is thought a dirty, disgusting, and pernicious habit, which, from having nothing whatever to recommend it, must cease in two or three generations. Why, then, come to the rescue? Why aid in redeeming this bad habit from well-merited disuetude.

Such is apparently the sentiment of authors with regard to this subject. From strong feelings of conviction, I beg leave to break through the reticence which has for a long time been observed upon this now unfashionable foible, having something new to advance in its favour, which, for reasons to be by-and-bye submitted, cannot be said equally of tobacco-chewing and smoking, viz., that an *habitual snuffer seldom, I had almost said never, dies of consumption.* This remarkable proposition I have suggested to not less than 500 snuff-takers, many of whom are in the Medical Profession, and all that I have hitherto learned has only strengthened my conviction in the truth of my theorem. One Medical friend, himself a snuffer, writes "with regard to snuff I know no facts on the subject, but can see nothing, physiologically or pathologically speaking, in the use of snuff, which can render it beneficial in or prophylactic of phthisis." Since snuff has been taken out of the list of remedies, and become an article of luxury, it is difficult to see how it can so act, and for belief requires observation. Another gentleman, partial to the same weakness, writing from the snuff-consuming county of Lancashire, having given my affirmation his earnest attention for six months, was at last enabled to bring forward a case of a snuff-taker succumbing to consumption. As he was indefatigable in his search, and had excellent opportunities for observation, I look upon his single case as only confirmatory of the rule, especially as circumstances were against the patient. A correspondent from Dumfries writes:—"Since you first bruited your singular idea about snuff, I have interested myself to find whether there is anything in it; the result is, I have frequently observed that those who snuff are ruddy, look, and are, strong; on the contrary, that smokers frequently are pale, thin, and cachectic." He also gives it as his opinion, "that phthisis is much more prevalent in this neighbourhood since smoking took the place of snuffing. The average quantity consumed by those still addicted to the practice of snuff-taking is two ounces per week, but only one person carries a box now for ten in my grandfather's time, the revenue being, however, more than made up by the extraordinary extension of smoking." Since the receipt of this letter, I have daily observed the ruddy appearance of snuffers, and recently, as a tedious case, it was singularly corroborated by an old lady of charming complexion and full contour, who, between her sniffs, and without my introducing the subject, said "it is surprising what a good colour snuffers generally have." This lady had been recommended to snuff by the late Dr. Bleasby for continuous pain in the back of her head and weakness in the eyes, ailments which she told me she had not suffered from since adopting the remedy. A Liverpool surgeon, after giving the question his best attention, said he "could not name a case of a snuffer who was phthisical, but he might say he had observed that those who partook of snuff, as a rule, attained old age." Upon incidentally stating my assumption to a very intelligent gentleman connected with the Profession, he said he "could not confute it; on the contrary, he was the only one in his father's family that consumption had spared, and, at the same time, the only one who took snuff. One of his brothers, who regaled his nostrils with an occasional pinch, survived

the longest." A similar concurrence was lately seen by myself, that of a well-to-do family, some members of which have already died of consumption—of those who remain only one, and he not the eldest, snuffs and is strong. Many of those referred to could not, at the moment, remember any instance of a person fond of snuff dying of phthisis. The idea had never occurred to them, but should a case present itself in their practice they would let me know. From a considerable number of these I have since received letters stating that, after observation and inquiries, they are inclined to believe that there is more truth in my theory than at first sight appeared to them, for they have not as yet been able to oppugn it.

The *Tobacco Trade Review* of April 9th, 1870, in a leader replying to a letter of mine, asking the editor or any of his readers for corroborative or adverse facts in point, says, "We have failed, so far, to trace a single instance in support of Dr. Murray's views, that regular snuffers never die of consumption, because we have not found an instance of a person of a consumptive tendency who could take snuff under any circumstances." In addition, I am led and inclined to believe that the capability or inclination for snuff-taking may prevent and check tubercle in the lungs, indicate its absence, or, if present, a tendency to recovery in the same way that being able to eat fat is known to do. The editor also states in his reply, "The taking of snuff excites two sensibilities, the sensibility of smell and the sensibility of taste. To a regular snuffer, snuff is really food, and he derives the same gratification from its use that he would from taking food." Everyone will coincide with the editor in this, who has been in the habit of indulging his olfactories.

I have *not* had an instance in my own practice of any one who enjoyed his snuff falling a victim to phthisis pulmonalis, but, in contradistinction to this negative testimony, I *have* had six cases of recovery from phthisis after the exhibition of its most reliable signs and symptoms, some of them even in the second stage, one each in the years 1860-62-64-65-66-69. The first three commenced of their own accord to snuff with avidity, as if they had been favoured with a special revelation upon the subject, or, as frequently happens in medicine, experienced a longing for that which would benefit them. In the fourth and fifth cases I advised its use. The last had been a light snuffer; he is now more intemperate. Five of the number are strong and active members of society, bearing their share of the fatigues and exposures of busy life, and evincing remarkable stamina—the sixth is following his avocations, and daily gaining strength. Three other patients, whose lungs for some time have not been in a satisfactory state, have during the current year purchased tabatieres, and are giving the "dusty god" a trial. The latest bulletin is, "they are doing as well as can be expected." Further, I have attended some, and know others, who have thrown off the consumptive malaise, after acquiring a taste for snuff, from taking occasional pinches from the box on the desk before them, in the case of a clerk, or, *pro bono publico*, in that of a traveller, but who do not wear a reservatory, and, consequently, may not be entitled to primary rank.

I have been guarded in recommending the adoption of a practice now so generally disliked, and so enslaving as that of snuff-taking, but during the last three years I have had many opportunities of observing that, in hopeless cases of consumption, patients could not stand snuff; on the other hand, when they were able to tolerate it, they have recovered from that attack, although it may be premature to say that they are permanently restored to health. It is with great diffidence, and only after due consideration, that I venture to moot the pungent statement coronal to this chapter. The individuals who have tried snuffing through my almost reluctant advice are too few, the practice of one medical man is too limited, and I am aware that it is no novelty for a person to have such a bias for anything of his own conception, as to be but an indifferent guide to others. However, having now the honour of broaching the question, I trust our friends from Scotland, and the great snuffing centres of Lancashire and Yorkshire, will avail themselves of the opportunities which are so open to them, and corroborate or condemn the tenet that snuff-taking is nearly incompatible with, and, in some degree, preventative of consumption. Some more facts are desirable, seeing that a patient may recover from a number of attacks of phthisis, only to sink from one at last, and that other, and more orthodox, treatment was pursued in each of my cases.

It being difficult, in this smoking age, to collate sufficient evidence to be quite unimpeachable that snuff is curative of phthisis, I will, therefore, content myself with showing that the habit in question is, in some degree, preventative of consumption and its frequent concomitant bronchitis. By titillating the lining membrane of the nostrils, snuff acts as a powerful derivative and counter-irritant, and the mucous discharge which follows its use will tend to preserve the more important and susceptible pulmonary mucous membrane from evil. The sneezing which succeeds the unaccustomed application of the errhine, or agitates even an old and seasoned nose, when a new titillant is tried, and the cough which is induced when, by chance, some of the lighter particles get into the throat, may be of some avail in effecting the elimination of albumenoid matter (the precursor of tubercle) from the lungs, ere it has had time to fill the air-cells and minute bronchi, and coagulate, in like manner, as sea-sickness is believed to do. The majority of medical men, when recovering from a common cold, will take a pinch in order to "speed the going guest." If good to expedite the departure of a cold, I have no hesitation in affirming that it will be better still as an expedient in altogether preventing the catarrh, *e. g.*, if, when on a journey, you experience a succession of chills, in due time you may expect an attack of bronchitis, an infiltration of pneumonic, or tubercular plasma, or illness in some other form, each tending to reduce the powers of life, and, consequently, liable to set up consumption in those predisposed. If a sufferer, you relieve the discomfort by having recourse to your box, from which after gently tapping you proceed to take a pinch of the agreeable, and in this case useful, stimulant. The exercise, slight though it be, the engrossed attention, the pleasurable sensation, the diaphoresis, and the smart glow which is at once diffused throughout your system by the pungent divertissement, the generally welcome conversation which the acceptance or refusal of a proffered sneeze is likely to elicit, materially serve to ward off, and make you forget, the dangerous chill. Should it return, nothing is more easy than to repeat the excitation.

It may be said that a cigar, a pipe, or some alcoholic refreshment, would be more potent and effectual as a preventative of cold, but snuff is emphatically a stimulant. Tobacco, although useful, is more strictly a sedative; besides, smoking is only practicable to the initiated, and, where permitted. Wines or spirits—although excellent as a prophylactic of catarrh, when only taken medicinally, upon an occasion like the one suggested—are apt to unhinge for the day's business, and their frequent use has a tendency to engender disease of the liver, kidneys, blood-vessels, brain, nervous exhaustion, indigestion, and consumption itself.

I do not agree with those who say that a practised snuffer ceases to sternutate; that he is too inured to the sternutant for the blunted olfactory nerves to react. Such cannot be the case until he has exhausted the 50 (more or less) kinds of the pulvil. I have seen men, who have known nose-hunger for 50 years, get three hearty sneezes out of a new kind of naso-palatine food. But even if the connoisseur has been accustomed to variety, and his run of snuffs have at least failed to be errhine sternutative, or even exciting, he has reason to be grateful. He must be thirty-eight years of age, and whatever else he may die of, it will scarcely be true tubercular consumption of the lungs.

Since the foregoing was written I find that in France, where tobacco is grown under State supervision, and manu-

factured by Government, in nearly equal proportions, into tobacco, cigars, and snuff, the health of the ouvriers has been made the subject of official report, of which the following summary may not inaptly be given here. The workmen in tobacco factories of the State do not suffer from any disease which the tobacco could be imagined to occasion; on the contrary, the employes seem to have had an immunity from typhus fever, as at Lyons; from dysentery, as at Morlaix; from miliary fever, as at Tonneins; and from cholera everywhere. The majority of physicians to the state factories believe employment among tobacco to be instrumental in preventing consumption in the lungs, and may even restore consumptives to health. As the paternal Government of France have taken up this question, I hope at some future time to be enabled to give the result of extensive observations upon this important point. Having made inquiries of many manufacturers, and surgeons in charge of tobacco factories in England, I find that, as far as they could say, the opinion of M. Parent Duchatelet and his medical confreres is borne out in this country; but, as tobacco hands are a migatory class of men, little reliance can be put in English statistics.

HYPODERMIC INJECTION OF MORPHIA IN TEDIOUS LABOUR FROM RIGID OS UTERI.

By Chas. W. Shaw, L.K. & Q.C.P.

Seeing, some short time ago, in an American Medical Journal, an account of the successful treatment of several cases of rigid os by means of morphia internally administered, and being favourably impressed with the arguments there used, I determined, if I should have an opportunity, to put its utility to the test.

The first case in which I saw an occasion for its profitable use was a *primipara*, æt. thirty, of sanguine temperament, who had been forty-eight hours in labour, membranes having ruptured some four days previously, and the os not larger than a florin, thin and undilatable. Having suffered so much, and being in a very nervous state, she was desirous of my remaining with her. I waited in the house for about six hours, and when the pains, although strong and frequent, were not producing the desired effect on the os, I determined to try the morphia treatment, more desirous of obtaining sleep for my patient than of hastening the labour. Having been called in unexpectedly to see this lady when I was out driving, and unprovided with any of the usual supplies, and being some six miles from any place where I could obtain a preparation of opium, I was rather nonplussed at first; but, fortunately, seeing some paregoric elixir, I gave her half an ounce, which, for twenty minutes or half an hour, appeared to produce no sensible effect, except diminishing the severity of the pains, though they continued as frequent and as long as before, till my patient called me, and said she thought the child was nearly born. I found the head pressing on the perineum, and in a few minutes delivery was accomplished—the placenta came away naturally, and everything went on favourably. The time from the administration of the paregoric till the conclusion of the labour was forty-five minutes.

On the 2nd July I was asked to visit another lady, æt. twenty-three, also *primipara*, who had been strong in strong labour thirty-six hours. At the time of my visit—three o'clock—I found the head presenting, and the os not larger than a shilling. I advised waiting, and left. Was sent for at five a.m. next morning, when I found everything almost *in statu quo*, but my patient extremely exhausted. Having a syringe in my pocket, at six a.m. I injected 0·25 gr. of morphia, and had the pleasure of finding the os dilating rapidly, and labour completed favourably in about three hours from the time the morphia was used.

Again, on the 9th August, at one a.m., I was called to visit another case, æt. thirty-five, who, although mother of three children, had not been pregnant for twelve years. She had been in labour for more than twenty-four hours; and, as all her previous confinements had been easy and rapid, she was considerably alarmed as to the result this time. Finding the membranes sound, with the pains moderate, and the os barely dilated, I left. Seeing her in the course of the evening, when I found slight change. Next morning, at six a.m., I was sent for, membranes having ruptured from the violence of the pains; but the os not larger than half-a-crown. At this time she also complained of pain a little to the right of the umbilicus, where there seemed to be a thickening of the wall of the uterus. Partly to relieve the pain, which she complained of most bitterly, but chiefly to expedite matters, I injected 0·40 gr. of morphia, and in the course of two hours the child was born. The placenta was adherent just in the place where the hardness was perceptible after the escape of the liquor ammonia.

I think the moderate use of any of the preparations of opium, either internally or hypodermically, would be productive of the happiest results in those cases where the rigidity of the os proceeds from an extreme amount of nervous irritability.

ON THE FORCIBLE INTROSPECTION OF WOMEN BY GOVERNMENTS.*

By Charles Bell Taylor, M.D., F.R.C.S.,

Surgeon to the Midland Eye Infirmary.

Dr. Taylor first questioned the right of Government to forcibly introspect women. He admitted the propriety of State interference in times of pestilence, or of great public danger when people could not help themselves, and suffered from no fault of their own; but even in such cases three essentials were needed—first, the necessity for interference must be undoubted; secondly, the law must be limited to the shortest possible period; and, above all, it must be impartially applied. He pointed out that the living a loose life and catching disease was a voluntary act, for which no citizen has any right to call on the State to protect him. He asserted that there is no adequate necessity in this country for any legislation on the subject of venereal diseases, because these diseases have for years, prior to the enactment of the Contagious Diseases Acts, been declining in extent and virulence, both in the Army and out of it; also, because there is only one disease of venereal origin—true syphilis—that affects the constitution, or can on any pretence be considered a matter of State concern; because true syphilis constitutes but a small fractional proportion of the mass of cases which are classed under this head; and because, in the language of Mr. Simon, in an enormous majority of cases this worst form of venereal disease is not of more than transient importance to the person attacked; because, also, the milder forms of venereal maladies (nine-tenths at least) though unimportant in themselves, are still great checks upon incontinence, and, consequently, the means of saving thousands from the more serious malady. Dr. Taylor dwelt strongly on the injustice of the Acts as applied to women only, as though they had spontaneously generated an affection which must have been previously communicated by a man. There was abundant evidence to show that men (notably soldiers and sailors), are equal, if not greater, sinners. The Doctor questioned the wisdom of State interference with prostitution as a trade with a view to supply men with a good article for their money. There could be no trade without a buyer, and if the trade was immoral, buyer and seller were equally guilty, nor could Government virtually or actually licence it without being implicated in its immorality. He asked what would be said if a deputation of prostitutes waited on Parliament to demand despotic and

* Abstract of a Paper read at the meeting of the British Medical Association, Newcastle-on-Tyne, August, 1870.

indecent laws against men only, on the ground that they communicated disease to them and their children?

After proving by quotations from Parliamentary evidence that modest women were grossly interfered with by the police employed to enforce the Act; also that milliners, dressmakers, servant girls, and labourers' wives, were classed as prostitutes for the purpose of the Act; and that one Parliamentary witness had declared that the Act would never succeed if it were confined solely to those who got their living by prostitution; Dr. Taylor proceeded to state that the means proposed are sure to fail in the attainment of their object—1st. Because absolutely healthy women, by mediate contagion, communicate infection; 2. Because the examination cannot be carried out in a large proportion of cases; 3. Because it is impossible to distinguish numerous affections to which most respectable women are subject from venereal diseases; 4. Because the women examined are exposed to great danger of infection from contaminated instruments; 5. Because the examination and restriction of one sex only, for a disease common to and propagated by both sexes, is not only a cruel injustice, but a delusion and a snare; 6. Because the system calls into existence, and fosters, a numerous class of clandestine prostitutes, who, from fear of detection, conceal their diseases, and become permanent sources of infection; 7. Because true syphilis can so rarely be detected in the female, that the examination, by giving a false security, offers a direct inducement to thousands (especially married men) to contract disease. Dr. Taylor quoted a mass of evidence in support of his sanitary objections to the Act. He referred to the statistical table of MM. Puche and Fournier, which show that of 873 men who contracted syphilis in Paris, 625 owed this worst form of infection to intercourse with registered and regularly inspected women. He also called attention to the following statement from M. Lecour, the head of the Parisian police employed in carrying out these regulations—"We may fairly consider the 9,500 patients, who are treated in the hospitals, as representing certainly not more than one-fifth of the venereal patients in Paris. We thus reach a total number of 47,500, a formidable number, although it is probably *below the truth.*" Dr. Taylor contrasted this statement with the fact that in London, with a population double that of Paris, we find, from the careful investigation of Mr. Wagstaffe, and the report of the Medical Officer of the Privy Council, that among a poor population of a million and a half there are only 455 cases of syphilis, a proportion of which, as stated by Mr. Simon, cannot be held so large as to call for exceptional action on the part of the Government. Dr. Taylor quoted statistics compiled by Dr. Balfour, showing that venereal diseases in the Army were declining at a rapid and satisfactory rate previous to the passing of the Act, and that since the Act was put in force, the decline had in no case been so great as formerly, but that at certain stations there had even been an increase of disease. Similar evidence came from Holland, Bengal, and Bombay, to prove that interference for the prevention of venereal maladies made matters worse instead of better. Finally, Dr. Taylor stated that other means entirely unobjectionable, Christian, merciful, and in full accord with the free spirit of English institutions, would suffice to check the spread of disease, in proof of which he gave evidence to show that women are most eager to apply to hospitals for treatment when diseased; and asserted that there was no need whatever for police spies, disgusting periodical examinations of healthy women, or the infamous degradation of the sex generally, which is too surely accomplished by the present law.

From simple cholera and choleraic diarrhœa twenty-five deaths were registered last week in London. This shows a marked decline on last week's returns. During the week there were eleven deaths from variola and 118 from scarlatina.

CLINICAL MEMORANDA.

CIRRHOSIS OF LIVER; VIOLENT PAINS IN EPIGASTRIUM; DIMINISHED HEPATIC DULNESS; JAUNDICE.

Reported by John W. Martin., M.D., M.Ch.

Case.—Michael Meehan, æt. about fifty, shoemaker. Notes taken July 10th, 1870.

History.—Occupation sedentary. As a young man was very fond of dram drinking, drunk freely, and "racked" himself to a great extent. About ten years ago gave up drinking, and since then has been very temperate. Circumstances impoverished. Frequently sits up all night at work. Drinks freely of strong tea. General appearance that of a pale, ill-nourished, unhealthy-looking man. For some time previous to the date on which these notes were taken, he was complaining of pain and uneasiness in the epigastrium, and constipated bowels. Treatment not relieving him, a closer examination elicited the following—

Symptoms.—Violent pain felt at the epigastrium, with a feeling of oppression. Abnormal resonance on percussion over area of præcordial dulness. First sound of the heart exaggerated, giving the idea of a "click;" no friction sounds, or endocardial bruit. Exaggerated resonance on percussion over the lungs. Respiratory sounds normal. *Hepatic dulness* diminished 2¼ inches vertically, and all over the area of dulness abnormal resonance most marked. No special tenderness or pressure complained of over the region of liver or gall bladder. Palpation revealed nothing. Bowels been always very constipated, frequently not being moved for a week together, and then the motions are hard and scybalous, and very dark in colour. Frequently suffers from headaches, from which he gets no relief until he has vomited a fluid, which he compared to "the skimmings of mutton broth." Tongue weak, furred, and indented. Anorexia, restlessness, and inability to sleep.

Treatment.—For some days previous to date of notes, had frequent turpentine stupes and sinapisms applied over the epigastrium, and was taking aperients, tonics, and anodynes. On the evening of the 9th, one-third of a grain of solution of muriate of morphia was injected into the right arm at the insertion of the deltoid; felt a warm, pleasant glow, and general tranquillity for an hour subsequent to operation. Again became restless, was attacked with pain, and spent a bad night. Early on the morning of the 10th, a dose of Battley's sedative, ʒss., was given, and at half-past ten o'clock, finding him no better, a blister, 4 + 3, was applied to epigastrium, to be left on for nine hours. At nine o'clock in the evening felt better; pain greatly diminished; blister rose well; tongue clean and firmer looking; felt inclined to take some bread and milk. Again injected morphia, quarter of a grain

July 11th.—Slept quietly and well until two o'clock—after that was somewhat restless. *No pain* to-day. Eyes jaundiced. Urine deep saffron yellow. Presence of bile shown by the reaction on testing with nitric acid, and the characteristic stain on steeping a piece of linen in it. No sugar or albumen. The discharge from the blistered surface also imparted the characteristic bile stain to linen. There has been no change in the dark colour of his stools.

July 12th.—Improved. Ordered nitro-muriatic acid mixture. Jaundice clearing.

July 14th.—Convalescent.

Remarks.—In the above case there was evidently that condition of liver known as "dram drinker's liver," cirrhosis. Both my father and self felt some hesitation in determining to what we were to ascribe the violent pain felt at the epigastrium; the probabilities were in favour of its being due to the passage of a gall-stone, but against this supposition were the following:—

1st.—The pain did not come or go abruptly.

2nd.—Seat of pain, not that usual in cases of gall-stone.

3rd.—No gall-stones have been detected in the motions since; though they have been carefully washed and strained through muslin.

In the above case, also, we have a good illustration of the use, however empirical, of counter-irritation; for, undoubtedly, relief *gradually* followed the application of the blisters, though some are unable to explain the *modus operandi* of counter-irritation, and, therefore, are sceptical of the benefits to be derived from its use. I am sure there are few men of large experience who will not agree with me, that its abandonment as a therapeutical agent would be most unjustifiable.

Transactions of Societies.

BRITISH MEDICAL ASSOCIATION.

In our last number we gave a report of the general meetings. We now furnish a condensed account of the proceedings of the different sections:—

Section A.—Medicine.

Dr. Embleton, president, in opening the proceedings, delivered a brief inaugural address, in which he welcomed the meeting to Newcastle, and made allusion to some of the characteristics of the town and neighbourhood. He afterwards proceeded to state that there had been a school of medicine existing in Newcastle since 1834; and the Newcastle Infirmary enjoyed a reputation similar to that of the West Riding—the Leeds Infirmary. Among the first to require that clinical teaching, which had now become imperative upon all medical regulating and licensing bodies, was the University of Durham, in conjunction with the College of Medicine. At this time of change and progress, they endeavoured to progress with the age, and were persuaded that this great gathering would give them a powerful impulse and advance. He then referred to the discovery of the successful application of anæsthetical remedies, the intricate researches into the origin of life, and the propagation of zymotic diseases, and the wonderful rapidity and extent of the advance of medical knowlege. Much had already been achieved, but much yet remained to be done, and he was sure that the present meeting would not be less successful than those that had preceded it. Dr. Paget moved, and it was seconded by Dr. J. C. Murray, that a vote of thanks should be accorded to the President for his address—carried. Dr. D. Embleton read a paper "On the Shoulder-tip Pain in Liver Diseases," Dr. Howell, F.R.C.S., read a paper "On the Treatment of Paralysis;" Dr. A. E. Sansom read a paper "On the Sulpho-carbolates, and the Antiseptic Method in Medicine;" and Dr. Wiltshire read a paper by Dr. George Oliver, on the "Therapeutics of the Seaside."

This terminated the first sitting.

On the second day, Dr. Henry Barnes, Carlisle, in the absence of the President, took the chair. Dr. R. Renfrew read a paper on "The Treatment of Scarlet Fever," on which there was a short discussion. Dr. Murray read a paper on "Snuffing: Its Utility in Preventing Bronchitis, Consumption, &c." This paper our readers will have the opportunity of judging by our fuller report. The papers of Dr. T. C. Allbut on "Functional Hemiplegia in Child-bearing Women," and Dr. Whitehead on "Mucous Disease," were taken as read.

On the following day this section concluded its business, when Dr. Embleton once more occupied the chair. Dr. Philipson, of Newcastle, read some notes on a case of biliary fistula, which had come under his treatment at the Newcastle Infirmary. A paper entitled "Remarks on the Beneficial Effects of Combination Tonics with Aperients in Chronic Constipation" was read by the Rev. Dr. Bell, M.D. The following papers were taken as read:—"Syphilis in Physicians' Practice," by C. R. Drysdale, M.D. "The Case of a Man who had a Vesicular Eruption in the Abdomen, which discharged at times great quantities of a Chylous Fluid," by Mr. Roberts, M.D., of Manchester.

Section B.—Surgery.

In the absence of the President and the Vice-President, Mr. Henry Power took the chair, and, without any introductory remarks, called upon Mr. William Adams to read his paper "On the Subcutaneous Division of the Neck of the Thigh-bone, as compared with other operations for rectifying extreme distortion at the hip-joint with bony ankylosis." Mr. Adams advocated the subcutaneous division of the neck of the thigh-bone, and detailed a successful case which he had made upon a man in London. Mr. F. Jordan made a few remarks upon a portion of the paper. Dr. John Russell, of Newcastle, read a paper on "A case of Femoral Aneurism cured by rapid pressure in the Newcastle Infirmary." Dr. Russell, at the conclusion of the paper, said that the treatment of aneurism by rapid pressure was not receiving that attention in other parts of the kingdom that it was in Newcastle, where several cases had been successfully treated. Newcastle, he said, was the birthplace of the rapid pressure treatment, which he recommended in contra-distinction to slow detriment. Mr. Lawson Tait considered that the Newcastle school could scarcely claim as being the first to introduce the rapid pressure treatment, and thought that, if any school was entitled to the claim, it was Dublin. He differed from Dr. Russell that this particular mode was not practised by medical men in other parts of the country, and quoted several cases which he had had under his notice. Dr. Russell, with all deference to Mr. Lawson Tait, still adhered to his statement that Newcastle was the birthplace of the rapid pressure treatment. Dr. Gregson and the Chairman also took part in the discussion. The Secretary read a paper by J. C. Gibb, M.D., Newcastle, entitled "On a successful case of Ligature of the Superficial Femoral Artery in Popliteal Aneurism, on Lister's Plan." A paper "On a New Form of Elevation for Depressed Cranium in Childhood," by Frederick Waterhouse, M.R.C.S., was read by the Secretary. Mr. Anthony Bell, M.R.C.S., Newcastle, read a pamphlet "On Notes of a Case of Epilepsy of sixteen years' duration from Parietal Depression of Cranium: Trephining: Recovery." The Chairman, at the conclusion of the paper, and after putting several questions to the patient, who was present, remarked that the treatment had been extremely satisfactory in its results. Mr. R. Walker, L.R.C.P.Ed., read a paper entitled "Operation for the relief of Contracted Toe."

On the second day, the chair in this section was taken by Dr. K. King, of Hull. Mr. Furneaux Jordan, of Birmingham, read a paper "On the Treatment of Enlarged Cervical Glands." In the discussion that followed, the Chairman, Mr. Hutchinson, Mr. Spencer Watson, Dr. Heath, of Newcastle, and Dr. Wilson took part. Mr. Hutchinson read a paper entitled "On Xanthelasma Palpebrarum as a Symptom of Diathesis." The paper was illustrated by drawings. A paper on "Spermatorrhœa," was read by Mr. W. F. Teevan. Mr. Spencer Watson read two papers "On the use of the Seton in the Treatment of Vascular Ulcers of the Cornea," with illustrated cases and drawings; 2. "Cases of Traumatic Ophthalmitis" Dr. Legat, of South Shields and the Chairman took part in the discussion that followed. Mr. Teevan gave a condensation of his paper on "Twenty Cases of Stone in the Bladder." Dr. Arnison and the Chairman made some remarks on cases upon which they had operated. The Secretary read a paper from Mr. Fairlie Clarke on "Some Rare Forms of Opacity of the Cornea."

At the third meeting, Dr. Heath, of Newcastle, occupied the chair. Dr. Protheroe Smith read a paper on "Diagnosis and Treatment of Tumours and Effusions by means of Exhausting Needle Trocars." Dr. Smith exhibited an apparatus of his own invention, and explained the manner in which it was to be used. A paper "On the Treatment of Hæmorrhoids" was read by Dr. Daniel McLean, of Glasgow. The next paper was by Dr. Heath, of Newcastle, "On the Rapid Treatment of Aneurism." Dr. Gammage, of Bishopwearmouth, and others, took part in a full discussion on this important paper.

Section C.—Physiology.

Dr. Andrew Clark, President, occupied the chair at the first meeting of this section, and delivered an introductory address, in which he said that Medicine is the art of healing, whereby we endeavour to preserve health, cure disease, and alleviate inevitable suffering. Physiology is the science which investigates the conditions or laws of healthy, bodily, and mental life in man. It was the business of medicine to consider health as well as disease, and the consideration of health involves—1st, the regeneration of physical growth and development by means of food, exercise, air, and the like; 2nd, the regulation of mental growth and development by

means of education in its literal and highest sense; 3rd, the conservation of health and energy—the prevention of disease by personal hygiene; and 4th and lastly, not merely physical and mental development as it now exists, but the advance of physical, mental, and moral development of which we believe man in time to be susceptible, through the influence of agencies for ever at work and capable of control. It was only through physiology that medicine could accomplish any or all of these objects, and, in whatever light considered, they are truly the greatest that science can achieve for men. Mr. John Couper read a paper on "The Diagnosis of Astigmatism by the Ophthalmoscope." Dr. Milnes Fothergill, of Leeds, read a paper "On the Preservative Agency of Lowered Vitality," and a discussion followed, in which Professor Bennett of Edinburgh, and several other members took part. Dr. J. A. Bolton, of Leicester, then read a paper entitled "The Naked Man and his Photograph, *in re* the Turkish Bath," which was well received; Professor Bennett, Dr. T. E. Hayden, and others expressed a wish that more certain information should be collected, with a view of ascertaining whether the Turkish bath should be more generally used in medicine.

At the second meeting of this section, Professor T. Hughes Bennett, of Edinburgh, took the chair, in the absence of the President, Dr. A. Clark. Dr. B. W. Richardson read an instructive paper "On Anæsthetics," after which Dr. Elliott, of Carlisle, read a paper entitled "Lobelia as a Poison; evidence from eighteen inquests, with *post-mortem* examinations." After some remarks from Professor Bennett, and Dr. Waters, of Liverpool, Dr. Elliott said he had a volume with him containing a large amount of information with respect to experiments on the lower animals with lobelia, which might form the subject of a second paper that might be prepared and read at some future time. Professor Bennett hoped that Dr. Elliott would prepare such a paper, and he then proposed that the section should meet again punctually at nine o'clock the next morning, when he would demonstrate by experiments on two rabbits that chloral and strychnine were antagonistic poisons. This adjournment was at once agreed to.

At the concluding meeting of this section Dr. Waters presided. Professor Bennett read his "Interim report of committee appointed to investigate the antagonism of strychnine and chloral." He experimented upon two young rabbits purchased for the purpose. He injected into one of the animals a solution containing the 150th part of a grain of strychnine, while to the other he administered in a similar manner a like quantity of strychnine and twelve grains of chloral. The first rabbit speedily displayed great restlessness, and was subject to slight twitching, while the other became remarkably still. Presently the first leaped up and instantly fell into convulsion, expiring within a few minutes afterwards. About the same time, the other one commenced to stagger as if under the influence of intoxicating liquor, and seemed to have been seized with an overpowering drowsiness. A few more minutes elapsed, and it fell upon its side in a deep sleep. The Professor then explained that these rabbits were much younger and lighter than those he usually experimented upon, therefore, he was not sure that the sleeping animal would not ultimately die; but he expected it would wake up in about two hours perfectly well. Dr. McVail read a paper on "Respiratory Mechanics," and Dr. McKendrick read a paper on "Exhibition of a new Barometer by Bergson and Kastaus."

Section D.—Midwifery.

Dr. Robert Barnes presided, and delivered an opening address in this section on the first day. Dr. Henry Bennet read a paper "On the influence of Inflammation in the production of Uterine Displacement." Dr. Renfrew, of Glasgow; Dr. J. H. Aveling, Dr. Martin, from Australia; Dr. Thomas Chambers, and other gentlemen spoke on the subject.—Dr. Tilt then read a paper "On Uterine Pathology and the Change of Life and after the Menopause," which produced an animated discussion, taken part in by the President; Dr. Beatty, of Dublin; Dr. Bennett and others.—Dr. Mellor, of Manchester, proposed a vote of thanks to the two gentlemen who had read papers, and it was agreed to.—Dr. R. Barnes, of London, then spoke on "A Case of Retro-Uterine Hæmatocele," and "A New Operation of Embryotomy by the Wire Ecraseur," and illustrated his lecture by operating on the body of a child.

At the second meeting, Dr. Barnes, the President, in the chair, Dr. Aveling, of Rochester, read a paper "On the Advantages to be derived from curving the Handles of Midwifery forceps," and Dr. Graily Hewitt, of London, papers—"1. On a New Instrument for securing the Pedicle in Ovariotomy;" "2. On Strangulation of the Uterus." The section then adjourned until the morning.

At the concluding meeting, Dr. Barnes again presiding, Papers were read by Dr. Smith "On the Pelvic Band;" Dr. H. Miller, "On the Diet of Parturient Women;" and Dr. James Boyd, "On a case of Puerperal Convulsions successfully treated by Chloroform," &c. Dr. Keiller exhibited various instruments.

Section E.—Public Medicine.

At the first meeting of this section, Dr. W. H. Rumsey, Cheltenham, the President, delivered an inaugural address, in which he expressed an opinion that the Profession sustained a loss in the rejection of the late Bill; condemned the agitation against the Contagious Diseases Acts; and alluded to the interest in public health displayed by the late Charles Dickens. Dr. Arthur Ransom, of Manchester, read a paper "On the Registration of Disease, and Meteorology in Manchester and Salford during the ten years 1861-70." The paper, which was an ably written one, showed the rise and fall of disease in the above districts for the past ten years, and at its conclusion, Professor Stokes, of Dublin, testified to its merits, and moved a vote of thanks to the author.—G. H. Phillipson, M.A., M.D., next read a paper "On the Health and Meteorology of Newcastle and Gateshead during 1868 and 1869." The purport of this paper was to show the respective number of deaths in the two boroughs during 1868 and 1869, from what cause they occurred, and the increase and decrease in the respective diseases. During last year, the paper stated, no cases of small-pox occurred in the towns, whilst in the previous year a large number of deaths occurred from the disease. In 1868, 728 deaths took place, and in 1869, 736, showing an increase of eight during the latter year. The paper concluded by stating that the Medical Association of Northumberland and Durham would not after the present year continue to publish the registration of deaths in the districts in consequence of the decrease of the funds of the Society.—The President thought that the authorities ought to publish the registration of deaths, and not to leave it to an individual society.—Dr. Stewart, of London, also spoke on the advisability of the public registration of deaths, and brought forward many arguments in favour of his views.—The next paper read was by Mr. Armstrong Leonard, of South Shields, on "The Difficulties in applying Sanitary Laws." This paper spoke of the unhealthiness of South Shields, from impure air arising from smoke and noxious vapours, causing respiring impediments and respiration imperfectly performed. The paper stated that the sanitary laws against nuisances would remain a dead letter so long as they remained under the administration of local authorities, because most of them were interested in such matters, and would deal as lightly as possible in cases that affected themselves.—Dr. Stewart remarked that smoke could be completely consumed without damaging the manufactories, and also agreed with Mr. Armstrong, that so long as the sanitary laws remained in the hands of persons whose interest it was to evade the law, it would not be carried out. He thought the administration of the laws should be in the hands of disinterested persons, who would compel the offenders to attend to the sanitary regulations.—The President suggested that a resolution should be passed, based on Mr. Armstrong's paper, and presented to the general body of the association. He remarked that the above questions would be considered by the Commission on which his friend, Dr. Stokes, was sitting, as to the means whereby the produce of smoke and alkaline vapours might be prevented.—Mr. Armstrong then moved the adoption of the following resolution:—"That, in future sanitary legislation, the smoke nuisance, and other gaseous pollutions of the atmosphere, may be dealt with by compulsory measures, to be carried out by authorities independent of the district, and instructed by competent inspectors unfettered by local interest and feeling."—Dr. Robinson, of Gateshead, seconded the motion, which was carried unanimously.

On the second day the learned and indefatigable President again occupied the chair. The first paper was read by Dr. J. W. Eastwood, of Dinsdale Park, near Darlington, and was "On Intemperance, in its Medical and Social Aspects." The gist of the papers was that the extreme opinions often put forward by temperance advocates had retarded the progress of temperance itself, and deplored the apathy of the Medical Profession, with respect to the common use of intoxicating

beverages.—Dr. C. B. Taylor then read his paper "On the Forcible Introspection of Women by Governments." Some discussion resulted, and both sides were supported.—Dr. Johnson remarked that the measure appeared to be considered a primitive measure. He thought it ought not to be looked upon in that light. It was hardly a punishment to cure a person of disease. He agreed with Mr. Taylor about the inadvisability of trusting the work to the police. He had had a good deal to do with the police, and he knew that the less the Profession had to do with them the better. Another point, he thought the lecturer attached less importance to venereal disease than was usually attached to it. His idea was that it was a most serious matter, not only for the persons suffering from it, but for their posterity.—Dr. A. Bell stated that there was one good result to be derived from the Contagious Diseases Acts. In Newcastle they could not go through the streets during the period between the hours of ten and twelve without being molested at every corner, and perhaps some half-dozen other times, by some low prostitute. He had been at Paris for about a week, and while there had occasion to be out at late hours. Yet during the whole of the time he was there he was not once insulted by any of these women, and he never saw a woman who he could say was a prostitute. If the Acts were passed to-morrow in Newcastle, what would be the effect upon the women? They were not so low as they were made out to be in some cases, and he thought three quarters of them would prefer remaining in their houses at night carrying on clandestine prostitution to parading the streets, and thus have to submit themselves to inspection. He did not consider that the Acts would increase the immorality by affording a false security, because, if the temptation were got rid of, so half the sin and immorality ceased. As regards the frightful state the constitution was reduced to by the disease there could be no doubt. They treated the disease in a different manner to what they used to do, and yet they could not visit a skin disease hospital in London without witnessing a most frightful state of things in both women and children. He believed if the Acts merely got rid of the women from the streets, and thereby removed the greater part of the temptation, they ought to be brought into operation. People would not like to go to a house, and ask if it were a house of ill-fame. Besides the dissipated, boisterous strumpets, who drank to excess, there was another class which did not drink much, and he considered that while this class was on the street they were a great temptation to young men.—Dr. Reid stated that the Almighty, in enunciating his commandments from Mount Sinai, used words to the effect that he would visit the sins of the father on the children to the third and fourth generation. He thought in Great Britain, with respect to this special disease, it was carried out. That disease was the means of producing scrofula and other affections. With regard to the opposition given to the Acts by several ladies, he thought they would have done much better to attend to their homely duties than enunciating such nasty things as they did.—The Chairman stated that this was a subject that went to the heart of our social life. A number of statistics, gathered in Manchester, showed results directly opposed to those brought forward by Dr. Taylor. Five women had twenty-five children, fourteen of which were miscarriages, and eleven premature births. Those born prematurely died shortly after birth. These children suffered in consequence of the disease of the mothers. What the women said themselves was that they came to the hospital when they were thoroughly infected. They knew nothing about it—it was often difficult to make out. These women were infected by their husbands. It was high time that something was done to eradicate the disease. — Dr. Stewart said he was in doubt as to whether they should call in the intervention of the police in their endeavour to remedy the pitiful state of matters. When persons in the full possession of all their faculties voluntarily deserted the principles of morality, he thought it would be exceedingly perilous to get a soldier or a policeman to interfere in order to prevent him. Whether they could put a stop to it by legislative enactments was to him a matter of the greatest doubt. What was wanted was greater morality. He did not think that petitioning against the Acts would have much weight. They had been got up in a careless manner, and had done much mischief by bringing such matters before people that otherwise would never have thought of them.—Dr. Armstrong combated the idea that prostitutes had increased in towns where the Acts had been applied. He further stated that it was not common policemen that were to do the work, but a special intelligent corps of men.—Dr. Acland said that the first course to be pursued by those who got up the agitation against the Acts, was not to seek absolutely to remove the law, but to show where it required amending.—Dr. Campbell Black read a paper "On Certain Circumstances which contribute to impede the Progress of Scientific Medicine and Surgery." Dr. Tessier read a paper "On Remarks upon an Epidemic of Intermittent Fever in the Mauritius, during 1866-7-8."

At the concluding meeting, Dr. Rogers read a paper "On Dispensaries and Medical Relief," on which ensued a discussion.—The next paper, "On the Climate of Algeria," was read by Dr. Henry Bennett.—Mr. Topley read a paper "On the Distribution of Disease in the Northern Counties."

Section F.—Psychology.

The President, Professor Laycock, M.D., of Edinburgh, opened this section by an address introductory to the papers which were about to be read, after which he called upon Mr. Thomas Laycock to read a paper "On the Practical and Scientific Investigation of the Relations of Body and Mind;" 2. "Case of Epileptic Chorea of Right Arm." R. H. B. Wickham, L.R.C.P., Ed., then read a paper on a "Case of Rhythmical Chorea of the Right Arm and Palsy of the Leg." A slight discussion followed the reading of these papers, after which the section adjourned.

The Psychological section met again the following day, and proceeded in an omnibus to the Borough Lunatic Asylum. The party were conducted over the Asylum and grounds by Dr. H. Grainger Stewart, the medical officer of the Institution. They then partook of luncheon, after which they returned to town, and with Professor Laycock, M.D., in the chair, the regular business of the section was resumed in the Corporation Committee Room, Town Hall. Dr. H. G. Stewart read a paper "On Syphilitic Insanity," instancing three severe cases which had come under his notice, all of which had many peculiarities in common with each other. The President also described a case of the same disease which had come under his knowledge; and after some discussion, taken part in by Dr. Sankey, of Cheltenham, Dr. Clouston, and Dr. Stanley Haynes, of Laverstock, Salisbury. the President, first addressing a few observations on this form of insanity, proposed a vote of thanks to Dr. Stewart for his paper, which was agreed to.—Dr. G. Clouston then read a paper recommending "The Use of the Thermometer in the Diagnosis and Treatment of Insanity," which was followed by appreciative remarks from Dr. Sankey, Dr. Stewart, and Dr. Needham, of York. The President before leaving the chair decided that the section should meet at nine o'clock the next morning, when an hour and a half would be devoted to an important question, which he would introduce, viz.—"How far Alcoholic Stimulants are Necessary for the Treatment of Ordinary Cases of Delirium Tremens."

At the concluding meeting, the first paper was read by Dr. Sankey, of Cheltenham, "On the Etiology of General Paresis."—The next paper read was by Dr. W. Richardson, on the "Psychological Reading of some of the Phenomena of the Emotions."—The last question introduced was by the President of the section, Professor Laycock, named "How far Alcoholic Stimulants are Necessary for the Treatment of Ordinary Cases of Delirium Tremens."

Literature.

MICROSCOPICAL MANIPULATION.*

The subject-matter of this work formed originally the basis of a course of lectures which were delivered before the Queckett Microscopical Club in the early part of last year. The author has now published them, with additional observations and illustrations, in a very useful 8vo. form of 250 pages as a hand book to students. In this work the author has not trenched upon the ground so well occupied by Drs. Beale, Carpenter, and others, but brings their opinions into juxtaposition with his own, as authorities for the views he himself advances. Mr. Suffolk, in accordance with the title of his book, almost rigidly confines his remarks to the uses of the various instruments employed,

* Microscopical Manipulation. By W. T. Suffolk, F.R.M.S. London: Hy. Gillman.

and their structural peculiarity in scientific research, whilst the chapters on mounting and the preservation of objects will prove very excellent guides to the students of this favourite branch of science. Of the illustrations, especially the plates—which are chiefly the author's own productions—too much cannot be said in praise; they are all lithographed from carefully-finished drawings of objects easily obtainable by the student, and place the author not only high upon the list of microscopists, but also establish for him a claim as an artist of undoubted ability.

In conclusion, we would add that the book is well got up in every particular, and although there is little originality of thought displayed, yet, what there is, is sound; and may be safely and profitably put into the hands of many an advanced student.

THE PARISH LEECH.*

This "Medical Metrical Medley," as the author is pleased to dub the work before us, consists of forty-eight pages of "metrical" matter, and sixty odd pages of "notes and references." The "Leech" is the hero of the former. The author takes him up at the age of sixteen, "when passed the thraldom of a country school;" runs him through a full course of medical study and professional examinations, and does not drop him until long after his suspension by the "board's decree;" and *in transitu* submits him to the punishments ordinarily inflicted by caprice and bad laws on parish doctors. "This time only" shall we accept the author's excuse for an occasional limp in the metre he has selected—namely, want of a "musical ear," and beg of him also to remember the old saying, "Porta nascitur non fit." He, however, deserves much credit for the great industry he has displayed in the collection of "Notes and References." They ought to be in the hands of every medical officer, whilst to medical statists and reformers they will be found invaluable for their diversity, and the sources whence they were obtained, data for most of them being appended.

SPECIAL CORRESPONDENCE.

THE WAR IN FRANCE.

[FROM OUR OWN CORRESPONDENT.]

PARIS, August 15th, 1870.

Were I to write you on any other topic than that of the war you would, I am sure, think that I must hear little of what is going on in this great city. In every hospital the only talk is, what is going on with the Army? How many beds shall we have to furnish for the wounded? The "internes" and "externes" of the hospitals are now few in number, and everyone seems to think only of this deplorable and fatal encounter with the modern conquerors of Europe, the Prussians. For my part, I feel a horror for everything connected with battles, and the wounding and destroying of members of our unfortunate race, so that I retain, I trust, sufficient interest in the question of curing diseases, however slight, to allow me to report to you what is going on out of the fields of butchery, which the ambition of a few, and the mad vainglory of the many, have prepared for so many poor men.

In the first place, then, small-pox is greatly on the decline in Paris. In great measure, I believe, this is attributable to the fact that so many persons have recently been revaccinated, and given up the heifer as a delusion, and contented themselves with matter from healthy infants. The *Assistance Publique*, however, is incurably stupid here. It crowds together the poor hospital patients in small cubic space, and, in addition to this, has, during the whole continuance of the epidemic of small-pox, taken cases of that fell contagion into the ordinary hospitals, although it has feebly attempted to do some little towards segregation of the patients, by devoting an old ramshackle hospital in the Rue de Sévres to this disease, and has sent convalescents to Bicêtre. But you are well aware how far back our French brethren are in questions of hospital hygiene. Let us hope that things will mend.

The year 1870 will again prove that abnegation and devotion are virtues inherent in the Medical Profession; for the past eight months there has reigned an epidemic of variola, which, at Paris, has killed several thousands, and physicians have ceaselessly devoted themselves to their duties, whither, with lancet in hand, they have vaccinated the inhabitants, to render them safe against this formidable malady; or, at the bedside of the patient, they have tried to snatch as many victims as possible from this terrible scourge. Hardly was the war declared than the International Society of Succour to Wounded Soldiers, at the head of which are placed Doctors Nélaton, Chenu, and Lefort, began to employ itself in collecting gifts of all kinds, and form ambulances in the American fashion. Without any resources when it commenced, this Society is now enabled to send to the Rhine several ambulances, each of which has forty horses at its disposal, several tents, containing each twenty-four beds, a number of little tents, and innumerable boxes of linen, besides three hundred beds, with supports for the transport of the wounded beneath the tents. Each ambulance comprehends the following medical staff engaging itself as volunteers:—A chief surgeon, several surgeons and assistant-surgeon, either doctors or hospital "internes," and assistants taken from among the students. It has been calculated that in each battle one ambulance can dress 1,500 to 2,000 wounded men. Some doctors here think and write that the value of the International Society has been greatly exaggerated. It is to be hoped that they will weigh and judge before making up their minds. Let us all give both material and moral encouragement to a truly sublime work, since this society has for its aim to alleviate the sufferings of the soldiers of both armies.

The Strasbourg Medical Society has shown an example we cannot too highly praise and applaud, and has decided that each member should immediately go to work to form a committee with their fellow citizens for succouring the wounded. The aim of these committees should be to found in private houses small temporary hospitals, and to assure the reception of the sick or wounded among the inhabitants of these houses. This society should immediately call on all the Profession in Strasbourg and the adjoining department, and engage their services in helping on the common work, and founding in the different centres of the towns and villages temporary hospitals where sick and convalescents can be taken in. M. Sedillot goes as Surgeon to the Army.

In the New Free Medical School for women, recently founded at Paris by the Empress, there are to be three years of study, with the following provisional programme for the first year:—"The first year shall be principally devoted to the study of the sciences, which are the basis of medicine; natural history, chemistry, physics, studied on their application to the art of medicine, and anatomy. During the first six months pupils will attend the lectures at the Sorbonne for the secondary instruction of young girls, and having for object—1. Elementary notions in physics—Professor: M. Jamin, Member of the Institute. 2. Elementary notions of chemistry—Professor: M. Riche, of the Superior School of Pharmacy. 3. Elementary course of botany—Professor: M. Tieghem, Master of Conferences at the Upper School. 4. Elements of animal anatomy and physiology—Professor: M. Bert, Member of the Faculty of Sciences. 5. Elements of mathematics—Professor: M. Philippon, Secretary of the Faculty of Sciences.

In the second six months students are to study—1. A special course of pharmaceutical and medical chemistry. 2. Spinal lectures on human anatomy and physiology, con-

* The Parish Leech. By a Parish Doctor. London: Nicholls Bros., Great James Street, W.C.

sidered in their relation to medicine, and having principally for their object the functions of digestion, respiration, circulation, and innervation. 3. Elementary lectures on pathology, especially on the diseases peculiar to children, and lectures on hygiene. After this second six months, the students will frequent the hospitals which will be appointed for them. Supplementary conferences and demonstrations will take place by special demonstrators. During the first year, and the following years, those students who desire to practise in any Mahommedan country are to have, each week, three lectures in Turkish or Arabic. At the end of the year there will be examinations for passing into the higher courses. The editor of the *Revue Medicale* truly says that, if women are to become doctors, they ought to pass the same examinations as the men do. He is in favour of suppressing the degree of Officer of Health in order to have equality among all doctors in France, and in the same way he desires that women should take the same rank as men doctors. Miss Garrett and other ladies are, I think, of the same opinion as the professor.

By the way, I omitted to say, in speaking of the International Society, that the uniform of the officers of the ambulances is the naval tunic, waistcoat of blue cloth, called "gilet d'Afrique," trousers of blue cloth, soft boots, white cap, or blue caps with the International red cross. Each ambulance has 40 horses, 12 of which are for the transport of the materials, which comprehend 8 carriages, 17 great tents with their beds, 51 small ones, and innumerable linen chests. The tents are 6 metres broad, and 8 metres long, and contain 24 beds in each. They can be erected in 10 minutes. For the transport of the wounded beneath these tents each ambulance has 300 beds, armed with supports. The expense of one ambulance is said to be, all included, 15,000 francs, £500.

It was said some time ago in the *Journal des Debats* that "more than 900 students of medicine, having 12 inscriptions, that is, three years of study, had inscribed themselves at the Hospital of Val-de-Grâce to serve the Army in campaign, and to take care of the sick and wounded. And, in virtue of a recent decision of the *Faculty of Medicine*, all the young men who are sent to the ambulances are exercised in operative medicine by prosectors under the direction of Doctor Lannelongue. Lectures have also been delivered by Dr. Maurice Raynand and Constantin Paul on the Epidemics of Armies.

From July 31st to 6th August, 1870, there were in Paris 151 deaths from small-pox, 9 from scarlatina, 18 from measles, 26 from typhoid fever, 5 from erysipelas, 42 from bronchitis, 48 from pneumonia, 78 from diarrhœa, 2 from dysentery, 5 from cholera, 6 from diphtheria, 6 from croup, child-bed 5, other causes 725. Total 1,126. We see, then, that the war and small-pox do not go well together. Paris is not so crowded as it was, and I see scarcely any English here.

At a recent sitting of the Academy of Medicine, on the 9th August, the room was almost empty. Everyone asked for news, and spoke about the soldiers. The doctors are great patriots here—thus the eminent academician, Dr. Barth, told how he had wished to engage his son as a volunteer (16½ years of age); but he was found at the Mairie to be too young, so that M. Barth was obliged to content himself by contributing money. M. J. Guerin said that he was putting up 20 beds in his house to nurse the wounded at his own expense, and he was loudly applauded. Then M. Piorry related his experiences, which went as far back as the Peninsular War under Napoleon the First, and the meeting dissolved.

M. Lefort went to the war a fortnight ago. M. Liegois set off a week after, and I am continually meeting with *confrères* who are just going off to the scene of horrors. Let us be thankful that we belong to a profession which alone in this terrible hour of affliction is able to render consolation to the unfortunate victims of modern warfare. Verily, the trade of the soldier and of the doctor are the most opposed of all trades. *We* endeavour to blow up the expiring embers of an exhausted vitality; *they*, on the contrary, take care to destroy the strongest lives by every stratagem, by every kind of cunning invention. Pray tell me how we can reconcile such opposite acts? Which is the true one? I fondly believe that *our* task is the noble one; and that it is a disgrace to the philosophy of France and Prussia that they, and other nations, should still desire to destroy in a moment so many healthy existences. But, our time, *cher compère*, is not come yet. The counsels of the doctor are not heard as yet by the rulers of nations. How many of your representatives in Britain are doctors? How many here? Spiritualism, superstition, and love of glory yet reign supreme, and we thus have here to bewail in tears the loss of our best and dearest friends. We expect to hear of a fearful carnage this very day, or in a few days. You will know all by telegraph long before you can print this letter.

[FROM OUR SPECIAL CORRESPONDENT.]

LAUSANNE, August 16th.

THE war spreads its indirect ravages as far as Switzerland. The Helvetic Confederation, so proud of her liberty, always depends, to some extent, for supplies on Germany and France, which extend on both sides. The interrupted communications very much increase the value of foreign goods—sugar, coffee, cocoa, wines, corn have all doubly augmented even where we continue to receive them. Add to this, all the Swiss hotels are deserted because everybody has returned to his own country, while the harvests have been totally destroyed by long and extraordinary drought, and you will have an idea of the dull position in which our inhabitants are placed. Yes, the war is a real abomination; and, if we did not know that the interest of our country requires the success of the French arms, we should not know on which side to turn our resentment. There are such black clouds on the horizon that we dare not say our thoughts! Our fathers have experienced the same calamities, and we could not hope to be more favoured than they.

Picture to yourself butter at five francs a pound, and other things in proportion; and in some parts water being sold at one or two sous a litre, and you have some idea of the horrors of war to innocent neutrals on the borders of contending countries.

FROM OUR SPECIAL CORRESPONDENT.

AMPHION, NEAR EVIAN, SAVOY,
August 12th.

YOU should make your readers acquainted with this charming refuge, now that so many continental resorts are inaccessible. Besides the alkaline and chalybeate waters, the lovely scenery, the healthy temperate climate and other things make this place very attractive. At the end of July, when the heat was most oppressive in all parts of Europe, the maximum here was 73 or 74 degrees, while I hear that the mean in Florence was 100, in Paris and London 95. There is a fine establishment here, of which Dr. De Pascale, so well known by English visitors to Nice, where he spends the winter months, is the medical officer. I am told he visited the springs eight years ago, so he must know their value.

We are situated here nearly opposite to Lausanne, where, as most travellers know, is the finest Swiss hotel. We are in a fine shady park which contains three good hotels, where, besides the powerful mineral waters, you may find every comfort for a summer home.

Invalids come from long distances. English and American travellers abound here, and all your friends who are driven from the German watering places would find this quite as good. As to the mineral waters, I will send you further particulars in a future letter.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 24, 1870.

THE NEW M.P. FOR DUBLIN CITY.

Sir Dominic John Corrigan, of Cappagh and Inniscorrig, county of Dublin, who was elected M.P. for the city of Dublin in the Liberal interest, in the place of Sir Arthur E. Guinness, unseated on petition, and whose seat has remained vacant for eighteen months, is a physician of great eminence in Dublin. He is a son of the late Mr. John Corrigan, an eminent merchant of Dublin; his mother was a Miss Celia O'Connor. He was born on the 1st of December, 1802, and graduated M.D. at the University of Edinburgh in 1825 and at Dublin in 1849. He became a member of the College of Surgeons (England) as far back as 1843. He has been President of the Pathological Society in Ireland, and Physician to the House of Industry Hospitals at Dublin, from which he retired in 1866. He was appointed one of the members of the Senate of the Queen's University in Ireland, at its first establishment in 1847, and was five times in succession elected President of the Royal College of Physicians in Ireland—an honour never before him bestowed on any of its Fellows. He holds the post of one of Her Majesty's Physicians in Ordinary in Ireland, and is the author of numerous contributions to leading medical journals. He was created a Baronet in February, 1866, in recognition not only of his very high and distinguished professional position, but also of his great and gratuitous services through many years to the cause of health and education in his native country. Sir Dominic, who had long been known in Dublin as one of the most zealous, but at the same time truly Liberal, members of the Roman Catholic body, married in 1829 Joanna Mary, daughter of the late Mr. William Woodlock, of Dublin, by whom he has had two daughters and three sons. His eldest son, who was captain in the 3rd Regiment of Dragoon Guards, having died in 1866, his heir is his grandson, John Joseph, who was born in 1859.

Sir Dominic Corrigan has won his seat in Parliament not without repeated battles and his full share of election *desagremens*, and it is in the highest degree honourable to him that a constituency so extensive, and so evenly divided in political feeling, should have chosen him. The representation of Dublin is just in that condition of even balance that the personal merits of a candidate have considerable influence on his success, and may be sufficient to turn the scale by getting him a few votes or by rendering personal friends, and political foes, indisposed to oppose his election. Sir Dominic Corrigan has suffered more or less from the undeserved opprobrium of being a "mere doctor;" indeed that disqualification was repeatedly urged against him by one of the Dublin papers; yet he has managed to step out from his professional character and make himself a public man principally by the force of his personal qualifications.

It affords us great satisfaction that one more member of our Profession—one more representative who can teach the House of Commons a little much-lacked wisdom on matters medical—has been sent forward to the deliberations of Parliament. It is only a few years since we uttered a lament over the entire absence of medical men in the House of Commons—Sir John Gray and Dr. Brady being then the only members having any connection with medicine. From year to year the number of medical candidates has increased, and of the many who have essayed the *escalade* of the fortress, several have had the luck, or the merit, to find themselves inside.

Believing, therefore, that the neglect which medicine and its affairs have met with at the hands of Parliament has been in the greatest measure owing to the infinitely small proportion of its constituent members which medicine supplies, we rejoice that a medical man, and one so thoroughly experienced on past medical legislation, should be added to the strength of the contingent of our Profession; and we plume ourselves on the occurrence, not only in anticipation of actual work which may be done in the interest of our Profession, but as an evidence of an awakening amongst medical men. Within a few years ago it was part of the creed of our Profession that doctors should be doctors *et preterea nil*, and that curing disease, or at least success in conciliating patients, was incompatible with the possession of a political judgment. Doctors made a boast of knowing and caring nothing about those public questions which interest all the world else; and, so far from daring to ascend the hustings or to avow decided politico-religious views, they occupied in political matters no more admirable *rôle* than that of Serjeant Eithersides.

A very few general elections have changed all this, and the Profession, without embarking in political agitations or professional discussions, has shown that its members have their own opinion, and will no longer allow subserviency to the ideas of their clients to forbid the expression of their views. While Sir Dominic Corrigan is thoroughly identified with medicine, and may be expected to throw his whole influence into the progress of medical matters in the House of Commons, yet he owes nothing of his new position to the Profession. He neither courted nor obtained the support of his Profession, and he takes his seat not at all identified, as Dr. Playfair is, with medical interests, but as the representative of the Radicalism of Dublin. His first appeal to the constituency gave great offence to his brethren, by omitting the least reference to medical matters, and he was feign to make a tardy reparation by the issue of a second address special to his own Profession.

Perhaps this omission materially increased the opposition which his candidature met with from the medical men; at all events, a very large proportion of the Profession thought fit to step forth from public neutrality and disavow any participation in his political views; and this protest has perpetuated its influence at the recent election in the entire ignoring of the Profession by Sir Dominic Corrigan, and the voting against him of very many of his medical brethren.

Considering Sir Dominic Corrigan's election with reference to the Medical Reforms now on the anvil, the advantage to the Profession of his voice in the matter is a question on which very different views will be entertained. The new medical M.P. will bring to the subject long experience, anxious thought, great administrative and discriminative power, and considerable eloquence; and if he enters Parliament without bias or prejudice, he will be acknowledged to possess qualifications of the greatest value in the settlement of the matters at issue. But he is a member of the Medical Council, thoroughly ingrained with University and Corporation sentiments, and, as readers of the proceedings of the Medical Council know, entertaining very strong and peculiar views. He has shown himself, moreover, persistent and unyielding in his opinions, and the Profession must, we fear, expect, therefore, to see Medical Reforms moulded to a certain extent in accordance with his hobbies.

Sir Dominic Corrigan's will be the loudest medical voice in the Legislature. Whether his powers will be exercised for the permanent benefit of the Profession in its relation to the public, remains for the experience of next session to show.

THE DISAGREEMENT AT NEWCASTLE.

We regret to see that a contemporary takes exception to the action of Drs. Stokes, Paget, and Rumsey at Newcastle, and considers their conduct as interfering with the freedom of the Association. We look upon this as a great mistake. These eminent Members of the General Medical Council could scarcely do less than proclaim their dissent from the opinions of the leaders of the Association.

It is well known that these leaders do not represent the members of the Association, and we are surprised that our contemporary should speak as if they did. Every one who opened his ears at Newcastle might hear the word "clique" spoken in a most contemptuous manner on every hand, might almost, without asking, satisfy himself that feelings of indignation are gradually accumulating that will either sweep away the existing organization, or compel it to give way to something like a really representative system. To say that "the action of the Direct Representation Committee has the entire approval of the members of the Association" is to display absolute ignorance of the sentiments of the Profession. It would be far more correct to assert that the general apathy of the many, and their absorption in other pursuits, has enabled a few men to carry out their wishes with the apparent concurrence of the Association.

Very few practitioners look upon this as a vital question, still fewer really understand it, therefore the committee has been suffered to do much as it pleased. But it must not be forgotten that the only time the Association has ever been appealed to, its judgment was in direct opposition to that committee. That judgment could not be gainsaid, but the committee obtained from its own clique permission to ignore it, and thus, in a manner that we believe has never been paralleled, it has been allowed to override the deliberate expression of the members of the Association. Such conduct would have been well met by a vote of want of confidence, but, as we have often said, there are the apathetic majority who would rather let things "slide," and therefore the committee still amuses itself.

As a political body, the Association does not exist. It in no way represents the Profession, and its own executive is not representative of its members. Yet that executive pretends to speak in the name of the Association. The thing is altogether ludicrous, and was quite condemned at the meeting of Members of the House of Commons, when it was, as we have already said, shown that in pretending to represent the Profession it was putting forward a claim to which it had no title whatever. This is a public question, and we, therefore, speak freely. We might go into other matters, as to the Council's report, and the many objections we heard urged against it; but it is scarcely worth while. Like almost everything else at Newcastle, the whole was accepted as a part of the holiday. Men go and look, and leave from year to year. They grumble about the names that year after year keep their places among the officials; but they will not take the trouble, or will not disturb the hollow harmony that the holiday time requires by insisting on some change for the better.

It is thus that a numerous society, pretending to advance the art of medicine, has degenerated into a mere co-operative printing association. The journal is all that results from the organization—a medium for printing the papers read at meetings, but which does not accomplish that end, as the branches find their proceedings growing "small by degrees and beautifully less," to make room for the productions of a few men, mere gossiping paragraphs, sensational reports, or stale portraits. There is no longer a deference to Science; but the worship of success in a commercial sense. Would it not be as well to change the name of this Society to that of "Medical *Journal* Association?"

As the opinion of Drs. Stokes, Paget, and Rumsey cannot but be respected, we rejoice that they said what they did, and only wish they had gone a little further; then, perhaps, the spirit of *laissez faire* might no longer control all.

REGULATION OF PROSTITUTION.

A measure has come into operation at St. Louis which is more stringent than might have been expected from the western world. All houses of ill-fame and of assignation within the city boundaries are at once to be reported by the police to the Board of Health. Then it is provided that—

"The said Board of Health shall divide the city into districts, and for each district shall appoint a physician, whose duty it shall be to visit, at least once a week, each of the houses of ill-fame, and rooms used or occupied by prostitutes, in his district; a list of these, together with a list of all prostitutes and their places of living, shall be furnished to him by the Board of Health, for his sole use and inspection. Such physician shall then carefully inquire into the sanitary condition of the prostitutes, and, if necessary, subject them to an examination; shall make all necessary orders and give all proper directions for their sanitary management: he may order the removal of any of the inmates to the hospital hereinafter designated; and in any case where there is danger of infection he shall order such removal, or such action as shall

remove such danger. He shall furnish weekly a full report of his action, and of the condition of all such houses and their inmates, to said Board of Health. The keeper or person in charge of every such house shall pay to such physician the sum of one dollar for each inmate, weekly, which money shall be delivered to the clerk of the Board of Health, subject to the order of the said board. Any person violating or disobeying the order of such physician, or obstructing, hindering, or preventing him from discharging his duties as herein prescribed, shall be deemed guilty of misdemeanour, and be fined not less than twenty dollars, provided that any person may, within three days, in writing, after its issue, appeal from any order of said physician to the Board of Health, which shall thereupon grant a hearing to such person, and its action thereupon shall be final in the premises, and disobedience of any order therein made be punishable as in this section provided."

Further, houses of correction and lock hospitals are to be provided, contagious sexual diseases are to be excluded from other hospitals, and the police commissioners are empowered to suppress any brothel at the request of the Board of Health.

It will be seen that at St. Louis it is not proposed to adopt any half measures. It remains to be seen whether so stringent an enactment will prove practicable. If so, perhaps the St. Louis Board of Health will request the police commissioners to suppress *all* the houses of ill-fame, and so put an end to the evil of clandestine prostitution. That, we suppose, will not be easy to suppress. This enactment makes the medical man the collector of the money, a point to which most would take exception, and yet the sixth clause repeats this which, we do not like. Thus :—

"Each physician appointed by the Board of Health, as prescribed by section three of this ordinance, shall, in addition to the examining fee, collect such sum from each keeper of any house of ill-fame, and from each prostitute, as may be fixed or prescribed by the Board of Health jointly with the Board of Police Commissioners. Such fees shall be known as hospital dues, and shall be paid to the clerk of the Board of Health, who shall hold the same subject to order of said board."

The measure is a bold one, but something like it has been proposed in this country. Dr. H. W. Williams, some time ago, proposed in our columns a scheme by which the expenses could be paid of regulating prostitution and subjecting it to medical supervision. We think, indeed, the scheme of Dr. Williams was a better one than has been adopted in America, and we, therefore, commend it to the St. Louis authority.

Notes on Current Topics.

Medical Officers, Greenwich Hospital.

The School of the Greenwich Hospital is to be remodelled. A superintendent and a medical officer have been appointed. The latter is to diagnose, dispense, operate when necessary, act occasionally as superintendent (in the absence of *that* gentleman), and in every way become the recognised "smart boy" to the establishment. Are "My Lords" really sincere in their arrangements? Have they consulted the Medical Director-General in the matter of their medical appointment, and does that experienced gentleman recommend that *one* medical officer only be selected to discharge the duty of professionally attending to the medical and surgical wants of 800 scholars, independent of the other duties allotted to him?

Health of the City of London Police.

Mr. P. Childs, F.R.C.S., has issued the annual report of the sickness and mortality of the City of London Police.

The strength of the *City* section of the force averages 700 men, of whom about one-fourth are unmarried, and more prone to sickness than their married comrades, yet their mortality has been less.

During the year 340 men were admitted to hospital, six died, and the average duration of illness was 11·45 days.

Rheumatism and catarrh appear to be prevailing disorders, and the men on night duty suffer from bad health much more than those on day duty.

During the year 148 candidates for admission to the force were examined, out of which number 47 were rejected. Compared with other "arms of the service," the City of London police contrasts favourably.

Report on Chelsea Hospital.

The committee appointed to inquire into the establishments of Chelsea and Kilmainham have issued their report. Chelsea Hospital accommodates 538 in-pensioners. No candidate is admitted under fifty years of age, unless suffering from the effects of a disability contracted in the service, or specially fitted for some employment in the hospital. The age of the oldest in-pensioner is ninety-four; there are 169 pensioners over seventy and under eighty, and 58 between eighty and ninety. The average cost of each pensioner is 2s. 3d. a day. The committee laud the general arrangements in the hospital and the infirmary attached to it. Although the men might consider an increase of out-pension as superior to the advantages to be derived from residence within the walls of the building, it would seem that there are several considerations to make the committee hesitate before acceding to this. In the first place, a large number of in-pensioners are either patients in the infirmary or require frequent medical attendance; and it is almost certain that in many of these cases no amount of increased pension would enable them to be cared for outside the hospital better than they are at present. It is also thought probable that if the men were out-pensioners with increased pensions, many of them would find their way to workhouses, or become the prey of lodging-house keepers. The committee are not prepared to recommend the abolition of the system. They think that some reduction might be made in the administrative staff without impairing its efficiency; and that its monastic character might be overcome by making some arrangement for the reception of a limited number of married pensioners, with their wives, within the institution. The committee make other recommendations; and it is gratifying to find that the condition of Chelsea Hospital contrasts favourably with that of other establishments. The report of the committee so far deals exclusively with Chelsea Hospital.

War.

All the assistants of the Berlin Chemical Laboratory have gone to the war as apothecaries. Great numbers of students have also gone forward. The University classes have been closed. Some of the higher schools have actually sent their elder pupils into the field.

"All at Ninepence-Ha'p'ny."

The above *odd* sum is the charge lately made by a London "practitioner" (registered) to a patient of considerable means for *advice, four-ounce mixture,* and *one powder.* O tempora! O mores! What next?

Since we penned the foregoing, a circular—the copy of which we submit—has been placed in our hands:

——————— Street.

SELF-SUPPORTING DISPENSARY.

This Dispeusary was opened by

Mr. ———, M.R.C.S. and L.S.A.

To afford Medical and Surgical relief to the necessitous and deserving.

Attendance every morning from nine to twelve, and every evening from six until nine o'clock.

Each Patient must bring a clean bottle, also a gallipot and bandages if required.

To meet the working expenses, the charge for each Patient will be Fourpence in the morning and Sixpence in the evening.

The charge includes advice, medicine, and *every other requisite.*

A visit to any Dispensary Patient within a radius of two miles will be One Shilling.

Of *such* are the ills to which the flesh is heir.

Rennett Extracts.

The allegation has been made—with what truth we know not—and generally believed, that the essence of rennett usually sold contains no pepsine whatever, knows nothing of the calf's stomach, and is little else than vinegar and water. There is obviously the greatest temptation to sophistication, inasmuch as the genuine article would cost much time and trouble, and the adulterated one—which, as far as the consumer could judge, would serve its purpose as well or better—would involve none at all. The separation of the curd is, however, the smallest part of the duty of essence of rennett, and for medical purposes any composition not containing the peptic principle would be worse than useless.

Messrs. M'Master and Co., of Dublin, have commenced the manufacture of a new essence introduced by Mr. Warren. We have made an examination of it, and we find that it is but faintly acid, and contains only a very small quantity of chloride, which, we take for granted, is common salt. It coagulates milk very readily, and appears to be in every respect what it professes to be. Dr. Cameron, the analyst of the City of Dublin, has also examined it, and certifies in the strongest terms to its purity.

Contagious Diseases Act at Portsmouth.

The Director-General of the Naval Medical Department, Dr. Armstrong, during his recent official visit to Portsmouth, was engaged in investigating the working of the Contagious Diseases Act at that port, and it is believed that one result of his inquiries will be that the medical duties will be entrusted to a surgeon belonging to the naval service, instead of to a private practitioner, as is at present the case.

Anæsthetics, their Relative Safety.

From a careful examination of the statistics of 209,893 cases, Professor E. Andrews gives in the *Chicago Medical Examiner* the following estimate of the relative danger from different anæsthetics:—Sul. ether, 1 death to 23,204 administrations; chloroform, 1 death to 2,723 administrations; mixed chloroform and ether, 1 death to 5,588 administrations; bichloride of methylene, 1 death to 7,000 administrations; nitrous oxide, no death in 75,000 administrations.

Somnambulism.

We have observed of late several accidents which have befallen somnambulists announced in the daily papers, occurrences which we consider should never have happened had the disease been understood in its details by the people around the unhappy sufferers. In order that the malady may be more properly understood, we briefly allude to the subject in the form of annotation, guarding ourselves against any personal allusions to particular cases, one of which that has just come to our ears being singularly painful to the respected family of the unfortunate victim; unfortunate in the twofold sense of suffering from somnambulism, and in being ignorantly neglected. We do not purpose referring to the *symptomatic* or morbid somnambulism, which is met with in the course of certain nervous diseases, and which either accompany the malady to its termination, or yield with it to a judicious treatment; nor to the *artificial* somnambulism aroused into action by the mesmerist or animal magnetizer; but our duty is connected with *essential* somnambulism, which is the particular disposition of the nervous system of persons in other respects perfectly healthy, intimately connected with the train of phenomena developed in the act of dreaming, insensible to external agents, but obedient to a consciousness centred in the brain and spinal cord, which can no more be cured by the physician than the act of dreaming can be dispelled by those who suffer so severely from nightmare. However healthy the *essential* somnambulist may be in his waking moments, it is the doctor's function to advise against a danger which is always impending, and to which every sensible minded patient should unmurmuringly submit. The treatment must be preventative; the sufferer from this grave infirmity should be compelled to occupy a secure room, spare of furniture, with barricaded windows; the door should be secured from without by the occupant of a neighbouring chamber, and the patient made alive to his ailment. There is no object of good resulting in concealment. All the accidents which occur are due to thoughtlessness and carelessness, and a studied eagerness to conceal from the patient the fact he is a sleep-walker, which is a mistaken kindness, for this want of candour and precaution have plunged many a family into mourning, and sent many a victim to an early grave. The treatment during a fit, when sensibility is extinguished, should never be to awaken the somnambulist at once; the shock has been known to produce lamentable consequences; but we should try to enter into the course of ideas followed by the patient, save him from danger tenderly and studiously, and endeavour to guide and direct him gradually into wakefulness and reasonableness. Whilst the great object should be prevention, we must guard also against those exciting causes most likely calculated to produce heavy sleep, nightmare, and disagreeable dreams, as heavy suppers, wines, &c.; and we must also counteract all irritability of habit and system, and quickly remedy every morbid condition of stomach that may present itself; but even when least ex-

pected, and the patient's health is best, sleep-walking takes place, and, if no precautions are taken, we have very sad and deplorable accidents occurring.

Water-Cress.

Several severe cases of diarrhœa, traceable to eating water-cress, came under our notice last week, and intractable they proved until the cress was dislodged from the intestinal tract. Allowing that water-cress, when young and seasonable, is a harmless luxury, we are surprised inspectors of markets allow at this time of the year such an importation. We suppose water-cress always sounds as it should eat, and poor people never trouble about thinking until infected by disease, that those plants which live entirely on water, and which require a preponderating quantity as the medium of their existence, become injured during protracted drought, acrid owing to the stagnant, muddy water which barely gives them life—accordingly, most unwholesome and deleterious. We think inspectors of markets, for the sake of the health of the people, should possess the power to prevent unseasonable vegetables and fish being sold, in the same way as they have the authority vested in them of seizing decomposed food.

The Holbeach Board of Guardians.

We observe the Holbeach Board of Guardians are sorely perplexed by one of the Medical Officers, who returns the diseases of his sick paupers in a nomenclature too difficult for their comprehension. They want a standard and classified nomenclature specially for themselves, since such diseases as icterus, ascites, enlarged bursæ, &c., puzzle them no little. If we err not, it was a member of this worthy community who, hearing a few weeks ago that one of the sick was having chlorodyne, became angry in his horror, whilst he failed to catch the correct word, at such wilful extravagance as giving *Collared kyne* to a pauper, which he insisted upon was nothing more or less than a luxury. With all due respect, then, to our friends in the fenny district, we don't believe it possible to frame a nomenclature that would either please them, or that they could comprehend. "A little knowledge is a dangerous thing," so they had better leave matters to their Medical Officers, and remain in the *Nephalococcygia* of Aurora Leigh, which is a territory in the clouds assigned to cuckoos for the building of their nests, and where the inmates of the Holbeach Workhouse possess their estates.

Death from Fright.

We noticed a few weeks ago in the daily papers the case of a child recorded, who was frightened at night by a servant, which, ultimately, terminated fatally. This foolish frolic, out of which no good can arise, should be sternly discountenanced; but the instance before us, considering the influence sudden fright exercises upon some people, makes us ponder and ask ourselves the question how many of those sudden deaths may not be attributed to fright, so generally accounted for by a diseased heart. We knew a gentleman a few years ago whom we heard repeatedly assert that, if he ever saw any unaccountable phenomenon, he believed it would kill him directly. Strange to say, this man went out fowling one evening, and, as he did not return, his relations went to seek him, when they discovered him on his knees at the back of a ditch with the gun resting on his right shoulder and on the edge of the ditch as in the act of taking aim at some object, but quite dead. He never suffered from organic disease previously.

The Climate of Ireland.

A writer in *Nature*, under the initials W. D. C., refers to the climate of Ireland, and points out, on scientific grounds, the peculiar reference of the question to the agricultural prosperity of that country. He says—"It has been stated in the House of Commons, as a proof of the retrograde condition of Ireland, that its production of cereals has of late years diminished, while its pasture lands have increased. To this it ought to have been answered that the decreased cultivation of cereals, and of wheat in particular, was a proof of improved knowledge. It is commonly stated that Ireland has a very wet climate. It has, undoubtedly, a humid atmosphere, owing, perhaps, in some measure, to a large extent of undrained surface. But the total quantity of rain that falls in Ireland, little, if at all, exceeds the rainfall of England. In its distribution through the year, however, it differs much from the latter The vicinity of the Atlantic gives Ireland, in the highest degree, an oceanic and, to some extent, an equatorial climate. Winter in the Green Isle is extremely mild. The southern and western coasts, though seldom free from wind and drizzling rain, never experience severe cold. Vegetation remains in mid-winter brilliantly green and undepressed. As spring advances, everything seems to flourish; crops of all kinds promise abundance, and already (in May) harvest seems to be close at hand. But now the scene changes—there is little or no dry summer. When the sun is highest in the meridian, there is a constantly clouded sky and no sunshine. Rain begins to fall in June. The rainfall in July is the heaviest in the year. In August the rain begins to abate; but clear skies and bright sunshine cannot be reckoned on till September, when the shortened days and the sun's declination have much reduced the solar heat. From this it will be seen that the character of the Irish climate is, that under it everything grows well, but that the process of ripening is painfully slow and uncertain. Now, to cultivators of cereals the success of this process is of the utmost importance. The corn harvest in Ireland falls late in the year, September and October, when the days are short and nocturnal frosts not unfrequent. The plains of Southern Russia, or of the Red River in Canada, with a comparatively rigorous climate, far excel Ireland as wheat-producing countries, because their short summer is one of uninterrupted fierce sunshine. Under these circumstances it is evident that the Irish farmer ought to cultivate cereals no further than is requisite for the economy of his farm, and to look to other productions for his profit. Fortunately, there is a husbandry for the pursuit of which he enjoys peculiar advantages. In green crops no country can compete with Ireland, where, nevertheless, they are still little known or esteemed by the multitude."

The Pathology and Rationale of Cholera.

The results of the Army Sanitary Commission on Dr. Murray's Report on the Treatment of Cholera have been published as an appendix to the *Gazette of India*. Drs. Hope Grant, Galton, Sutherland, Massy, Murray, Baker, Martin, and Rawlinson have decided that the cause of

cholera is still unknown, and that it may result from anything; and that the best thing to be done, when it appears in one place, is to remove to another. All are agreed that from the moment the first symptoms appear, even in their mildest and most simple form, treatment is of vital importance.

On, St. Pancras!

A SHORT time since we cautioned the Guardians of St. Pancras Parish against entertaining the very absurd suggestion made to them of reducing the number of district medical officers, and stated that the requirements of the poor demanded rather its increase than its diminution. In our views of the case we felt certain the Poor-law Board would heartily join, and that the intelligence and common sense of the Guardians themselves would likewise cause them, in a little time, to be with us. It now affords us very great pleasure indeed to be able to state that an *increase* of district medical officers has been decided on, and with the sanction of the Poor-law Board—*de bonne grâce*.

To complete the scheme, and to make it truly effective, the Poor-law Guardians of St. Pancras Parish should now boldly decide on giving their district medical officers remuneration at the rate of £350 per annum, and thereby enable them to devote their time *exclusively* to parish duties.

We shall feel extremely glad to hear that the Guardians of St. Pancras Parish take the initiative in this matter; for, to see the district medical officers of the Metropolis attend to parish duties solely, is just a question of time; and, should the Guardians act on our suggestion, they will simply be the precursors to a beneficent change that must come!

Dr. Wilson, R.N.

BY the decease of this honourable physician to the Queen there is a vacancy to that appointment, and to a good-service pension.

The "Lancet's" Inconsistency.

OUR cotemporary's, the *Lancet's*, inconsistency on the insane, and upon the subject of Lunatic Asylums generally, is only to be equalled by the editor's series of editorial articles on the treatment of sexual disorders; or, to be more accurate, spermatic diseases. Lately we drew attention to the dangerous nature of the remedies advocated, and this week we are glad to notice that our observations are not lost upon even our cotemporary. After recommending matrimony as a physiological remedy for incurable cases of masturbation one week, it is surprising to find the next week, after our severe strictures on this point, that not only is the formerly preached doctrine revoked, but it is held that matrimony, entered into by a man of questionable power, is an immoral and unmanly act. The virtue of the deceived wife is held up to cloak former remarks. Sexual diseases in the woman are also accounted for by these imprudent marriages. We ask, in the name of common sense—allowing that the *Lancet* has taken advantage of our articles, and made reparation this week—why preach on the 23rd of July last—"The last cases, those in which there is generally libidinous direction of the mind, are the most difficult to treat, since they usually imply the existence of some mental vice or infirmity—often a nature that is distinctly, even if remotely, akin to insanity. Words of counsel or warning are thrown off by such patients as water by a duck's back. *For them the physiological remedy of regular intercourse is probably the only one that would be available;*" and this week advocate the very opposite? This it was aroused our anger, and made us so severe upon our cotemporary; that he has rectified his error we freely acknowledge, but at the cost of wonted inconsistency on his part.

"The Haunted Baronet."

THERE is being published in the columns of *Belgravia* a serial tale, from the pen of a well-known and clever novelist, Mr. Le Fanu, under the title of "The Haunted Baronet." We have nothing to say against the general plot of the story, but we object to the manner Mr. Le Fanu introduces one of his characters, Doctor Torvey, and still more do we regret the unreal manner of dealing with an imaginary Medical practitioner. In describing a character there is nothing like keeping to reality, and, accordingly, to truth. There is not a Medical man of the present day in ten thousand would approach the bedside of a patient thus:—"Here you see, poor fellow, here's cadaveric stiffness; it's very melancholy, but it's all over, he's gone; there's no good trying any more. Come here, Mrs. Jeliper. Did you ever see anyone dead? Look at his eyes, look at his mouth. You ought to have known that with half an eye, and you know trying anything more is all my eye." This over, a man, to all intents and purposes, dead from drowning. All pronounce him deceased. The doctor regales himself with some wine, and remarks—"You have got him very straight, straighter than I thought you could; but the large joints were not so stiff. A very little longer, and you would hardly have got him into his coffin. He'll want a very long one, poor fellow. Short cake is life, man"; and a lot more rubbish of this sort carries us half through the night, when the corpse wakens, gets out of bed, and frightens almost to death the watches at his wake! We don't know where Mr. Le Fanu got his Medical character; it is a poor make-up; spoils the story by an impossible occurrence; and shows the reader Mr. Le Fanu is absolutely ignorant of the way a Medical gentleman does his duty. If Mr. Le Fanu knew more of the country practitioner and his work, he would not have the heart or excuse to slander him—even at the expense of ruining his tale.

It is not too late for Mr. Le Fanu to modify the character he has selected; but, in making a change, we recommend him to adhere to the Medical man of the present day, to inquire into his method of practising, and make himself acquainted with his habits. No doctor that we can know ever acted as this Doctor Torvey, the offspring of Mr. Le Fanu's fertile but, in this instance, unjust imagination, which is nothing more or less than a cruel slander upon an overworked, underpaid class of professional men, who are not valued as they deserve, although their lives are ever at the disposal of their patients, and all risk in contracting disease set aside in the demand of duty. We hope the continuation of the tale will show that our hint, for Mr. Le Fanu's own sake, and that of *Belgravia*, since his remarks cannot injure our brethren, has been acted upon.

THIRTY-THREE ladies have been dubbed Bachelors of Arts at Vasser College, U.S.

Diarrhœa is decreasing in London, but not in the other large towns.

The baby-farming case has been postponed to next session.

A death from chloroform at the Liverpool Infirmary is reported.

The foot-and-mouth disease is spreading in several parts of England.

The Twelfth Report of the Medical Officer of Health, to be issued immediately, will contain some account of the Medical Reform efforts of the Privy Council.

In the Medical Department of Harvard University, Washington, are twenty-three coloured and seven white students.

Mr. Solly has declined to deliver the next Hunterian Oration at the Royal College of Surgeons. It will probably be delivered by the President.

318 members of the Profession attended the late meeting of the British Medical Association in Newcastle, of whom Ireland contributed only eight.

Mr. H. Pownall, late Chairman of the Middlesex Sessions, submitted recently to the Committee of the Society for Aid to the Sick and Wounded a sample of very finely picked oakum, which has been used in some of the London hospitals, as a substitute for lint in dressing wounds.

In the St. Pancras parish lately, a young married woman, named Cox, committed suicide by means of her husband's pen-knife. The gash extended from ear to ear, dividing the superficial vessels, the attachments of the os hyoides and glossal muscles, and exposing the posterior wall of the fauces. Neither sterno-mastoid muscles nor carotid arteries were injured. Hereditary tendency to insanity is attributed as the cause of this sanguinary deed.

The Thirtieth Report of the Petition Committee of the House of Commons shows that Dr. Brady's Medical Superannuation Bill did not receive from the Poor-law Medical Officers of England that active support which the efforts of its introducer, and the objects of the measure, deserved. In favour of the Bill 276 petitions were presented, of which 9 emanated from Corporations or Associations, and were officially signed by the responsible officers. These 276 petitions had only 722 signatures, or not 3 for each. Against the Bill 6 petitions, all from Boards of Guardians, were presented.

The *United Service Gazette* hears, upon excellent authority, that steps are being taken to remodel what remains of the old Army Hospital Corps. At present the subordinate staff of a military hospital is furnished partly by the Hospital Corps, numbering about 300 men, and partly by the regimental establishments, consisting of an hospital sergeant and two or three orderlies, according to whether the regiment is cavalry or infantry. It is contemplated to bring about a fusion of these two elements, so as to make one large corps that shall be movable at will from one regiment to another, and which, in the event of an outbreak of war, would form the nucleus for a large body of trained hospital attendants.

The Thirtieth Report of the Committee of the House of Commons on Petitions tells an eloquent tale of the feeling of the Profession towards the late departed, but not lamented, Medical Bill. Three Petitions were presented absolutely antagonistic to it, containing 343 signatures; 351 Petitions praying for alterations in its provisions, to which 9,025 signatures were attached, several of which represented, officially, Corporations or Associations of the Profession. Not a single voice was raised in its favour; and even the Homœopaths thought so little of it as a protection against quackery that they paid it the bad compliment of asking to be included in its provisions. One petition, with 140 signatures, was presented in furtherance of this object.

It appears unnecessary to go beyond these facts in condemnation of the Bill. Even from Universities, in whose interests it forsook all its principles, it received no favour; and it is obvious that, while it might have been tolerated by Licensing Bodies and the Medical Council, for the same reason that the Irish Land Bill was tolerated by the Irish landlords, because it was not so bad as was feared, it was received by the Profession with unalloyed dislike and distrust.

We wonder whether the Members of the House ever hear, even in the aggregate, of the petitions which are directed to lie on, or rather under, the table.

Experiments on the Absorbent Power of the Bladder.

Physicians and physiologists are by no means agreed on th power of absorption possessed by the mucous membrane of the urinary bladder. While some assert that the excrementitious substances of the urine would constantly be carried back to the circulation if this absorption took place, others deny this fact. M. Beclard asserts that the fluids contained in the excretory reservoirs (the urinary and biliary bladders) are in the process of absorption. We should remember that the epithelial lining membrane of these viscera consists of stratified layers of pavement epithelium, which is less easily traversed by fluids than the simple membrane of the serous cavities. Nevertheless, a slight absorption takes place in these organs. The morning urine, which has remained a part of the night in the bladder, is of a darker colour than the urine of the day, and also than that which has been passed after taking fluids.

Recent experiments of Bert and Joylet confirm those of M. Ségalas, and demonstrate the fact that the bladder in health rapidly absorbs certain substances introduced into it. A solution of strychnia, one part in one hundred, was carefully injected into the bladders of several rabbits, causing their death at the end of four minutes, although a few milligrammes only of the salt had been introduced, and a part of this had been removed by injections of water on the first appearance of symptoms of poisoning. Autopsy showed that the mucous membrane of the viscus remained healthy. Injections of a solution of atropia did not kill the animal or sensibly diminish the pupil.

The possibility of causing certain substances to be absorbed by the healthy bladder offers a therapeutic resource of considerable importance; in cholera, for instance, where medicines cannot be absorbed by the stomach and intestines, advantage can be taken of the circumstance that the bladder is habitually empty, for the injection of certain solutions which experience has shown to be absorbed. During an epidemic of cholera, M. Brown Séquard injected into the bladder of several patients laudanum and alkaline carbonates, and he was convinced that these substances were absorbed in considerable amounts. Experiments of a similar character have been tried in Germany and Italy.—*L'Union Méd.*

THE SEWAGE QUESTION.

SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. I.

OUR readers will remember that last month we published *in extenso* the remarkable paper on "The Prospects of the Sewage Question," read by Dr. Letheby before the Metropolitan Association of Medical Officers of Health, and that we followed this up with a full report of the discussion that took place.

This important contribution to our knowledge of the most urgent sanitary question of the day has brought out further discussion in various quarters. Since then, too, another blue book has appeared by the Royal Commissioners on the Pollution of Rivers, and the Health Department of the Social Science Association has arranged that the first special subject for discussion at the Congress next month shall be the best method of disposing of sewage and excreta.

For the above and other reasons this has appeared to us a peculiarly favourable time to take up in earnest the great questions relating to sewage—questions which, whether regarded from a hygienic, agricultural, or commercial point of view, cannot be too thoroughly sifted, and which in all their phases can only be grasped by medical men.

We therefore determined to employ the machinery at our command for the preparation of one of these special reports for which the MEDICAL PRESS has long been well known. The duty of our reporters is to collect and lay before our readers in the simplest form the most important facts, so as to furnish a complete digest of the results that have been attained, from which we may afterwards draw such inferences as the inquiry may justify.

As the chemical investigations must of necessity be of the utmost importance in such an inquiry, and as Dr. Letheby has spent much time in these special investigations, and his authority upon every point likely to turn up is second to that of no living man, as soon as we had determined to issue a special report, our chief London editor applied to his learned colleague for permission to peruse some of his notes on the places he had visited—a permission that was more than accorded, for the Doctor at once freely placed at his disposal the whole of the notes he had taken on the actual condition of the sewage farms of this country, and of all the works where chemical processes are employed for the purpose of defæcating sewage. This generous offer was at once accepted, and these notes will accordingly furnish the basis of this report; for we shall publish a condensed summary of the whole, so as to provide our readers with a reliable account of what has been done at every place where any attempt has been made to cope with the sewage question.

Our staff having also been promised the assistance of other competent observers who have visited the various places, we trust that the facts we have to submit, and the conclusions we may have to deduce, will take rank as of permanent value, and assist in the solution of a great national problem. The plan of our report is simple: we shall commence with an account of the several sewage farms, continuing them from week to week, and afterwards proceed to describe the various precipitating processes. In our next we shall report on the

ALDERSHOT SEWAGE FARM.

SCOTLAND.

WE regret to record the death of Dr. John Adamson, who for many years occupied a prominent position as the leading medical practitioner in the City of St. Andrew's. The respect in which he was held is evinced by the universal expressions of regret which his death has called forth.

Summary of Science.

(Specially edited for the MEDICAL PRESS AND CIRCULAR.)

BY C. TICHBORNE, F.C.S., M.R.I.A.

Mem. Council Royal Geological Society of Ireland, Chemist to the Apothecaries Hall of Ireland, &c., &c.

ON THE DIFFERENCE BETWEEN A HAND AND A FOOT.

Dr. HAUGHTON, in a fourth communication upon animal mechanics, considers this subject in connection with the flexor tendons. "The fore feet of vertebrate animals," says the author, "are often used merely as organs of locomotion like the hind feet, and in the higher mammals they are more or less cephalized or appropriated to the use of the brain. The proper use of the hand is to grasp, that of the foot to propel by the intervention of the ground." In a hand proper the strength of each portion of a tendon is proportioned to the force it is required to transmit, and we should, therefore, expect the strength of the tendon above the wrist to be greater than the united strength of the finger-tendons. Conversely, in a foot, we should expect the united strengths of the flexor tendons of the toes to exceed the strength of the flexor tendons above the heel. The author gives the result of his investigations in connection with some thirty-six animals. All the animals realized the typical idea of a true foot with a variable amount of friction at the ankle-joint, this friction disappearing altogether in the Boomer Kangaroo, whose method of progression realizes absolute mechanical perfection, as no force is consumed by the friction of the flexor tendons at the heel. The only animals whose feet deviate from the typical foot were three—viz., the Alligator, Porcupine, and Phalanger; in these the foot has the mechanical action of a hand, and the flexor tendons above the ankles exceed those below.

Dr. Haughton operates in the following manner: He measures the relative strengths of the deep flexor tendons of the hand above and below the wrist, and the relative strengths of the long flexor tendons of the foot above and below the ankle in the following manner: He weighed certain lengths of the tendons above the wrist and ankle and compared their weights with the weights of equal lengths of the flexor tendons of the fingers or toes, assuming that the weights of equal lengths are proportional to their cross sections, and then again proportional to the strengths of the tendons at the place of sections. The difference between the weights above and below the joint represents the sum of all the frictions experienced by the two tendons between the points of section.

CYCLOPIC ACID.

This is the name applied by Mr. Church to a substance which he has procured from the *Cyclopia Vogelii*. When dis-

solved in soda it gives an intense greenish yellow fluorescence. The fluorescence, however, is not permanent, and disappears in some hours. It is soluble in ether, alcohol, and water, and is purified by crystallization from alcohol. The author gives it the formula—

$$C_7 H_8 O_4$$

and the ammonium salt as having the composition—

$$C_7 H_6 (NH_4)_2 O_4$$

PREPARATION OF SODA FROM SODIUM.

Cosmos gives the following as the method pursued in preparing pure soda which is now largely made in England: A silver vessel is used for making it of a deep semi-spherical form, and having a capacity of about forty litres of water, a few drops of distilled water are introduced and a piece of sodium is added cut in a square of about half a cubic inch. The silver vase is turned round, a stream of cold water flowing at the same time round the exterior of the vessel. By this arrangement an explosion of the liberated hydrogen is avoided, fresh fragments of sodium and water are alternately added, until a considerable quantity has collected; the mass is then evaporated to dryness and fused.

INVESTIGATIONS ON THE NERVOUS SYSTEM.

Dr. Augustus Waller, in the Croonian Lecture for May, 1870, says that it is known that, after a nerve has been disconnected from the central organs, its medullary part undergoes a series of changes. The tubular medulla, or white substance, is disintegrated, and finally converted into a dark granular matter. On this alteration Dr. Waller founds his method of investigation, as it enables the inquirer to distinguish the altered from the sound fibres. The author applied his method to the elucidation of the functions of the ganglions or swellings found on the origin of many nerves. On dividing the roots of the spinal nerves it was found, after a certain lapse of time, that on the posterior root, which is alone possessed of a ganglion, the central segument remaining in connection with the spinal cord became disorganized, and its elements passed into a state of granular degeneration, whereas, in the distal segments remaining in connection with the ganglion the nervous elements retain all their normal structure, evidently showing that continuity with the spinal cord does not prevent it from becoming disorganised, whereas, its connection with the inter-vertebral ganglion suffices to preserve its integrity of structure. In the divided anterior root the phenomenon takes place in an exactly inverse manner from the former. The author arrives at the conclusion that the spinal cord confers on the anterior root that unknown vital power whereby its elements resist granular disorganization, whereas, for the posterior root, on the contrary, the preservative power is no longer an attribute of the spinal cord, but resides in the ganglion. The author pointed out the important bearing these results had on pathology, that henceforth, in diseases of the spinal cord and of the brain, experimenters had to endeavour, in pathological examinations of those parts, to ascertain in each case how far the alterations could be referred to the separation of a part from its tropic centre.

The author then treats of the vagus, which, at its origin, is formed by roots springing from the medulla oblongata, to which is added afterwards a considerable branch from the accessories which joins and mingles with the pure vagus, and with which its fibres become intimately blended. The problem to be solved, therefore, is the precise functions of each or of either (the accessories or pure vagus) before their anastomosis. Professor C. Bernard had succeeded in entirely destroying the power of the accessories by evulsion of its roots, and had arrived at the conclusion that all the fibres of this nerve are distributed to the laryngeal muscles, whose functions are connected with the production of vocal sounds, whilst, other fibres from the pure vagus govern certain nutritive or organic functions connected with respiration. In order to separate the functions of the one from the other it is requisite to destroy all the fibres of the accessories by Dr. Waller's process, and leave the others intact, which has been done most effectually by Dr. Waller's plan, first disconnecting the accessories from the medulla on Bernard's plan, and afterwards allowing the animal to live sufficiently long for fatty degeneration to take place. The vagus then having been galvanized at every part of its length it was found impossible to affect either the action of the heart or the stomach, and the only result is to cause slight movements of the larynx. The author then proceeded to the consideration of the pneumogastric and sympathetic nerves in man in health and in certain affections of the nervous system, and, lastly, referred to the effects of collapse and syncope produced by the irritation of these nerves. In general, the effects are confined to a state of depression more or less strong, which may be moderated by graduating the degree of irritation applied. He believed that this fact may be taken advantage of and applied as a means of inducing astenia or debility for the purpose of facilitating certain operations in surgery, such as the reductions of fractures, or even hernia, in lieu of the administration of other anæsthetics such as chloroform, &c., which present a certain degree of danger not attending the compression of the vagus.

Dr. Waller then cites a case of dislocation of the head of the humerus beneath the clavicle by a fall down stairs. After numerous unavailing attempts to reduce the luxation, chloroform was sent for to facilitate the operation by inducing anæsthesia, but in the meantime an attempt was made, assisted by compression of the vagus. One applied compression, whilst the other two operators performed extension and counter extension. In two or three minutes, just as the carotids ceased to be felt to beat, a sudden click indicated the return of the bone to the cavity.

Correspondence.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The case recorded by Mr. R. L. Johnson, in your last number, recalls to my mind a somewhat similar one which fell under my observation some years ago.

I had been in attendance for some time previously on a poor widow woman in a far advanced stage of phthisis, and was hastily summoned by her one day to see her daughter, whose arm she (the daughter) said had been broken by a blow of a ruler, or some such instrument, inflicted by the poor invalid. This child, about fourteen or fifteen years old, was a very wayward girl, and gave her poor mother a great deal of annoyance, and on the present occasion had provoked her to inflict the blow referred to. On examining her wrist, she directed my attention to a projecting body under the skin, covering the lower end of the radius, which the girl positively said was the end of the broken bone. However, from its mobility and sharpness, I did not believe this to be the fact. Having my pocket-case about me, I had not the opportunity of showing such readiness of resource in devising *impromptu* surgical dynamics as Mr. J. I cut down on the projecting point, and with a forceps laid hold of the object, which proved to be a long darning needle, which the young urchin had forced under the skin and up the arm so as completely to imbed it in the subcutaneous cellular tissue, only to use it as an instrument of torture for her poor mother! A strange phase of juvenile depravity! There was no evidence of any hysterical derangement to warrant any conclusion more favourable to the morals of the girl.

I am, &c.,

E. P. SHARKEY, M.B.

Ballinasloe, August 12, 1870.

The Public Health in New York.—The Fourth Annual Report of the New York Board of Health has been published. The volume contains an astonishing amount of sanitary lore. There are separate reports from every official of the board, upon his own specific branch of administration. We must be content to note the fact that, in addition to the sanitary reports, the volume deals with many other subjects coming within the province of a sanitary board. For instance, reports on the Sources of Unhealthiness in crowded assemblies and places of popular amusement, on the Quality of the Milk-supply of the City, and on Poisonous Cosmetics. The New York Board of Health has control over the water, food, and gas supplies of the city, over the management of tenement houses, and over offensive trades and quarantines. The Home Secretary, Mr. Bruce, has promised to deal with the government of London, and it might be well that he make himself acquainted with the manner in which the requirements of sanitary science should be met.

Gleanings.

The Correlations of Temperature, Pulse, and Respiration in Phthisis.

By Assistant-Surgeon Boileau, M.B., 29th Regiment, Quebec.

(From the *Army Medical Department Report.*)

(Continued.)

Corporal T. P., aged twenty-four, service six years, was admitted into hospital on the 9th of April, 1867. He had had fever of eleven days' duration in January of the same year. Shortly after his discharge from hospital, he got a cough which troubled him every morning and every evening. It was at first "quite dry," but latterly he expectorated, pretty freely, a "yellowish matter." Within the last month he has had hæmoptysis, but it occurred once only. He appears to be rather a healthy young fellow, but he has decidedly lost flesh. Both his parents died of consumption, and one of his sisters at the age of nineteen. His skin is soft and delicate. The thoracic movements are not expansile; temperature, 99·4 deg. pulse, sitting, 92, and standing 100. Percussion gives a shade of dulness over the right infra-clavicular region; and here the systolic sound is very audible—more so than in the corresponding opposite region. There is no rough breathing, but the expiratory murmur is prolonged, and is quite equal in length and intensity to the inspiratory. There is, at the end of every forced inspiration, a moist râle in the right lung.

Within ten days I brought this man before an Invaliding Board, the members of which confirmed my diagnosis of phthisis. Nine days after admission, I find the following remark in my case book:—"The sputa is puriform, dulness marked, and deep inspiration produces sonorous râles."

The first observation gave an elevated temperature, 99·4 deg. but subsequently I took 23, morning and evening, with the result that it varied from 98 deg. to 98·8 deg.

On the 2nd of May (twenty-three days after admission) he left Malta for England, and was eventually discharged the Service from Netley Hospital.

Here we have a case in which, for eleven days certainly, a man's temperature was normal, Now if during that time he had been examined by one who believed that elevation of temperature was the constant accompaniment of phthisis, he would have been pronounced free from the disease, whereas he not only had tuberculosis, but some softening of the morbid deposit.

As a further example of the correlation of temperature, pulse, and respiratiou in phthisis, the following are specimens of a large number of observations made on a woman aged thirty, the wife of a soldier in Malta. Her disease extended over a period of four years. The observations were made at various times within eighteen months of her death.

Temperature, 100·8 deg.; pulse, 116; respiration, 48. Symptoms: great debilty, progressive emaciation, dyspnœa, cough, hæmoptysis, anorexia, nausea, vomiting, sputa puriform and mummular, sonorous sibilant, and muco-crepitating râles.

Temperature, 101·6 deg.; pulse, 120; respiration, 44. Symptoms: ditto.

Temperature, 100·6 deg.; pulse, 108; respiration, 42. Extremely weak, stomach very irritable, no hæmoptysis.

Temperature, 100·6 deg.; pulse, 120; respiration, 48.

Temperature, 100·8 deg.; pulse, 112; respiration, 44. Suffers from severe rigors; has occasional pain between the scapulæ.

Temperature, 100 deg.; pulse, 108; respiration, 48.

Temperature, 99·6 deg.; pulse, 100; respiration, 48. Pulse scarcely to be felt; it is so weak and small. Percussion gives, and has always given, an extraordinary clearness of sound, probably due to diminished amount of blood in lungs (Stokes), and in part to the emaciated condition of thoracic parietes (Dr. Clarke).

Temperature, 100 deg.; pulse, 120; respiration, 44.

Temperature, 100·8 deg.; pulse, 120; respiration, 52 Rigors very severe, followed by burning heat of extremities.

Temperature, 98 deg.; pulse, 90; respiration, 48. Wonderful improvement in all her symptoms, which improvement lasted a few months.

Temperature, 99·6 deg.; pulse, 112; respiration, 44.

Temperature, 100 deg.; pulse, 124; respiration, 40. This last recorded observation was taken about six weeks before death, when she was in very marked hectic, and vomicæ were found in several places in the lungs.

Notwithstanding the acceleration of this woman's pulse and respirations, her temperature never exceeded 102 deg. This, one might attribute to the very chronic nature of her complaint; but during the same month in which she first asked my advice, I had under my treatment No. 3,479, Private T.K, aged thirty two, service 15 years, who died of acute tuberculosis in 23 days, in the regimental hospital of the 29th Regiment; and the man's temperature, taken twice daily, never exceeded 102 deg. In fact, reverting to the case, I find this note made on the 20th April, 1867:—"Until the 12th of the month, or the 10th day of his disease his temperature was always normal in the morning, and his evening temperature never exceeded 101·6. Since the 13th inst. it has generally been over 100 deg., but never rose higher than 101·4 deg."

After death we found both lungs closely studded, in every part, with grey miliary granulations very equally distributed. Anteriorly, both organs were emphysematous, but posteriorly both organs were congested (*post-mortem* 32 hours after death). A few nodules of yellow lardaceous tubercle, from one-fourth to one inch in length and breadth, were found isolated in various parts of the upper lobes. Both pleural cavities were completely obliterated by adhesions which had not the character of recent formation.

But in general I have observed that—excepting the times of intercurrent attacks of bronchitis, pneumonia, &c.—the temperature of the patient is not so high as we would expect it to be from the persistent rapidity of the pulse and the respirations. I have taken a temperature of 100 deg., and a pulse of standing, 172—lying, 144; in a case of phthisis (No. 3,102, Private D.F., 29th March, 1866) of seven month's duration, where there had not ever been any diarrhœa. The observation was taken a fortnight before death. Again, in a case (944, Private D. O., 29th Regiment) which was under my observation for five months before death, the highest temperature I observed was 100·2, whilst his pulse was 154, and respiration 50.

During the first 23 days that this man was under observation, his average morning temperature was 98 deg., average evening temperature 99 deg., and average pulse 100. And herein I find again a confirmation of the opinion which I hold, that tuberculosis may exist without elevation of temperature. At this period of his disease he had had hæmoptysis; his voice was very weak and husky; and the sputa was purulent, but not excessive. His skin was so fair and delicate that a most reasonable assumption from inspection alone, was, that this man was phthisical. This was in June 1866. In July there were small crepitating râles throughout the left lung, and he had a return of the hæmoptysis. In September I find that the emaciation had progressed very much; he was suffering from diarrhœa; that his appetite was bad, and that his temperature ranged from 99·4 deg., to 100·2 deg.; that marked dulness of the left infra-clavicular and mammary regions existed, and that here the râles were larger and more numerous than they were a month ago. The breathing sounds of the right and posterior left puerile in character. Pulse was now almost invariably over 140, and respiration over 40. On the 27th of the month a cavity was diagnosed towards the acromial end of the infra-clavicular left region, gurgling being distinct. On the 28th I find that at 5 P.M. his temperature was 98·8 deg.; and on the 2nd October, temperature, 99·0; pulse, standing, 13—lying, 120; respiration, 52; gastric irritation very great. On the 19th, temperature, 9·8; pulse, 120; and at 5 P.M., temperature, 99·4 deg. On the 20th, temperature, 98·6 deg.; pulse, 112; respiration, 40. On the 22nd I notice, "His average temperature for the last week has been 98·5 deg." He had had severe diarrhœa for some time, and a systolic murmur had become developed. He died on the 23rd, and we made the autopsy 24 hours after death. We found the lungs so adherent to the parietes that both pleural cavities were almost obliterated, especially the left; the adhesions for the most part inextensile, and difficult to break through. The lungs on surface and on section presented innumerable granules of miliary tubercle, closely but separately imbedded in every portion of both organs, excepting a small part of the lower lobes. These granules were prominent, firm, grey in colour, and irregular in shape; the large majority appeared, however, to be round or oval. On section through the apices, a vomica was discovered in each; that in the right was lined by a smooth, apparently pyogenic, membrane and communicated with several bronchial tubes. In the opposite

viscus, the vomica in the apex might have held half an ounce of fluid, bounded superiorly only by the pleura. About an inch below this, and under the acromial end of the infra-clavicular region, there existed a large and multilocular cavity; it was not lined by any membrane, but its wall consisted of broken-down lung tissue. Throughout the two upper lobes, very many anfractuosities were seen. The most careful examination failed to detect a single nodule or tubercle exceeding the eighth of an inch in diameter, nor did there seem to be any fatty or calcareous degeneration; even in the apices, the nodules were grey, firm, and separate. Mitral valves were diseased. Small intestines congested, but no loss of substance.

The above was a well-marked case of phthisis of five months' duration, in which the temperature was always low, frequently normal, whilst the pulse and respirations were very much accelerated. And with this case I will conclude my demonstration that, fully recognizing the value of the thermometer to the clinical observer, it must be admitted great care is demanded of us in the interpretation of the information it affords; and that in phthisis especially we must not be carried away with the idea that the thermometer will enable us positively to say, in a doubtful case, whether the patient is suffering from the disease or not. Its positive evidence is of very great value; its negative evidence must be admitted with considerable reservation.

Hydrate of Bromal.

THERE is a valuable article by Dr. E. Steinauer, of Berlin, in the last volume of "Virchow's Archiv," on the action of the hydrate of bromal on animals and on man. The experiments were made in the Berlin Pathological Institute, and were under the immediate observation of Liebreich himself. The hydrate of bromal, according to the observations detailed, when administered to animals, undergoes a similar change to that undergone by chloral, being converted by the alkalies of the blood into bromoform. But this change goes on slowly, for at the end of an hour and-a-half there was found in the blood in addition to bromoform still some undecomposed bromal. The substance is further oxidized and evacuated in the urine as bromide. The symptoms produced by bromal on animals (frogs, rabbits, guinea-pigs) were first a stage of restlessness, followed by imperfect sleep and anæsthesia, and finally dyspnœa and death with or without convulsions. After large doses, both in frogs and rabbits, the heart was found after death relaxed and distended,—whereas, after smaller doses, it was contracted. In the former case there is probably direct paralysis of the heart by the bromoform, such as occurs after large doses of chloroform. The preliminary stage of restlessness, which has no equivalent after administration of chloral, is ascribed to the action of the bromal aldehyde itself, the decomposition occurring, as stated above, more slowly than is the case with chloral. The author observed a stage of restlessness, after a hypnotic dose of chloral, in a patient suffering under gout, and he ascribed this to the acid state of the blood preventing the usual decomposition into chloroform. With this view he administered alkalis to the patient, and after a few days the same dose of chloral produced the usual hypnotic effect. Proceeding from this, he applied the same principle in his experiments with bromal. Having injected carbonate of soda subcutaneonsly in rabbits, he then injected the hydrate of bromal, and found that the stage of restlessness was entirely absent. The author has administered bromal to man in only a few cases. He has found good effects from it in epilepsy, and in soothing the pains of tabes dorsalis. The method of administration which he has ultimately employed is, first, in the morning and at mid-day a powder containing about 14 grains sodæ bicarb.; then in the evening two to four pills, containing each from ½ grain to 1½ grain of bromal.

Medical News.

A Word for Tobacco.—Dr. A. W. Saxe, of Santa Clara, Cal., in the *Pacific Medical and Surgical Journal*, relates the case of a gentleman who, after abandoning the almost life-long habit of chewing tobacco, was attacked within a year by profuse glycosuria, and who after suffering from this disease for about a year, was immediately and to present appearances permanently cured by resuming the habit. The writer explains the case as "one of vicarious function—the kidneys undertaking to do the work of the salivary glands, and overdoing the matter to a hazardous extent." The fact may be; the explanation scarcely.

Carbolic Acid.—*Nature* tells us that a remedy has been found for the "borer" that ravages Indian and Ceylon coffee plantations, by applying carbolic acid before the eggs are hatched.

Cinchona.—We learn from *Nature* that cinchona culture has now so far advanced in Madras that the Government is preparing to deal with it as an annual crop; and also that the Indian Government has selected the Khond Hills for cinchona experiments. If they succeed the cultivation will be thrown open to private enterprise, with the view of further promoting employment and cultivatien among the Khonds.

Naval Medical Service.—The following were the successful candidates who passed the recent competitive examination for admission into the Naval Medical Service, held at the London University, between the 8th and 11th of August, in the order of merit in which they passed, and the number of marks obtained:—

	No. of Marks
Samuel Haslett Browne, M.D., Queen's College, Belfast	2435
William Henry Colahan, M.D., Queen's College, Galway	2235
Christopher Harvey, Westminster Hospital	1905
Thomas Johnson Alloway, M'Gill University, Montreal	1875
Charles Henry Haines, M.D., Queen's College, Cork	1795
Robert Gilmour M'Calman, M.B., University of Aberdeen	1770
John Campbell, M.B., University of Glasgow	1745
Frederick Taylor, M.B., University of Dublin	1395
Nicholas FitzHenry FitzMaurice, Queen's College, Cork	1325
Frederick William Laslett, Guy's Hospital	1321

NOTICES TO CORRESPONDENTS.

*** Correspondents not answered in the current number should look at the notices in the following week.

NOTICE TO SUBSCRIBERS.—*The Publishers beg respectfully to remind those Gentlemen who have not paid their Annual Subscription, now overdue, that the most convenient mode of remittance is by Post-office Order, or cheque, which should be made payable, in England, to Albert Alfred Tindall; Ireland, Moffatt and Co.; Scotland, Maclachlan and Stewart.*

MR. MORGAN, F.R.C.S.I.—The continuation of your communication, entitled "A new cause of Venereal Contamination," with illustrations, is unavoidably postponed till our next issue.

THE VACCINATION CONTRACTS.

To the Editor of "The Medical Press and Circular."

SIR,—I believe the Profession owe you no little for your manly and commendable efforts in stirring up the Privy Council authorities who rule over the vaccine establishment in requiring all Boards of Guardians to contract with their medical officers under the last Act, and pay them the fees prescribed. I know a very proud and obstinate Board forced to comply since your articles appeared. A *confrere* just tells me of another. Both of us unite, and the body of medical men benefited should join in the cry, of thanking you most earnestly for the work you have so boldly and so ably done. The victory is yours. Every prosperity then attend the old MEDICAL PRESS—the only journal of spirit and independence we possess, and may you long continue to tread the ground the representatives of cliques and parties fear to enter upon, *miserabile dictu*. I am, Sir,

Your humble servant,

Nottingham, Aug. 20th, 1870. JUSTITIA, M.D.

APPOINTMENTS.

ALLEN, P., M.D., F.R.C.S.Ed., Aural Surgeon to St. Mary's Hospital, Aural Surgeon of the Royal Society of Musicians.

BROWN, W., M.R.C.S.E., Resident Medical Officer and Apothecary to the Eastern Dispensary, Bath, vice A. Wm. Coppinger, L.R.C.P.Ed., Resident Medical Officer at the Mineral-water Hospital, Bath.

CARTER, H. F., M.D., Hon. Physician to the London, Brighton, and South Coast Railway Provident Society, vice Thomas B. Phillips, M.D., deceased.

DAVY, R., F.R.C.S., Demonstrator of Anatomy to the Westminster Hospital School.

EAGER, T. C., M.R.C.S.E., Resident House Surgeon at the Westminster Hospital, vice C. M'Cann, M.R.C.S.E., whose appointment has expired.

ELLERY, R., L.R.C.P., &c., of Ridgway, Plympton, Certifying Surgeon of Factories for the District of Plympton, Devon.

GALPIN, Mr. R., House Surgeon to the Royal Berkshire Hospital, Reading, vice Wm. Alex. Slater Royds, L.R.C.P.L., resigned.

MARTIN, E. N., L.K.Q.C.P.I., Medical Officer to the Anglo-American Telegraph Establishment, Newfoundland.

PARMITER, Mr. H., House Surgeon and Secretary to the Staffordshire General Infirmary, Stafford, vice Geo. Rolph Raine, M.B., resigned.

The Medical Press & Circular.

Original Communications.

A NEW CAUSE OF VENEREAL CONTAMINATION — TESTED BY PRACTICAL OBSERVATIONS AND INOCULATIONS FROM A HITHERTO UNRECOGNISED SOURCE — INOCULATION AS A MODE OF TREATMENT.

By Mr. Morgan, F.R.C.S.I.,

Professor of Surgical and Descriptive Anatomy, R.C.S.I.

Surgeon to Mercer's and the Westmoreland Lock Hospitals.

(*Continued.*)

Series No. 8.—*Inoculation from a sore of the second descent from the vaginal secretion of a patient while suffering intense syphilitic intoxication* (Series 3), *on another patient intensely syphilitic—Production of characteristic pustule and soft sharp-edged sore, secreting abundant pus—Immediate relief of the symptoms.*

Patient, aged twenty-eight, No. 1,163, admitted June 7, 1870 ; broken down and thin, having been delivered of a dead child about two months before. Is now covered over with papular rash, and suffers severely from pains.

June 7.—Inoculated from her own vaginal secretion, which was hardly purulent, without result.

June 10.—Inoculated from the pustule of 988, Series 3, the second generation of the vaginal discharge on her own person, producing a characteristic small pustule, with non-depressed centre, having a well-marked sharp-edged ulcer, I have no doubt indefinitely communicable, and in every way resembling a contagious sore.

The alleviation in the symptoms of the patient since the formation of the artificial sore is most remarkable. The rash has immensely improved. She is, however, phthisical.

Series No. 9.—*Primary sore—Double suppurating buboes—Pains—Copious papulo-squamous rash—Intense cachexia and debility—Inoculation from a sore the artificial product of a vaginal discharge—Inoculation from the patient's vaginal discharge producing a sore on another patient.*

Case No. 1,000, admitted March 26, 1870, aged nineteen. Left home ten months ago, and has been since on the town. Only two days before admission observed a sore on the labium. At this date it is large, painful, pus-secreting, and without the slightest induration. There was a tender gland in the left groin.

This gland was leeched, &c., failed to be resolved, and was opened on April 25th, giving exit to a large quantity of pus. I inoculated with this on the side, producing only an abortive pustule.

On April 30 I made a speculum examination, the parts having been before this too sore to allow it. There was not the least ulceration of the vagina or uterus, but some muco-purulent discharge.

April 30—I inoculated from the second artificially-produced pustule of a male patient, the second generation from a sore on the prepuce, but with negative result.

May 2.—A copious rash began to make its appearance over the entire body, and she became profoundly cachectic —in fact, a specimen of syphilitic taint.

At this date I inoculated from her own sore with negative result. The patient continued in a very prostrate and cachectic condition. Tonics, stimulants, good diet, iodide of potassa, iron, and creasote being used.

On June 3 the patient had decidedly improved in general health, but another large suppurating bubo was forming in the opposite groin. I opened this, giving exit to a large quantity of thick healthy-looking pus. I also inoculated the abdomen the same day with this pus, but with a negative result.

June 8.—I inoculated with her own vaginal muco-purulent discharge, but failed, though there was a slight attempt at a pustule.

June 10.—I inoculated from No. 1,118, Series 2. This

produced a pustule and specific ulcer by the 13th, which became a regular chancroid.

June 12.—I inoculated the opposite side from the same source, No. 1,118, Series 2, producing also a specific sore.

On June 15 I inoculated No. 1,098, a strong woman, covered with papular rash, from her vaginal discharge, and produced a tolerable but not well-marked pustule. This same patient, 1,098, was specially difficult of inoculation from other sources. From this date the symptoms steadily improved, the use of tonics and good diet being alone superadded in the treatment.

It is remarkable that I failed, on April 30, to produce a pustule on this patient from an inoculated sore on a male patient, which I produced artificially from a preputial sore; yet, on June 10 and June 12, I succeeded in doing so from the case, 1,118, Series 2, whose sore was the descendant of a vaginal discharge

On July 7 I inoculated from case forming Series 12, producing a well-marked pustule.

SERIES No. 11.—*Auto-inoculation from vaginal discharge—Transmission of the auto-inoculation to other patients—Inoculation from the vaginal discharge almost without a failure—No rash, pains, or marked constitutional signs.*

A girl, aged twenty, No. 1,185, was admitted June 1, 1870, and gave the following history, which has been several times tested, but always with the same result :—

In August last she cohabited with one person belonging to a regiment, with which he left in September. About the first week of September she felt irritated and sore, and got a discharge, but was never aware of a sore beyond irritation. This discharge continued ever since, very profusely, now about ten months. She states positively that she never cohabited since then with anyone, and that about two weeks before admission the labia became swollen while she was hard worked as a servant. On admission there was considerable tumefaction of the labia and a few mucous patches about the posterior part of the vulva, and considerable thin purulent discharge. She has no rash, pains, &c., but she is pallid and cachectic. Assuming the history true, which I have reason to believe it is, (and that the chief annoyance had been the vaginal discharge), I carefully tested its capability of producing chancroids or pustules as follows :—

On June 27, I inoculated this patient on the abdomen, from her own vaginal discharge, producing a most well-marked pustule by the 30th.

On June 27, inoculated No. 669 unsuccessfully.

On June 27, inoculated No. 911 most successfully; now July 4) a regular chancroid.

On June 27, inoculated No. 1,169 most successfully.

On June 27, inoculated No. 1,112, producing a pustule on the third day, and now (July 6) a regular chancroid.

On June 27, inoculated No. 1,098, producing a pustule on the fourth day.

On June 29, inoculated No. 1,098, producing a pustule on the third day.

On June 30, inoculated No. 1,093, producing a pustule in twenty-four hours.

Only two failed of all the inoculations I tried from this case.

June 29th.—I inoculated, from the pustule produced on the patient's own person, on a patient No. 1,167, who had resisted hitherto several attempts at inoculation from other sources, and produced a regularly formed and acute pustule in twenty-four hours; now a chancroid (July 6).

June 29.—Inoculated 1,138 from the vaginal discharge, producing a pustule and sore by the 7th July.

July 4.—Inoculated from her own mucous patch unsuccessfully.

June 29.—Inoculated 921, from the vaginal discharge, forming a pustule which dried up by July 6.

June 30.—Inoculated 1,189, forming a pustule.

Some of these patients had inoculations on them at the time, viz., Nos. 1,112 and 1,093.

Nothing could be more potently inoculable than this discharge; the figure of the resulting pustules was most characteristic. The patient up to July 6 had no signs beyond the mucous patches, but then got a severe gummatous ulcer of the nates. On the other hand, I have inoculated several patients from a case in hospital, suffering from vaginitis and discharge, but never succeeded in producing a pustule or even moderate irritation.

SERIES No. 12.— *Vaginal discharge only—No primary sore — No marked constitutional signs — Inoculation from vaginal discharge.*

No. 1,220.—An uncommonly fine healthy-looking girl of twenty-three, was admitted July 6, 1870. She had been in hospital during the last two years.

On June 1st, 1868, from several soft sores.

On October, 1868,—From a sloughing phagedenic sore of the nates of a secondary character, patches, papules, and finally by ecthymatous spots here and there over the body.

The ulceration was most acute, and was cured by the use of escharotic and local applications.

She remained without a symptom till about ten days before admission, when she got a discharge with some pain and tenderness, and a sore formed, apparently secondary in character, at the cicatrix of the former sore near the nates; the stains left by the ecthymas are still very evident; also a wound on the arm, made six weeks ago presents a deep coppery stain.

On careful examination with the speculum, no ulcer whatever is to be seen, but there is a tolerably thick purulent vaginal discharge.

I inoculated with this on herself, on July 7, producing, by the 11th, a well marked pustule, becoming a sore shortly afterwards.

July 7,—I inoculated No. 1,193—suffering from copious patches, alopecia, and pains—and produced, by the 11th, a characteristic pustule and sore.

On July 7,—I inoculated No. 921 (who was at this time partially under the influence of another inoculation), and produced, by the 11th, a perfectly formed umbilicated pustule. This patient was intensely syphilitic at the time.

On July 7,—Also inoculated No. 988—who was almost free from syphilitic symptoms, having been frequently inoculated, as referred to at Series 3—but produced only a small ill-formed pustule and superficial sore.

July 7,—Also inoculated No. 1,000 (referred to at Series 9), who had already been several times inoculated, and produced a specific, but not vigorous pustule.

July 7,—Inoculated No. 1,075 (referred to at Series 4), and at the time suffering from a vigorous chancroid; produced a perfect pustule and small chancroid.

This case is very interesting, as there was no rash, and the secretion from the sore could not possibly be mingled with the vaginal discharge. The sore had not the character of a primary either in appearance or secretion, and the patient might otherwise have been looked on as a specimen of rude health, but as evinced by the stains and the discolorations left by the wound occurring within two months, together with the reopening of the original cicatrix, the venereal taint was, though latent, still as active as ever.

These cases I have selected from many others under treatment, and where the inoculations have been made so as to test the question of the source of the soft-chancroid, or usual variety of sore. It seems to be essential that the system shall be under the influence of the constitutional poison in order that the vaginal discharge may be capable of producing the characteristic pustule and sore. My inoculations, I think, tend to this conclusion; but I hesitate to pronounce it as a definite rule.

I am compelled to doubt if purulent discharges before the evolution of any constitutional sign may not be capable of producing a sore when inoculated, though I

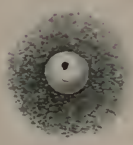
ARTIFICIAL CONTAGIOUS SORES

PRODUCED BY INOCULATION.

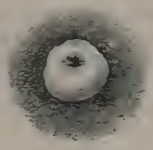
By Mr. MORGAN, F.R.C.S.I., &c.,

SURGEON TO MERCER'S AND THE WESTMORELAND LOCK HOSPITAL, DUBLIN.

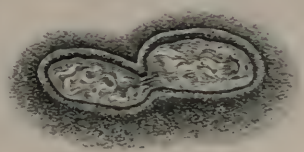
PLATE II.



SERIES 11.
Pustule produced by inoculation from the patient's own vaginal discharge (three days old).



SERIES 12.
Pustule produced by inoculation from the patient's own vaginal discharge (four days old).



SERIES 6.*
Chancroids resulting from the coalescence of two inoculations from a vaginal discharge.

have, as I mention, tested cases of what appeared to be ordinary vaginitis or gonorrhœa, but without success; I have on the other hand inoculated most successfully in other instances, as in Series 12, where no sore or sign was to be found, and the immediate history at the time referrred to gonorrhœa only.

I have inoculated from the mucous patches at the anus of a child two years old, with inherited syphilis, and produced a characteristic inoculation on the side, and from this another on the opposite side; hile in some of the cases detailed, as well as in others, I have inoculated from the mucous patches, but did not succeed. I have also failed in inoculating from large soft pus-secreting pudendal sores, but succeeded in the same instance with the vaginal discharge.

If the mucous patch can be the progenitor of the soft sore, as proved in the case of the child I refer to, and a vaginal discharge, in order to be inoculable and productive of the soft sore, seems necessarily to be coexistent with constitutional symptoms (latent though they may be), it may be reasonably concluded, though contrary to the theory entertained by many authorities, especially on the Continent, that the chancroid or soft sore is not the result essentially of contact with a special virus, or derived from an untainted system, but rather may be developed from the secretions of an individual who is thoroughly under the syphilitic influence; and by its very formation indicates this tainted source.

(To be continued.)

CASE OF PUERPERAL MANIA BEFORE DELIVERY—CRANIOTOMY—RECOVERY.

By R. Harrison Supple, M.B., T.C.D.
Physician to the Collon and Grangegreith Dispensaries.

On the evening of the 18th of June, I got a visiting-ticket for Mrs. W——, of Collon, aged eighteen years, a primapari. When I arrived I found the os uteri dilated to about the size of a florin, the membranes entire, but no pains then; the woman who was with her, informed me she had severe labour all the previous night and part of the day. As she considered her making no progress, and the pains ceasing, she became alarmed, and sent for me. I gave a dose of ergot which brought on the labour again; with the escape of the liq. amnii, the funis presented. In returning it, I found such considerable narrowing of the brim of the pelvis that I considered it a hopeless case for natural delivery or the forceps. Deeming a second necessary, I sent for Dr. McGusty, of Slane; previous to his arrival *mania* came on to such an extent, that she could, with difficulty, be kept in bed, although there was *an entire cessation of labour*. When Dr. McGusty came, he perfectly agreed with me our only alternative lay in craniotomy. So he gave chloroform, and I operated. I never saw so much narrowing in my life, for after I had removed the head, bone by bone, I had to eviscerate, and it was even then with the greatest difficulty I completed the delivery. I think this case fully illustrates the admirable working of the Irish Poor-law System, as, without the able assistance I met with, it would have been impossible to have saved the woman's life.

P.S.—I forgot to mention that the *mania* ceased upon delivery.

ON A CASE OF FRACTURE OF THE LOWER EXTREMITY OF THE HUMERUS THROUGH THE LINE OF JUNCTURE WITH ITS EPIPHYSES.

By Francis E. Clarke, B.A., M.B., Dub., &c.

Apropos of the editorial comment on "*the Bone-setter*" in the number of this Journal for August 3rd, I think the following case may perhaps be interesting to the Profession, and may add another warning to the credulous public of the nineteenth century, who, in every rank of life, seem prone "to lend an ear" regarding matters-medical to the amateur or quack, and occasionally even disregard the advice of a scientific practitioner in order to pursue the *wholesome regimen* (?) advocated by their old friend, Mr. A., or perchance, by the antique Mrs. B., or yet again, by the village *Bone-setter*, or other charlatan who vaunts in the happy termination of the cases which he treats, and of the *success* which eventuates from his skill, until, alas! a death occurring checks his progress for a time. Should this be so? Should ignorance beneath the cloak of hypocrisy he permitted to play with medicine at the expense of human beings' lives? So long as charlatanism or quackery of any kind or degree exists, our voices both individually and collectively should never cease to resound throughout the length and breadth of the land; we should one and all, like true physicians, labouring for the promotion of public health and the public welfare, endeavour vigorously to repress those great and dangerous monsters—medical and surgical hypocrites—

"Sit mihi fas audita loqui; sit numine vestro,
Pandere res alta terra et caligine mersas!"

In the autumn of the year 1868, a boy, aged about twelve years, living in the county Donegal, was thrown when wrestling with a companion, and sustained a compound fracture of the humerus through the line of juncture of the epiphyses of the lower extremity with the shaft of the bone, or, as it is commonly described, an epiphysary fracture of the lower end of the humerus. From the statement of a girl who happened to be present at the time of the occurrence, it appeared that the lad when he found himself falling put out his right arm with a view of saving himself or "breaking his fall," and that his antagonist, who also "got a toss," fell across the extended arm and thus gave rise to the very serious injury which the boy sustained. On being brought home and his coat removed the bone was seen to protrude through the skin. A *Bone-setter* of local reputation and erudite accomplishments (according to his own estimation!!) was sought, and on arrival about ten hours subsequent to the accident "set" the broken limb (with splints which he cut for the purpose) *in a kind of way*, but not, I fear, *secundum artem*. The operation over, bandages adjusted and patient in bed (although necessarily suffering intense pain), the *fearless surgeon*, it being a Sunday and considering, I presume, "the better the day, the better the deed," remarked that he would re-visit his patient that day week. By the sixth day, however, the sufferings of the poor lad had become aggravated to such an extent that "the adventurer's" immediate attendance was requested by his father. The story now may be briefly told: Death put an end to the boy's earthly sufferings but five days after this second visit, the eleventh subsequent to the receipt of the injury. The simplest words which can record the sad end of that sacrificed youth stand as monumeuts of everlasting disgrace not only against the ignorance and hypocrisy of *the Bone-setter*, but against society at large which tolerates in its own credulity a state of affairs at once as lamentable as it is disgraceful.

Oh! ever loving, lovely and beloved!
How selfish sorrow ponders on the past,
And clings to thoughts now better far removed!
But Time shall tear thy shadow from me last.
All thou couldst have of mine, stern Death! thou hast.

On the fifth day after death and second after interment, the body was exhumed by order of the coroner, and an autopsy made at which, I being present, assisted. On superficial examination, a large external wound was to be seen in the anti-cubital fossa through which the lower end of the upper fragment could be felt projecting, but it did not protrude beyond the edges of the wound. From upwards of an inch above, the entire forearm and hand was extensively gangrenous, so much so, that it was impossible to make an accurate dissection of the soft parts or to determine the state of the vessels or nerves in the neighbour-

hood of the fracture. The body, had in addition, undergone great decomposition. When the wound was extended both above and below by incision the continuity of the entire shaft of the humerus was found to be complete, and contained the two condyles in an uninjured condition; it was devoid, however, of the two eminences which form respectively the trochlea and capitellum and articulate with the two bones of the forearm. The upper fragment then was the entire humerus merely denuded of its inferior epiphyses; the lower, those epiphyses themselves. The lower end of the upper fragment was nearly at the external orifice of the wound and directed forwards, and including, as it did, the two condyles, was broad with an extremely roughened, jagged, and uneven extremity. The epiphyses alone constituted the lower fragment, and still continued united together in one piece and attached by the ligaments of the joint to the bones of the forearm, so that the articulation proper remained normal; the upper extremity of this fragment was directed backwards and outwards. On measuring the arm before dissection, I found that there was slight shortening as compared with the other, but the normal relation of the olecranon process to the condyles was lost.

The case in a surgical point of view is one of much interest, the injury being on the whole rare, until within a few years past unrecognised, and dissections of it recorded by no means numerous. When a student I had the advantage of seeing a case of it treated in Sir Patrick Dun's Hospital, by Professor R. W. Smith, who still adorns the Chair of Surgery in the University of Dublin, and to whose class I feel a just pride in having belonged, and I have heard him with that eloquence, succinctness, and accuracy for which he is distinguished, enunciate in his admirable lectures on fractures and luxations, the signs both general and diagnostic of this remarkable lesion. It was he indeed, who first described it,* and quickly did I perceive the similarity even in its very aspect between the injured arm of that lifeless corpse lying in its coffin by the side of its "narrow bed," and the arm of the boy whom I had previously seen in Sir Patrick Dun's, in whose case, if my memory serves me, the accident originated from a fall off a donkey upon which he rode; and vividly did I remember the striking remarks of Professor Smith regarding the signs of the injury—the great transverse breadth of the anterior tumour caused by the retention of the two condyles in the lower extremity of the upper fragment and the two osseous tumours posteriorly, both of which signs serve to distinguish it from a supra-condyloid fracture of the humerus which it much resembles, not only from the facts of shortening and anterior osseous tumours being present in both lesions, but also because the antero-posterior diameter of the arm is increased likewise by each form of injury. It is also to be borne in mind that the normal relation of the three bony projections at the back of the elbow was disturbed, the olecranon being above the condyles, a fact which also serves to distinguish this epiphysary fracture from a supra-condyloid fracture, but which causes it to resemble much a luxation of both bones of the forearm backwards, a surgical lesion which Professor Smith likewise pointed out as liable to be confounded in diagnosis with this fracture of the humerus through the line of juncture with its lower epiphyses if the important differential signs of the signs of the latter be not accurately attended to. The two tumours posteriorly in an epiphysary fracture, being the head of the olecranon and the end of the epiphyses, are nearly on a level, but those caused by a dislocation are fully an inch one above the other, as they are formed by the olecranon and of the radius respectively. With regard to the former that learned gentleman, moreover, reminded us that the centre of ossification of the capitellum is developed much earlier than that of the trochlea. The direction which I found the lower fragment had assumed we may naturally infer was caused by the action of the triceps muscle.

In conclusion, I may add a few words regarding *the Bone-setter*. The imperfect state of legislation on the question and the sympathy of a local jury saved him from punishment which he so well deserved. He escaped without one single wound, save, that it might be he possessed even the minutest scintilla of the "*mens conscia recti*," and that a tortured conscience laden with remorse poured upon him in reality a retribution fiercer than any which a judicial tribunal could have enforced. It is perfectly possible that the man may have "put up" the fracture with as much care as he could bestow, but his ignorance of the nature of the accident and of the legitimate principles of surgery rendered it impossible for him to meet the exigencies of the case as skilfully as its complicated nature required; it is also very likely that he really did consider the case a trivial one when he decided on postponing his second visit for a whole week, and that he may have done so with perfect good faith is not at all improbable, but the old French proverb was only too sadly verified, *L'homme propose mais le bon Dieu dispose*, and the unfortunate victim fell a prey to his ignorance and self conceit. The lesion was not diagnosed; the bone protruding not thoroughly reduced; the fragments not placed in apposition; the external wound not attended to or its edges approximated; the bandages so tightly adjusted as to increase the suffering; and the injured limb left then for days and days (unexamined and unattended to) *literally to rot*—as, indeed, the *post-mortem* examination showed it did. Is it not time that this remnant of a barbarous age "*the Bone-setter*" should be finally extinguished? Now that hygienic and sanitary measures have so materially diminished and mitigated disease; now that the sewage and other grave questions are being discussed for the prevention of contagion; now that Irish physicians, stimulated by zeal and by the vigorous and hearty exhortations of the Poor-law Commissioners, have "stamped" variola from their land, and that as nearly a happy result in this direction has been obtained in the mother country, should we not repel *the Bone-setter* with the disastrous consequences of his ignorance once and for ever from our shores? May we soon see the last of him! May the efforts of the Medical Press and Circular, which ever holds up its head honourably amongst its contemporaries, prove successful towards his final extinction! And may my professional brethren at all times manfully assist!

* Malgaigne, Vidal, and other writers, appear to have previously mistaken its diagnosis by not drawing the distinction between fractures *below* and those *above* the condyles.

Transactions of Societies.

BRITISH MEDICAL ASSOCIATION.

I.—The Audacity of Modern Surgery.

You, gentlemen, among whom are some of the most intrepid operators of the day, will have no difficulty in recalling examples of the audacity of modern operative Surgery. You know that the boldest exploits recorded in Surgical annals have been repeated but recently; that, in obstruction of the gullet, the stomach has been opened and the patient fed through the opening; that the kidney has been cut down upon, and stones taken from it; that the aorta has been tied; that the removal of the whole upper extremity (the shoulder-blade and part of the collar-bone, together with the arm), either on account of accident or of disease, has become a not unfrequent proceeding. Upon the table before you there is perhaps as large a mass as has ever been taken away, along with the upper extremity—an immense enchondroid tumour. You know that operations which but a few years ago were counted unjustifiable, such as ovariotomy, are now established on the firm basis of success; that feats even more startling, which might even make the initiated tremble, have been undertaken in isolated or comparatively rare instances, and with a fortunate result; that the spleen has been taken away, the kidney extirpated, as a sequel to ovariotomy; and, not to multiply examples, that the uterus has been removed several times alone, and

also together with a large cyst and all its diseased appendages, constituting a large mass.

But it must not be supposed that, because these great operations are cited as illustrations of the audacity of modern operative Surgery, they have no other claim to our admiration. Many of them are successful endeavours to save life under the most unfavourable circumstances; and none were undertaken but after a patient investigation of facts, or without a careful and judicious consideration of all the aspects of the disease and of the condition of the patient. All were performed according to sound Surgical principles, and for the removal of disease in itself necessarily fatal.

Nor need our admiration of these or similar undertakings engender in our minds a recklessness of human life, any more than their execution indicates the existence of such a feeling. It is, indeed, sometimes said, and even by members of our Profession, that the performance of such operations does evince a certain want of respect for life, and that great operators are apt to look lightly upon the deaths of patients where a fatal result ensues. For my part, I entirely repudiate such thoughts, nor do I believe in their existence; and I would appeal to every operator in the room to echo my opinion, and to say if he would not deprecate such a feeling as the worst foe to a really sound operative Surgery.

But if in our own ranks there are those who believe in such recklessness, we cannot be astonished that we sometimes hear opinions in the same sense expressed by individuals of the non-professional public, and the very virtues of the Surgeon, his coolness and self-possession, brought forward to attest his callousness to the sufferings of others and his disregard for the sacredness of life. No accusation could be more unjust. Because, Sir, when the Surgeon puts his knife into the palpitating flesh his hand does not tremble, nor the sight of blood affect his nerves, should he be stigmatised as cruel, heartless, and unfeeling, or regardless of human life? Surely not. This presence of mind is the result of knowledge, not of callousness—of knowledge based on experience, and of forethought. It is the result of a well-devised plan of operation. It is indeed, the result of a true sense of the sacredness of human life, and of the deep responsibility that attaches to him who places his patient's life in possible immediate jeopardy, to rescue him from a certain but instant death. Without such a feeling, no man ever was or will be a truly good and successful Surgeon; for more than aught else—more than the love of fame or the desire of success—it impels us to those measures of precaution, of careful preparation, of minute detail, which enable us to bring to a fortunate termination the most hazardous proceedings, and thus to justify the audacity of modern operative Surgery.

II.—The Conservatism of Modern Surgery.

The term conservative as applied to Surgery is quite of modern origin, and dates from the year 1852, when it was first made use of by Sir William Fergusson. The conservative spirit, however, influenced the practice of Surgeons in much more ancient times, as we know from the works of Paulus Ægineta, who distinctly speaks of the excision of the joint-ends of bones, and of the removal of entire bones in lieu of the amputation of the limb.

The story told by Garengeot of the man whose nose, having been bitten off in a drunken quarrel in a wine shop, fell into the kennel, was picked up, washed, and re-applied to the face and grew there, can scarcely be quoted as exemplifying conservatism in the special sense which has been given to the term in recent years. A predecessor of mine in this town, some fifty years ago, acted quite within the strict meaning of the term when, in a case of compound dislocation of the ankle-joint, where certainly most Surgeons of that period would have amputated the foot, he merely removed the astragalus and saved the limb. The gentleman who had the good fortune to be the subject of this, at that time, somewhat unusual act of conservatism, was afterwards well known to me, and walked with only a very slight halt. Another Newcastle Surgeon, who, I am happy to say is yet hale and well, practised the excision of the os calcis sometime before the mention of the phrase by which we would now characterise the operation.

It is, however, since the publication of Sir W. Fergusson's paper that the attention of the Profession has been more thoroughly roused and directed to this principle in Surgery, which, during the last ten or fifteen years, has been more and more widely acted on, and is now so completely established as to be one of the most marked characteristics of modern operative Surgery.

The removal of diseased joint-ends of bones is at present one of our most common proceedings, and has gradually been applied to most of the articulations in the body. The excision of the separate bones of the tarsus and carpus, and of the whole shaft of long bones, is not less frequent; and even such bones as the shoulder-blade and collar-bone have been several times removed, the extremity which they support being preserved.

It is interesting to note the advance which has taken place, in a conservative direction, in the method of performing resection, itself the stronghold of conservatism. The external incision, at first more or less complex, has been reduced in most situations to a linear and less extensive one; the amount of bone thought necessary to be removed is less; and recently the practice of subperiosteal section has been adopted, by which an important structure is preserved and reparation favoured. After excision by this method we rarely meet with those cases of withering, the result of too extensive removal of parts.

Even in what we might call the hostile territory of amputations, the same principle is at work, leading us to remove limbs at points as far distant from the trunk as possible, as in the amputation through or immediately above the ankle-joint, instead of below the knee, and through the knee instead of at the middle or lower third of the thigh. Few amputations are followed by a more satisfactory result than that through the knee-joint, when done so as to leave an anterior flap to cover the end of the bone, from which the articulating surfaces need not be removed. The wound heals rapidly; no raw surface becomes exposed; and a shapely useful stump is the result. These conservative amputations possess several advantages, since they not only leave a more serviceable stump, and interfere less with the symmetry of the body, but they also increase immensely the patient's chances of life.

The cast upon the table was taken from the thigh of a young woman whose recovery would assuredly have been much more doubtful had amputation through the mid-thigh been resorted to. Her leg had been frightfully mangled in a steam threshing-machine, and the bones broken into small pieces up to the knee-joint; a quantity of blood had been lost; and, when seen, she was in such a condition of collapse that the propriety of an operation seemed doubtful. It was just possible to obtain an anterior flap to cover the end of the femur; and, death otherwise certain, amputation through the knee was done. The pulse afterwards was barely perceptible, and for thirty-six hours it seemed most unlikely that life should be preserved. Subsequently she rallied, and restoration to health was ultimately rapid. She was able to be out of bed in fourteen days, and the stump entirely closed in a very short time.

A peculiar signification is given to the term "conservative" by Sir W. Fergusson, who uses it to designate those operative measures by which limbs or other parts of the body are more or less completely preserved. Such proceedings as have been already mentioned come strictly within this meaning; so, too, would some of the modern operations for the removal of growths from the jaws and the neighbourhood of the orbit. Malignant growths occupying the ethmoid cells and displacing the eye outwards, as well as exostosis springing from the os frontis, may be extirpated by means of a proceeding which preserves the nasal bone, and, as a consequence, the contour of that important feature the nose. This bone is raised up along with the skin covering it, so that it may be laid down again in position after the operation and preserved; the only structure absolutely removed along with the diseased growth, in addition to portions of the ethmoid, being a part of the nasal process of the maxillary bone. The mark left after this measure is exceedingly trifling.

The treatment of an ordinary compound fracture could not be looked upon as fully within the meaning of conservatism in Surgery; but I know no other term which can adequately describe the carrying through to a successful termination a case of such aggravated injury as would raise the question of the propriety of amputation.

There are, perhaps, few questions in Surgery which afford a greater test of judgment, experience, and decision than that which we have to ask ourselves in certain cases of injury—Shall this limb be removed or not? When the question has been answered in the negative, there are also few cases which afford a greater test of our patience, perseverance, and readiness at expedients, watchfulness, minute attention to details, and capability of using mechanical forces.

(To be continued.)

SPECIAL CORRESPONDENCE.

[FROM OUR OWN CORRESPONDENT.]

PARIS, 24th August, 1870.

SOME persons recently have made many complaints concerning the organization of military ambulances, or international ambulances. After examining what they say, I am obliged to believe the assertions to be full of exaggeration. The lazy manner in which all the devotion placed at the command of the administration has been utilized is owing to a circumstance which is too generally ignored, —viz., that in the late affairs the majority of the ambulances, with their officers, have been taken prisoners by the Prussians. Thus, M. Legouest, the surgeon at the head of the first corps, had lately no news of his ambulance ; and we hear that a surgeon of another has been in the same plight. Several towns, where hospitals have just been set on foot by Professor Layeran, have fallen into the power of the Prussians, and from one of these that gentleman left as it were by one gate, whilst the Prussians entered by the other. We must reflect that affairs are not now as they were in the Italian War ; surgeons were then wanting, because the victorious army marching forward, picked up all its own wounded and a part of those of the enemy ; but it has happened very differently in the French retreat lately, and we don't believe that the number of wounded taken up by the French has exceeded 2,000. Now, there are in the army more than 600 military doctors, and, for this reason, persons in power have not been in a hurry to send to the Seat of War (as has been suggested) all doctors, without exception, belonging to military hospitals. At present, some of these remain in Paris, such as MM. Colin, Godellier, and Villemin, whose departure, it is true, will take place, probably very shortly.

For the same reason, the students inscribed at Val-de-Grâce have not been able to find employment in Paris. The number of those inscribed is about 1,700, but, in consequence of absence and different reasons, there are about 1,000 disposable. Now this is twice or thrice as many as there are wounded in our hospitals. There are only sixty wounded men in the Val-de-Gráce. There is, however, a supposable case in which we ought to reject the entire want of movement of this reserve of ambulances, and this would be if a certain number of the wounded tended in private houses, near the Theatre of the War, should be in need, as M. Nélaton is reported to have said, of sufficient care. In such a case, the zeal of the military doctors fails, because *they* are obliged to follow the motions of the corps ; but, on the contrary, it is here that the volunteering ambulances can render the most effectual service, if there are sufficient servants to attend to the sick.

The Minister of War has just decided that all the doctors and apothecaries inscribed on the lists of the Hospital Val-de-Gráce, after the examinations which have just taken place, are to be retained in Paris, or in the localities where they may chance to be actually residing ; and, consequently, whether they may be National Guards ("Mobiles"), or called out by the last Act, they are not to be sent to the places indicated in that Act. Two large rooms in the Auction Rooms in the Rue Druot are said to be full of old linen, to be used for making *charpie*. I hope it may not be frequently contaminated by small-pox patients. M. Hoüel, a Professor attached to the Faculty, conservator of the Dupuytren Museum, set off a few days ago with several pupils and young doctor volunteers to help in operating and dressing the wounded.

MM. Hardy and Guibout, two of the physicians at the Saint Louis Hospital, have been charged with the medical service of the military hospital, Saint Martin. M. Ricord subscribes 200 francs a month, so long as the war lasts, to the *Secours aux blessés ;* and Dr. Buisson, Dean of the Faculty, has abandoned to this society his honorarium as long as the war lasts, amounting to 1,500 francs a year— from all of which you see how good and generous our brethren are here as elsewhere to the poor and afflicted.

M. Bazin mentions a piece of diagnosis between disease of the nostrils arising from syphilis and scrofula, which will be, I am sure, felt to be very useful by practitioners. He says that syphilis destroys first of all the bones and cartilages of the nose and of the palate before touching the integuments, whilst scrofula does not reach the bones before it has first destroyed the superficial parts. This is very practical. The question has often been mooted whether consumptive persons ought to marry, or rather to procreate children. These two ideas are, of course, in Paris, easily separable ; although in other cities they would seem to be considered identical terms. Dr. Virchow, in some recent observations on the subject, translated into one of the French Medical journals, is reported to have said that in the first place, although it certainly frequently happens that the offspring of consumptive parents are consumptive, yet this is not *always* true. Next, consumptive persons, although they die young, are often as intelligent and often as great geniuses as any other class of men. We must all die of some disease or other, says Virchow, and why not of this as well as another ? I cannot say that these reasons convince me, and I must add that I hold that most consumptive parents ought either to have no children or the minimum number. And, I may say, too, that parents who have syphilitic poison in their frames, are often in very much the same position. It must be remembered that delicate children, such as those produced by consumptives and many syphilitic parents, are often no great pleasure to their unfortunate parents, but rather a burden and a drag on themselves and their relatives. This is opposed to the happiness of the greatest number.

I see that M. Alfred Fournier, who is now the successor of M. Ricord as a writer on syphilis, has brought out a work on the writings of Fracastor, with annotations of his own. I have not read the work, but hear it highly spoken of. The magnificent photographs of skin diseases brought out in a lithographed form by Dr. Hardy, of the Hospital Saint Louis, are now out of print. Their price was sixty francs, and there is, I hear, to be another edition. At this moment, scarcely any books are sold, as I was informed by M. G. Baillière the other day, Nothing is read but the "*Dernières nouvelles de la guerre.*" I hear that, among the comparatively few wounded soldiers at present in the Val-de-Grâce, the most of those wounds are struck in the lower extremities—very few in the chest. My informant, a young British subject, added that he supposed this was owing to the fact that the Prussian needle-gun does not carry so far as the French chassepot. I am so entirely ignorant of warfare, Mr. Editor, that I cannot judge whether this is a true account of the fact or no. Can you ?

M. Alfred Fournier gave, in one of the Medical Societies of Paris recently, an account of a case of syphilis, where the primary sore had been contracted fifty years before the occurrence of some tertiary lesion. This proves two things :—(1) That people once tainted with constitutional syphilis are never quite certain to be free from relapses however long they may live ; and (2) That syphilis may remain a very long time without much mischief being done to the ordinary health of the individual. This long period of freedom from attacks of tertiary syphilis is, I should think, one of the most remarkable on record. This is a very bad season for the watering places of France. Most of them are reported to be entirely abandoned by the Parisians, who naturally desire to be in the Capital, in order to receive the last notices of their poor male relatives, so many of whom are being slaughtered in this dreadful strife. Wherever you go—into whatever hospital you stray—a great proportion of the male patients are going off to the war. If this goes on much longer, there will be a serious loss of the adult male population in France. But this may, on the other hand, be advantageous to many poor women who have, as you know, so few lucrative employments even in this city. Waiters and drapers' assistants are going off in shoals to their doom. I presume their places will occupied by women, and that prostitution will

then become a little less common in this strange mixture of good and bad people—Paris. In the wars of the former Napoleon a great number of men perished ; and thus women got a little more share of the good things of this life, than they do in most countries, and notably Germany, where they are as yet mostly household drudges. But, even here, there is an immense deal to be done before the grand excuse for prostitution, destitution of the weaker sex, is taken away. To this effect, consult the work of Lecour published this year.

I trust in a future letter to give you some account of lectures "On Diseases of the Heart," recently delivered by Dr. Peter at the Hôpital de la Pitié. At this moment, of course, all is quiet in the lecture room. The Sorbonne, the College de France, and the Academies of Medicine and Law, are all deserted. May the students soon meet in better times, when sweet peace again settles on this distracted land ! I was never so convinced as I am now that war is the greatest of all human errors and crimes. It breaks the heart of mothers and fathers, and plunges us all here into the direst affliction.

The sixth ambulance of the *Société de Secours aux blessés* has been ordered to depart immediately, and is to be sent to Epernay in Champagne, the railway being only open as far as Chalons. No instructions have been given to it, and, of course, this ambulance must endeavour to find out the Army by itself, as no telegrams have arrived for some days from Marshal Bazaine. Doctor Pietrowsk is the chief surgeon, and there are four surgeons, eight assistant-surgeons, seven sub-assistant surgeons, one Catholic clergyman, and one Protestant pastor, one major-infirmier, and sixty-one under-servants. All these men are young, ardent, and the assistant surgeons are all doctors of medicine, many of them being old *internes* of the Parisian hospitals. There is talk of the speedy creation of a sedentary ambulance at Paris, formed by the funds subscribed by the Parisian Press. Dr. Ricord and Monseigneur Baüer are to be the chief directors. From three to seven o'clock yesterday fifty-three doctors wrote down their names as associates at Ricord's house. Seeing the great number of names which are sure to pour in daily, to judge of what took place yesterday, M. Ricord has said that, besides the sedentary ambulance composed of 200 beds, they ought to create in each quarter companies of doctors, whose duty it should be to visit the wounded in private houses, and who, in case Paris should be besieged, should organise, on all points attacked, flying ambulances, destined to receive the wounded, and to afford them the first cares before sending them to the sedentary ambulance.

The ambulance of the first division of the First Corps of the Army was established at Frischwiller, in the *mairie* near the Church. On the 6th August, the day of the bloody battle which was engaged against the corps of MacMahon, this building, which ought to have been respected, on account of its white flag, was fired at from eight in the morning until half-past four in the afternoon. M. Rodet, the military *sub-intendant*, together with the members of the staff and administration of the ambulance, neither wishing or being able to follow, under any pretext, the division which was in retreat, remained in the town. The ambulance gave asylum to 580 French and 40 Prussians. At half-past four o'clock they were all made prisoners by the Prussians. Two of the servants also were killed as they were taking a wounded Zouave into the ambulance ; and Dr. Milliot was killed as he was bandaging the wounds of one of his patients. The ambulance of the French Press also was made prisoner, and both of these ambulances met each other at Cologne. The members of the first division reached Paris on Saturday last. Evidently they ought not to have been taken to Cologne at all. You thus see that there are dangers to our devoted brethren in charge of the wounded soldiers.

Lord Derby made a capital speech on sanitary matters at the opening of the new hospital at Bootle last week.

THE SEWAGE QUESTION.

SPECIAL REPORT.

(Prepared expressly for the Medical Press.)

No. II.

ALDERSHOT SEWAGE FARM.

The farm lies to the north-east of the two camps, and it consists of about 112 acres of land, of which 89 are under cultivation ; of these about 46 acres are laid out for Italian rye grass, and 2 or 3 acres for rhubarb, which, we are informed, nobody will eat a second time, on account of its rank sewage flavour.

The soil consists of very porous sand, with a ferruginous subsoil. The sewage amounts to about 200,000 gallons a day. It comes from the north and south camps, where there are about 10,000 soldiers, with a supply of about 20 gallons a head daily. It is a strong sewage representing the pure sewage of an adult population with no manufacturing operations. It flows from the camp for a distance of nearly two miles through eighteen-inch earthenware pipes, with an average incline of 25 feet in a mile, but the incline is not regular and the pipes are too large, and the scour is not good. When it arrives at the head of the farm it is discharged from the two pipes into a common open channel, which delivers it to the subsiding tank, with a coarse contrivance for straining the sewage by an upward flow through perforated planks, and then it runs over a weir into the channel which conveys it to the carriers from which it flows over the land. The solid matters which are strained off from the sewage are conveyed to a pit where they are mixed with gas lime and other refuse matters, and are then used for manure ; but the amount of solid matter thus kept back is not large, for in twelve months it only amounted to about 300 tons in its wet state.

At the time of our visit, the farm was in a very offensive condition, for although the great bulk of the sewage was not flowing upon the land at all, but running bodily into the Blackwater stream, yet the remains of previous irrigation were lying about in cakes of partially dried fœcal matter, which would be washed away into the nearest streams and ditches by the first heavy shower of rain. The ground was everywhere sodden, and stinking, and the rye grass was dying out, and the usual rank water grass taking its place.

At the lower part of the farm there is a military or occupation road which bounds the farm, and on the opposite side of the road are a few cottages and beer houses, the inmates of which complained bitterly of the frequent stenches from the farm, the sewage of which flowed into the neighbouring ditches and ponds, and thus rendered the place a stinking swamp. Most of the sewage at the time of our visit was running from the farm across the road, and either going at once into the Blackwater stream or running upon the meadows behind the houses. At the places where the sewage was running into the Blackwater stream the bed of the river was silted up with the solid matters of sewage and rendered most foul and offensive. Samples of the sewage (No. 1.) were taken from the head of the farm as it came from the camp, and (No. 2.) after it had been strained, and (Nos. 3, 4, 5, and 6) as it was flowing from the farm to the Blackwater stream from four of the outfalls.

A sample of the Blackwater stream (No. 7) was also taken immediately before the entrance of the foul sewage water from the farm into it; and the following are the results of the analysis of the several samples :—

Constituents per gall.	No. 1.	No. 2.	No. 3.	No. 4.	No. 5.	No. 6.	No. 7.
	Grs.	Grs.	Grs.	Grs.	Grs.	Grs.	Grs.
Solid matter in solution	53·93	53·73	51·67	52·47	58·20	54·13	18·93
Chloride of Sodium	14·92	15·36	16·98	17·08	24·01	20·64	4·12
Organic matter	30·01	31·70	27·89	24·21	20·69	22·10	3·56
Ammonia	7·54	7·54	6·40	6·40	5·04	5·12	0·18
Ditto Organic	0·94	0·94	0·56	0·64	0·48	0·48	0·08
Nitrogen as Nitrates, &c.	0·00	0·00	0·00	0·00	0·00	0·00	0·26
Oxygen required to oxydise	4·38	4·40	4·20	3·81	3·30	3·61	0·35
Matters in suspension	43·77	35·01	3·84	25·91	6·14	4·80	2·68
Organic matter	29·75	26·24	2·18	12·28	1·98	3·22	0·69
Mineral ditto	14·02	8·77	1·66	13·63	4·16	1·58	1·99

These results show that the so-called purification of the sewage by irrigation was merely a pretence, for the soluble constituents of the sewage were but little improved by the process, the organic matter of the effluent water being still over twenty grains per gallon, and the amounts of suspended matters also considerable. In a sanitary point of view, therefore, the process was highly unsatisfactory, for not only was the sodden sewage ground evolving a most offensive odour, which the inhabitants said was sometimes most sickening, but the effluent water was still a strong sewage, polluting the ditches and watercourse to such a degree as to render them a most serious and dangerous nuisance.

Considering how highly the Royal Pollution Commissioners had spoken of this Aldershot Farm, and of the success of the process,* we were not prepared for the shocking condition of things which we witnessed.

We have no means of ascertaining the commercial facts of the case, but if any sewage farm can ever be made to pay it must be in such a case as this, where both the land and sewage are given to the tenant for a peppercorn rent.

Next week we shall report on the

WARWICK AND BANBURY SEWAGE FARMS.

Analytical Records.

NEW PREPARATIONS.

WE received a few months ago a few samples of Long's Solution of Pepsine in Glycerine and some bottles of Long's *Liquor Ergotæ*, manufactured by Hamilton, Long and Co., of Dublin. The former preparation we found exceedingly useful in cases of impaired digestion and mal-assimilation. We exhibited the drug in form of mixture in combination with dilute nitro-muriatic acid, and the effect obtained was most satisfactory.

It is directed that this solution of Pepsine be administered *after* meals; our experience is—and those who employ it, we think, will observe the same—that it is more efficacious if given *before* eating; that it will thus hasten in a marked degree the process of digestion. We have great pleasure in recommending it as a most valuable preparation. The reliable efficacy and power of Mr. Long's Liquor Ergotæ, we believe, is already established by physician-accoucheurs and others. We can only assert that we found it active and certain in producing the effects of ergot, whilst the nauseous objection to the drug is overcome by reason of the sweet and palatable form in which Mr. Long's preparation is made. We regret, however, to learn Hamilton, Long and Co., knowing, we presume, the value of their latter medicine, have thought fit to patent it. A two ounce bottle purchased from, and obtained through, the Messrs. Herrings, bore the Government stamp. This will increase the price of the preparation, and put it out of the power of the general practitioner to keep it. Allowing the therapeutic value of these two preparations, we hope the eminent Dublin firm of Hamilton, Long, and Co. may be induced to give these medicines at a fair remunerative price, and that they will not deprive the general practitioner engaged in extensive obstetric practice of possessing the latter drug, because, owing to its present price, those gentlemen who use much ergot would find it amount to a serious item at the end of the year. This is our only objection, otherwise we have great pleasure in introducing to the notice of the Profession, and strongly recommending to them, *Long's Solution of Pepsine* and *Long's Liquor Ergotæ*.

THE editor of the *Union Medicale*, in his last issue, makes his lament in doleful strain. He says :—"We would have desired to have placed our humble residence at Chantillon at the disposal of two wounded officers, who might thus have enjoyed the most healthful circumstances. We are prevented from making the offer by the fear of the investment by the enemy of that part of the suburbs of Paris. Chantillon is situated exactly between the fire from the forts of Vauves and Montrouge. If they were attacked by the enemy these forts would bombard my poor house, and the wounded therein, as well as those who were taking care of them, would be no longer safe.

* "In this case the extreme natural poverty of the soil does not seem to have been a hindrance to the efficiency of the process of cleansing by irrigation. The farm, *well managed*, is covered with a capital plant of vigorous growth, to be fed by the filthy water, which accordingly is greatly purified by the process. * * *

"The Aldershot Farm appears the more satisfactory as an example of *the sewage nuisance abated*, at the same time that its filthy contents are converted into valuable produce, from the circumstance that a previous attempt to deal with it by subsidence and filtration tacitly had been a complete failure."

First Report of the Commissioners appointed in 1868 *to inquire into the best means of preventing the pollution of rivers.*—p. 78.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, AUGUST 31, 1870.

THE WAR AND ITS LESSONS.

"Medical men, like priests, have no right to be politicians." It has long been justly felt to be highly important that some persons in all countries should devote themselves to the welfare of the whole race, and not only of that portion of it which is for the moment under the same government. The Christian religion has ever taught that all men are brethren; and in no case is the teaching of this sublime fact felt to be more true than when it is applied to the case of the sick. Anatomy and physiology have revealed to all who are members of the noble art of healing, that the differences between Germans and French, or between English and Russians, are but skin deep. The rate of the pulse is a constant quantity in all European countries,—the length of life and many other facts of our natural history are equal in most States. Everywhere man has the same appetites of hunger, thirst, exercise, repose, or sleep. Hence, the medical observer is sometimes at a loss to conceive why European nations should object to leave each other in the tranquil enjoyment of the means of satisfying the imperious demands of these appetites as far as their conquests over external nature will admit.

In former days, it was the priesthood alone who were supposed to be sufficiently imbued with the spirit of Christian brotherhood to be allowed to accompany armies without taking an active part in the conflict. Modern civilisation has made a great step in advance in adding to the list of those who are to be allowed to be present as non-combatants at these sad scenes of butchery, our modern battles, the members of the medical profession. It is, indeed, a kind of *reductio ad absurdum* of the whole theory of modern warfare when we see that the sole object of hostile camps is to disable each other for the moment from fighting, not the further suffering of the combatants. In days gone by, all kinds of cruelties took place after the battle was over. Soldiers revelled in murder and rape for days after a victory. Who, then, shall say that human nature makes no progress, when we hear so much, at this terrible hour, of the benevolent and arduous attempts everywhere made by members of our Profession to mitigate the miseries of the soldier in the field and after the battle is over?

Although patriots, we are, indeed, no politicians in the narrow sense of the word, which makes men love their own country alone, and count the citizens of all other nations as aliens. Medical art is ever ready to succour all members of the race. Medical science finds too little difference in the construction of the human frame in various countries to require any peculiar set of precepts of art to be carried out in different countries. The great Virchow is a renowned physician in Paris or in London. Nélaton is as great a favourite with ourselves as he is in Paris. The illustrious Jenner has a statue in France, although, alas! he is neglected in aristocratic London. Laennec's memory is as much loved and revered in Dublin, as it is in St. Petersburg or in Berlin.

The truest of all democracies is the medical fraternity. It is a republic, like that of letters; and the chief men in our Profession are those who are the inventors of some agent, such as chloroform, which shall free the whole race from needless suffering; or the discoverer of some new remedy or application against mechanical or physiological injuries. Our Simpsons, our Velpeaus, and our Trousseaus have mostly worked their way to fame from the ranks; and, although practice and the emoluments of the Profession are doubtless often the lot of the least scientific of our brethren, still the man of real utility as a discoverer in medical science is sure to be recompensed by some modest professional reward. We hold, then, that it is one of the most encouraging signs for the future destinies of our somewhat unfortunate race that the same honour which, for so many centuries, has been granted to the clergy, is now to be shared with the doctor.

For, after all, depreciate as you will the human frame and its necessities and abilities, it is all that we have. Without the integrity of the brain, where would be our thinkers? Without a healthy heart or lungs, what is human life? Certes, it is not in these days of accurate anatomical and physiological research, that it will any longer be found possible to talk slightingly of the doctor's *mission*.

The aims of medicine are the sublimest of all human aims. The true physician, or, rather, generally, the medical student, belongs to all countries. Everywhere he sees, with interest, the wonderful construction of the human frame, endeavours to penetrate into the arcana of life, and to discover what militates against health. Medical men are, of all men, the most fit for fraternity and equality. They learn to judge their fellow-man, not by some superficial qualities he may chance to possess, but by the deepest of all criteria, those founded on constitution and temperament. Many persons say that this Franco-Prussian war is likely to be one of the last fought in Europe. Would that this were likely to prove true! We ourselves are too anxious that it may be a correct prophecy to be good judges of the truth of the saying. But of one thing we may be certain; and that is, that the tendency of the study of the science of medicine is towards those golden times when war shall cease among all civilized nations.

What! is it to be said that our Profession is inces

santly to be progressing in its inroads upon death, disease, and suffering, whilst, every now and then, nations are to go mad, and undo all our trouble by slaughtering each other wholesale? The thought is madness. Human nature, although, alas! full of contradictions, is always in search of happiness; and as philosophy is fast advancing (although both France and Germany are rather backward in philosophy as yet), we may still hope that our immediate descendants may live to see war looked upon as the greatest of all errors and crimes. Meanwhile, let us again congratulate ourselves on the place assigned to our heroic brethren on the modern field of battle. The cannons and the mitrailleuses directed against their fellow-citizens carefully avoid the camps of the red-cross. Thus, in the midst of war there is peace, and in the midst of enmity, fraternity. All honour to the ambulances of the International Society. Let us all send our mite freely to Paris or Berlin, being certain that in so doing we shall advance the cause of humanity and add to the renown of our sublime profession.

THE LICENSING CORPORATIONS.

A Parliamentary return has just been issued, on the motion of Sir John Gray, which puts us in possession of sundry facts and figures which, probably, we should have had some difficulty in arriving at if we were dependent on the voluntary acts of the Licensing Corporations. This return was moved for by Sir John Gray for the purpose of placing in the hands of members some information preparatory to the introduction of his Medical Bill. It furnishes us with—

"1. The number of each kind of licence, diploma, degree, or certificate granted from 1865 to 1869, inclusive.

"2. The amount of 'the fee' paid for each.

"3. The number of years during which the candidate for each is required to be engaged in studying the Profession, and how many months in attendance at hospital.

"4. The time during which the candidate is required to have been engaged as dresser, clinical clerk, or pupil, stating the dates at which such practical hospital work was declared to be a requisite qualification.

"5. Is the candidate to demonstrate at the bedside of a patient that he has acquired a practical acquaintance with disease, giving the date at which such rule was adopted, and the date since which it has been operative."

The relative proportionate part which each licensing body takes in the qualification of the Profession is the first point in this return which arrests our attention, and it affords us, at the same time, subject of speculation as to the means which some of the Corporations adopt to secure such extensive patronage, and as to why others, who may be said to have no useful *rôle* to fulfil, are allowed to exist at all.

In England, the "College and Hall" so immeasurably out-top the Universities, and even the College of Physicians, that they may almost be said to qualify every medical man.

The College of Surgeons, in the five years, made no less than 1,652 surgeons, and conferred besides nearly 200 fellowships, and 167 licences in midwifery. In other words, it gives 330 licences each year, and only one in ten of its licentiates takes a qualification in midwifery. Its numbers, however, seem to be steadily falling off since 1865, the number of memberships conferred last year being more than one-fourth less than in 1865.

Hand-in hand with the College of Surgeons goes the Apothecaries' Company, which granted last year 275 licences, and, on an average of the five years, 261—a number approaching within about one-third to the total of all the medical practitioners qualified in England.

The "Hall" appears, also, not only to maintain its long-enjoyed prestige, but to improve its position from year to year, for its figures show a steady, if not a very large, increase.

By virtue of the axiom which makes a man respectable because he "keeps a gig," the College of Physicians of London may be said to "keep a gig;" for it occupies, in relation to the College and Hall, what betting men would call a bad third; and it is perfectly evident that the rank and file of the Profession either do not take a medical degree, or they seek it elsewhere than in London.

The five years' average of the College of Physicians shows that it confers annually 70 licences and 18 memberships, and that the demand for its qualification is not improving.

As qualifying bodies the Universities of Oxford and Cambridge may be eliminated altogether from the calculation, for the number of persons who seek the honours of M.D. Oxon, or M.B. Cantab, are utterly insignificant. The largest number of Bachelors of Medicine capped in any one year in Oxford was three; while in Cambridge the total number of medical and surgical degrees conferred did not exceed on an average five.

The University of London has, however, put in a louder claim to being the Medical University, and, in view of the figures before us, its effrontery seems marvellous. If report speaks true, it was in favour of this establishment that the amendments—save the mark—of the Medical Bill were introduced, and it might have been supposed, by the tone of *hauteur* adopted by it, that it exercised some influence in medical education, or was likely to take a leading position amongst licensing bodies. The truth, however, as elicited by this return, places this institution in the same category as South Kensington, as an insatiably expensive job without it possessing the merit of making any return to the country for its cost. The degrees of Bachelor of Medicine and Master in Surgery are the two working qualifications conferred by the University, that of Bachelor of Surgery not being recognised by the Medical Council as a qualification to practise. The University granted last year seventeen Bacalaureates in Medicine, and made one Master in Surgery. In other words, it qualified about one-twenty-fifth part of the aggregate number of doctors qualified in England. Nor does the London University give promise of greater results, which might justify the Government, even in anticipation, in humbling the Profession at its feet. In 1866 it granted twenty-eight working degrees, and every year since the falling off has been steady and decisive.

So far, then, as English qualifying bodies are concerned, the return puts before the Profession a very plain conclusion as to whose hands it is in which Medical Education is placed.

Seven-and-a-half-tenths of all English Licentiates take the licences of the College and Hall; one-tenth are qualified by the College of Physicians; and one-twentieth by the Universities. We shall proceed with our analysis next week.

Notes on Current Topics.

About the War and Wounded.

Who thinks of anything now but this hideous slaughter? Scraps and notes in relation to it seem to absorb the attention of all newspaper readers; and, of course, doctors, on whom devolves the care of the worst sufferers, cannot but be doubly interested.

Disease is likely to be more fatal than the sword if the war be not speedily brought to a close. We believe the Prussians are already suffering severely. As we predicted, the advent of rain instantly had the effect of causing sickness. As the Prussians are unprovided with tents, or other mode of protecting themselves from the inclemency of the weather, unless they can obtain a speedy peace, they will find Providence fighting against big battalions.

It is said that the Germans are alive to the evils of overcrowding, and we can add that French medical authorities are equally well informed. But can overcrowding be helped? Must not every available hospital be overcrowded? When we reflect on the numbers to be attended to, and the small space available, we are as concerned as we are at the impossibility of the surgeons present sufficing for the thousands of our wounded fellow creatures.

Think for a moment of the numbers of the killed and wounded that have been reported already, and it is obvious that medical and surgical aid could not have been bestowed on a tithe of them. The reports, we know, at present are very incorrect; but the history of all recent wars has told the same tale of immense numbers perishing without help. The Crimean of 1854-5, the Italian of 1859, the Danish of 1864, the Bohemian and Italian of 1866, the American war of 1861-1864 all prove that the ordinary medical staff of all armies is utterly unable to cope with the mass of suffering which follows a great battle. At Solferino there were nearly 42,000 killed and wounded. Between May 4th and June 20th, 1864, there were 8,487 killed, and 44,261 wounded in the campaign in America. At Sadowa there were upwards of 20,000 wounded. Three days and three nights passed before the wounded could be collected from the field after this battle. After the battle of Gitschin in the same campaign, wounded men were forty-eight hours without nourishment of any kind. We need not quote the numbers that have figured in the newspapers in this last war. They are fresh in the memory of all—or, at any rate, all know that the mass of maimed men has been most horrible to contemplate.

Some English surgeons have been sent out by the Society for Aiding the Sick and Wounded in War. Their services have been readily accepted, and we need not say they are working hard at their posts. The same Society is sending out medical and surgical necessaries, and it may suit some of our readers to present to them articles of this kind. Surgical instruments and appliances of all kinds will be thankfully accepted for this purpose, and immediately forwarded, as will also chloroform, opium, and the hundreds of things that it is not necessary to specify for professional readers.

M. Michel Chevalier has been writing in the *Revue des Deux Mondes* respecting the sanitary condition of the French Armies. He speaks of the defects noticed in the Crimea, and considers that these defects originated in various ways, all of which have been many times exposed and condemned. The great evil of all is that the Medical Department in France is subject to the "Intendance" Department, and this gives rise to many inconveniences. M. Chevalier condemns this, as well as many other things. He points out, too, how inefficient is the number of surgeons, and tells us that no less than forty-five out of eighty died in the Crimea from the overwork imposed on them.

Have explosive bullets been used? We do not believe in the reports that have been started either as to this or any other infringement of the Geneva Convention. In war time such reports are sure to be spread. Some are pure inventions; others arise from accidental mistakes. We may here quote the result of some experiments that Mr. Adams lately made: 1. An explosive bullet discharged into the head of a horse caused instantaneous death. There was only one report; a little blue smoke curled out of the wound; the bones of the head were shattered; the brain utterly destroyed, presenting merely a disorganised pulp; where the bullet lodged at the back of the head there was a cavity seven inches long, by six inches broad. 2. Another horse was killed by a plain bullet in the head. The bones were not shattered, and the brain was completely uninjured; and, although the animal dropped immediately, the subsequent quivering of the limbs showed that death was not so instantaneous as it had been in the other instance. 3. An explosive bullet was discharged into the thorax of a dead horse. From the wound itself there was no smoke; but, on the chest being cut open, a considerable quantity issued forth. The bullet penetrated and shattered one of the ribs, and lodged in the opposite side, having produced immense laceration of lung tissue. 4. An explosive bullet, when fired against bone, produced widely-extending comminution.

The Volunteer International Ambulances are expensive, but of incalculable value. The complement of each is 27 surgeons and assistants, and 60 "*infirmiers.*" One ambulance can attend to nearly 2,000 wounded, but ought not to be so pressed. From 1,000 to 1,500 is a large number to attend to. The Paris newspapers have subscribed and furnished one.

At Metz we are told that M. Sonard, who organised the Brescia Hospital in the Italian war, has the sole charge of the hospital arrangements.

One of the most important things to help troops to fight well is to feed them well, and yet we hear of the supplies being endangered here, the rations being reduced there, and, in another place, regiments going into a fight with empty stomachs. Troops should never want in this way. In fact, they should be well fed and exercised, so as to keep them in good condition in time of peace, and it may be worth while to take this opportunity of directing attention to the diet of our own Army. We fear it is not to be denied that both the quantity and quality of the British soldiers' diet are defective. This subject should be considered by the authorities.

But, in regard to our own immediate help to the wounded, diet, too, is of great importance. If compelled to choose between unlimited surgical appliances and an unlimited supply of good food for the wounded, we should be inclined to trust to the latter. Here, then, is a hint for those helping: Concentrated foods of all kinds, con-

densed milk, Liebig's extract of meat, and such like articles may really be of greater use than instruments, which are only needed to supply the surgeons present. In the absence of professional men, such foods and medical comforts need not lie idle as bistouries, amputation knives and saws do.

These, too, may save from the diseases which may be expected to ravage the camps. Such close agglomeration of human beings always leads to sickness, for which, and as a preventative of which, abundant food and medical comforts are urgently needed. Abundant food, in a dietary of great variety, to guard against scurvy, fevers, and other outbreaks, and to succour the injured and those falling ill, ought to be provided for in every army; but, alas, how often do privations exist!

Dr. Thudichum strongly advises the sending out of condensed nitrous oxide. Is it certain that the military surgeons of the Continent are accustomed to use this agent or possess the apparatus?

There are nearly 2,000 Parisian medical men and students ready to serve, but who have not yet been employed. Red tape seems worse in France than England, and even in this crisis is not swept away.

The Germans have tried a condensed diet in the form of a kind of pease pudding, in which smoked meat, chopped up small, has been mixed. A lump of this forms a complete meal of animal and vegetable food. It is said to be good cold, but can be improved by boiling when the soldier has the opportunity of getting water and fire.

It is no easy thing to imagine what 20,000 wounded means. The words are easily pronounced, but the idea can scarcely be grasped. One thing it means is, that many of the sufferers are left untended on the field. A correspondent gives us a heart-rending description of a number of these unhappy sufferers, who had not been removed on the third day after the battle in which they fell before Metz. The number of surgeons is utterly inadequate for modern warfare.

Why will not our Government send out a number of military surgeons? By the Convention of Geneva they would be accepted. They would gain invaluable experience in case we should be involved in war. They would be of great benefit to the miserable sufferers. There are plenty who would rejoice to go instead of eating their hearts out at home. If there is something for them to do, throw that duty on the medical staff of the Militia or the Volunteers, and so give those surgeons some practical experience.

So beyond all calculation have been the numbers of the wounded, that many German towns have heartily responded to an appeal to the inhabitants to take them into their own homes. This is an excellent plan. Distribute as widely as possible all the wounded—and German towns can easily receive many. But unhappy France! How can such comforts be provided in an invaded country? In this respect our sympathy for the French wounded should be redoubled. With requisitions to feed the enemy, how can the poor people tend the sick and wounded?

As we go to press we hear that pyæmia and fever are raging in the citadel, where some 15,000 or 20,000 wounded lie. It may be that before this reaches our readers' eyes, it can be of little consequence as to the course of the war; but it is of great importance as a medical event, which we predicted would occur.

Showing Children London.

We had hoped the unpardonable and dangerous practice of lifting children by the chin and occiput in order to show them, as it is said, London, was a cruelty practised by the unthinking and ignorant-minded of a past generation. About a year ago there was recorded, as well as we can recollect, a fatal case, wherein a nursery maid lifted her charge off the ground in order to show it London. The child died immediately, and a *post-mortem* examination revealed a rupture of the transverse ligment and a falling forward of the odontoid process upon the spinal cord. We were horrified a few days ago, as we walked through a fashionable park, observing a man lift several children one after the other by the chin and occiput, and swinging them from side to side, whilst he repeated a portion of a rhyme which we think Dean Swift never meant for so dangerous a practice—

> Here we go up, up, up;
> And here we go down, down, downie;
> And here we go backwards and forwards,
> And up to London townie.

Upon repeating the third line the child got a lateral swing, and the last line had it suspended "high in air." This is just the most likely way to dislocate the *axis* from the *atlas*. We wonder when people ever will have common sense. It is too late, when death occurs, to remedy an existing evil practised through ignorance of the consequence. We think, then, wherever children congregate in numbers, the policeman should have his eyes open to head-swinging, and make a few examples in the police-court. Fine, or imprisonment, will most likely destroy, by the publicity given to the punishment in the daily papers, a dangerous and absurd practice.

A new Sanatorium for the Winter.

Our readers will remember that last spring we announced a project for establishing a Sanatorium at Cairo under the control of Mrs. James Appleton, of Portsdown House, Clifton Gardens, W. We have now the pleasure of stating that all arrangements have been completed, and that Mrs. Appleton intends to leave London the first week in October, and would be willing to take charge of invalids who may propose to spend some time in the beautiful climate of Egypt. In the midst of the uncertainty respecting Continental health resorts, and considering Mrs. Appleton's experience, we can freely add our opinion to that of some of the most eminent members of our Profession, that invalids can scarcely do better than avail themselves of such an opportunity.

The Coal-miner's Spine.

The condition of the spine of the collier who works in damp mines has not, we believe, been written upon. We had an opportunity lately of watching a number of coal-miners going to and returning from the "Pit." We remarked the peculiar gait of a number of these men, and directed the attention of a local practitioner to the circumstance, but this gentleman was so accustomed to their appearance that he overlooked what appeared a peculiarity and an

abnormal state of things to us. They walk with the head and shoulders bent forward, and the lumbar and sacral regions projecting greatly behind. The legs seem stiff as if there were little movement about the hip joints, with a superfluous amount of genuflexion.

We had a few of these colliers undressed and examined. We found that in all those who walked as we now describe, there was antero-posterior curvature of the dorsal spines; that the man was unable to stand erect, and that there was a very considerable amount of stiffness about the hip joints. We were unable to detect any tenderness or learn from the collier that he suffered from pain or actual inconvenience. They all invariably ascribed the distorted spine to being sent to work in a damp pit at too early an age; the deformity was slow and progressive, yet one youth of three-and-twenty years had the gait and appearance of a man of fifty. We gathered from not a few that lying on the back, for the purpose of striking the "Bind" with their pick, on a damp surface, produced rheumatism which terminated in the stiffness, and eventually in the deformity. The curvature is irremediable, for we saw a man of fifty who had not worked as a miner for many years, yet he retained the hollow back with a well-marked concavity directed forwards.

We recommended a few young colliers to wear washed leather bands around the back as a preventative, and we shall return to the subject when the result is recorded to us.

Hair Restorers.

From the analyses of Professor Chandler, it appears that lead is the universal ingredient of these quack preparations. In fifteen different kinds examined he found this metal in all, the lowest quantity being one-ninth of a grain, the highest sixteen grains in the ounce.

In one lotion for the skin he discovered corrosive sublimate!

The fashionable enamels he found to consist of carbonate of lime, oxide of zinc, or carbonate of lead.

Infant Mortality.

The Quarterly Returns of the Registrar-General show that taking an average of the Kingdom the deaths of infants and elderly persons may be regarded as the same; but that, in considering the mortality separately, there is great local variation, and that in some places the infantile death rate is excessive. In Staffordshire and Lancashire the proportion is great, whilst in Devonshire there are not one half the children die compared with those over sixty years of age. Infants appear to die quickly in Bradford, Liverpool, Manchester, Leeds and Bristol. The county of Nottingham has long had an evil reputation respecting its infantile mortality; this quarter we find the number of deaths compared between young children and elderly persons is about equal, but we have made inquiry into the cause of a previous increased infantile mortality, and we learn the cause is chiefly dependent on the nature of the employment of the people, and to the neglect of the children. In Sutton-in-Ashfield, for the quarter ending in June, there were 125 births and 112 deaths. Of the latter the greater number consisted of children under a year old. A correspondent living in the district tells us that nearly all the residents have large families; some women have borne twenty children, and every fresh addition, particularly at the present when work is scarce for the stocking knitter, is looked upon as an intrusion, and the parents are only too thankful if the child "goes back." We believe the children are generally born healthy, and free from disease—syphilis being rare, owing to the early marriages and the mutual arrangement married couples enter into if dissatisfied with each other as to separating and taking a fresh spouse—but after birth they receive little care or attention. If irritable, or suffering from colic, they are speedily dosed with Godfrey's cordial, or some other anodyne, as the mother generally is forced to wind the cotton on bobbins in order to keep the husband employed in the frame, so that there is little nursing, little maternal care, and no anxiety manifested whether the child lives or dies; accordingly, the infant mortality of Nottinghamshire is truly great. We understand in the coal mining districts the mortality is not near so excessive in proportion as in the frame-work knitters' towns and villages. If epidemic disease, as measles, scarlatina, or typhoid fever, affect them, what from want of proper nursing, and the great defect which exists in sanitary arrangements, the number of deaths are out of all proportion. It is difficult to recommend a remedy for this infant mortality; that it is due to carelessness on the part of the parents, and to the want of proper precautions being adopted by the authorities, there is no disputing. It is out of the question trying to teach the people the value they should set upon the lives of their offspring; but, we believe, the authorities should put their *veto* upon the reckless and indiscriminate sale of syrups containing opiates, that the pennyworths of Godfrey's cordial should be stopped, and that Local Boards of Health should be formed, under the Towns Improvement Act, to look after, and if need be improve, the sanitary condition of the locality; that in all cases of suspicious death the coroner should direct a *post-mortem* examination to be made, and should not be satisfied with the statements of interested relations who in many instances, our correspondent tells us, overdose their children. No medical evidence is sought by the coroner, and some absurd verdict returned by a jury at his dictation.

This is a miserable state of things, and readily enough teaches a surprised Registrar-General why infant mortality is so excessive in certain localities.

"The Love that Kills."

Scarcely a week passes that we do not observe in the police intelligence column of the daily newspapers, the report of some poor deluded woman brought before the presiding magistrate, who attempted self-destruction because of being *enceinte* to some wretch, who deserts as soon as he betrays; or who is driven to desperation in the agony of her grief, and in the deep force of her love, because of the duplicity and villainy of the tempter. Foiled in the extreme step of suicide, justice satisfies itself with a week's remand of the offender, with the advice of the prison chaplain during the interval of the weary week, and an acquittal with a caution as to the future. Should the self-destroyer succeed in the act, society is satisfied with a coroner's inquest, and a verdict of temporary insanity; but society never troubles itself further with the poor fallen sister, who, in the anguish and bitterness of a self-convicted mind, tried to rid herself of the world's callousness and hard-heartedness, because of her own weakness and another's guilt, and she just steps from the dock to face the

world anew with a fresh stain upon a character—the loss of which drove her to the act she stood charged with.

We don't refer to the depraved woman whose profession is prostitution, and who either from advancing years, increasing poverty, chronic alcoholism, or incipient *delirium tremens*, attempts suicide ; we confine our remarks to the first fallen, whose innocence in their confidence of some monster in human form, deprives them of the world's good name, and robs them for ever of that which is most dear to woman. No matter how often a man may stray from the bidden track, the world overlooks his folly, and he quickly recovers his position ; but, when the chaste spirit of a virtuous woman is once tarnished, and her fair fame is defiled, society, in their civilization, close their eyes upon the degraded one, and shudder at her presence. This it is to which we object, for we argue if a woman falls once, and, by conduct, demonstrates how keenly the blow is felt, and how acutely she suffers mentally, that a chance should be held out to her for reformation. What becomes, we ask, of all those young women driven mad in their despair, who weekly come before one of the divisional magistrates ? Do they return to their homes to become useful members of society ? Do their relations and friends receive them as before ? We fear not. We believe, and our hospital experience teaches us the fact, that they are driven to prostitution for the sake of an existence. They dread meeting their relatives, and they adopt the only course open to them, for, without reference as to character, they are deprived of obtaining honest employment.

It is truly deplorable in the syphilitic wards of our large hospitals, in being made confessors of woman's weakness, to be told tales even from sinning lips that would make even the hardest hearted shudder, or the greatest worldling weep over the wreck which disease and debauchery have worked, and from which some timely succour in some temporary haven might have rescued them for ever, had it been offered at the first downfall, when the modesty and inward horror depending on a ruined character developed itself. We think we are the first to herald the good tidings that an active and competent member of the House of Commons will, in the next Session of Parliament, direct the attention of the State to this grievance, and will in addition ask for a measure that will have for its object the punishment of the seducer in a summary manner. Our only wonder is, why England has remained in apathy and apparently cold indifference so long, over so serious a social grievance, but if the Government will support such Asylums, and give the erring woman in her first backsliding from strict propriety a chance of reforming and of regaining a position lost, and wiping off the tarnish upon her moral character, it will truly be a most praiseworthy action, and no body of men will know how to appreciate it, after the poor victims themselves, better than the members of the Medical Profession.

Private Lunatic Asylums.

In a recent tour along the borders of Wales, we visited the Asylum at Church Stretton, the proprietor of which, Mr. Hyslop, offered us every facility to acquaint ourselves with the medical and domestic arrangements. We wandered about the establishment and grounds without let or hindrance, entered into conversation indiscriminately with the patients, and were pleased to see such order and contentment reign. A greater testimony to the character and worth of the proprietor of this asylum could not be found, than that more than one patient, when discharged cured, had obtained permission to still reside in the house as private boarders. The following particulars gathered at the visit referred to will, perhaps, interest some of our readers : Patients are accommodated, and receive the comforts of a first-class home, at terms varying from a guinea a week upwards. The Home Park is over 100 acres in extent, and the walks and drives by which it is surrounded are amongst the most romantic and picturesque scenery in the kingdom. The out-door amusements, such as cricket and gardening, are much appreciated in fine weather, whilst equal regard is paid to indoor recreation in the shape of billiards, music, &c. ; and for the more wealthy, additional luxuries are provided in saddle-horse and carriage exercise. To the physiologist, an asylum of this class, which necessarily contains the better class patients, affords an illimitable scope for study. The farmer patient, ever ready with advice as to the management of the homestead, which, fortunately for the cattle, could not always be adopted ; the phrenetic barrister insisting upon —what those piping worthies never do—pleading your cause gratis. We were, ourselves, generously offered the next presentation to a Professorship at Oxford University, value half a million, by a *passed* Oxonian ; and a still more valuable document was placed in the hand of the proprietor, at the Asylum Board, which consisted of a strip—the margin of a newspaper—whereon was written, pay to the order of W. Hyslop, Esq., the sum of £800,000 ; whilst another peripatetic, formerly one of the most eloquent of town councilmen in a neighbouring city, displayed his bent in a phylactery upon which was written "mottled soap," and about which decidedly useful article he was wont to indulge in a peroration of no mean order. For the last twenty years, private asylums have been open to the inspection of the public, and every means adopted to remove those impressions which such novels as *Valentine Vox* had not unnaturally impressed them with ; and now that Psychology has become an advanced and defined science, it is really pitiable that such superlative twaddle should still be preached by one or two contemporaries, who speak of "rib-breaking" and "bone-crushing," as if asylums, public and private, were nothing better than improvised mills to reduce those osseous portions of the human economy to a state analogous to the brains of the writers. With reference to certain prolific causes of insanity, we will give Mr. Hyslop's words, feeling that the opinion of a gentleman of such extensive practical experience and acute perception should carry its own weight. He said "there is no doubt that among the chief causes, are, nervous diseases and quackery ;" and that in the pockets of many patients he finds on entering, one or more of the villanous pamphlets of the quack scoundrels who infest every large town, sowing destruction broadcast through every village and hamlet. Can nothing be done with these ? Mr. Hyslop further thinks that the indiscriminate mixing of the idiotic and insane with the general community is a fruitful source of chronic idiotcy, and the public should be taught that asylums are as essential for the treatment of *mental* diseases, as are hospitals for *bodily* ailments. Referring to public asylums he maintains with some show of reason that no building should contain more than 300 or 400, that an acre of land for tillage and other purposes should be secured for every four patients, and that the medical superintendent should be monarchical. Managers should

be appointed over the male departments, as matrons are over the female, being responsible for the conduct of the attendants, &c. At present, the medical superintendent is overloaded with the internal economy, and has not, therefore, the time to devote to his more important professional duties and requirements in an establishment containing five or six hundred patients. We were glad to find throughout such excellent management here ; and, in mentioning, as an illustration, the one we have just visited, we need only add that it is not an exception to the rule, and that plenty of others would be found had we more time and space to devote to the inquiry. The establishment we have spoken of is for gentlemen only, Dr. Clement, M.P. for Shrewsbury, being the consulting physician, and Dr. McClintock, the medical attendant ; but there is another similarly conducted for ladies about a mile distant, under the proprietary of Mrs. Bakewell, widow of the late Dr. Bakewell, so that the little town of Church Stretton can boast of two of the best private asylums in Great Britain.

Official Incompetency in Matters Pharmaceutical.

The evidence given before the Select Committee on the Abyssinian Expedition discloses the incredible fact that the loss on the sale of medicines ordered for that undertaking was £35,829.

In any other country where official incompetency is less glaring, and commercial corruption less flagrant, so scandalous a transaction would be marked by some decisive action on the part of the Government. Let our readers picture to themselves the rottenness of our administrative departments when an over-supply faintly represented by a per-centage loss of nearly £40,000 can pass the observation of responsible controllers.

Professor Huxley will give the Address at the British Association next month.

Scarlet Fever is increasing in London.

Mr. B. Carter has been appointed Ophthalmic Surgeon to St. George's Hospital.

Baron Diergandt has given £10,000 to the German Hospital, London.

The Mayor of Aberystwith, whilst preaching on Sunday last at a dissenting chapel of which he was deacon, was attacked severely with paralysis, and fell almost lifeless among his congregation.

By a new Act of Parliament, the Poor-law Board may define cases in which the guardians of a parish may pay the expense of a pauper's conveyance.

The Director-General of the Medical Department of the Navy, Dr. Armstrong, R.N., has concluded his official inspection of the naval medical establishments at Plymouth.

The new law of life assurance is now in force, and we trust will be found of some protection ; at any rate, it will enable proposing assurers to ascertain some of the facts of the company's finance.

M. Husson, the Director-General of Public Assistance for the Hospitals at Paris, has obtained from the War Minister an exemption of the Hospital Students from military duty.

M. Wurtz, Dean of the Faculty of Medicine, has put forth a statement that the students who are inscribed in the registry of the Val-de-Grâce, shall be retained in Paris, and in the localities where they may now be, and will not be required to report themselves at the military depots.

The Poor-law Board have not approved the proposal of the St. Pancras Guardians to require their Medical Officers to devote all their time to the poor. The only objection to such a move is the vested interest of men now in practice. Could not this plan be gradually brought into operation ?

We hear that the general health of Lady Mordaunt has lately improved, but that her mental state is such that it is necessary for her to remain under medical care. She is in a first-class and most comfortable private asylum near London.

The *Peuple Francais* makes the following statement, which may be worth much or nothing :—" We are informed from Soulz of a violation of the Convention of Geneva in the case of Army Surgeons acting under Marshal MacMahon. Several Medical Officers have been detained for the last eight days, and—what we should not have believed unless we had personal knowledge of its truth—their horses, baggage, money, and clothes have been taken from them ; and, not content with these indignities, the Prussian officers would not give them during their imprisonment either food or lodging. Many of them were obliged to lie on the ground, and had nothing to eat for several days but potatoes found in the fields."

M. Dorvault, Director of the Central Pharmaceutical Establishment of France, has presented to the Society for the Succour of the Wounded 100 kilogrammes of quinine, 500 litres of quinine wine, and material for 10,000 litres of hygiene drink. In addition, he has put at the disposal of the administration at St. Denis, five chambers with beds for wounded officers, buildings for the accommodation of ambulances for 200 wounded men, stables for horses, with every necessary medicine, and a fire brigade of ten men.

It has been stated, upon what we must reluctantly consider good authority, that a successor has actually been appointed to the late Military Commandant of the Royal Victoria Hospital at Netley. That such a functionary is as much out of place in an establishment, the sole purpose of which is the relief and cure of the sick, as a medical man would be at the head of a regiment, has so often been remarked, that we now almost hesitate in printing the

self-evident fact. We have observed, with considerable satisfaction, the resolution displayed by the Admiralty in abolishing the position of Captain Superintendent of Haslar Hospital, at the same time that we congratulate Inspector-General Salmon upon the success and efficiency with which, under his sole rule, the entire administration of the establishment is conducted, including matters of professional detail, of finance, and discipline; nor have we ever heard it asserted that the absence of the late Governor of Netley has been missed in an official sense, whatever it may be in a social. There is not a doubt that the Inspector-General there could conduct the whole duties of administration as easily and well as Dr. Salmon does at Haslar, at the same time that a considerable money-saving would be effected to the public, and a good deal of irritation saved to officers more immediately concerned.

The time has more than arrived when each department of the public service ought to be held responsible for what directly concerns it, and for no more; military officers should be so for those of a military nature; medical officers for all that bears upon the treatment, accommodation, and general management of the sick; but of all places, hospitals are surely the very last in which military pomp and circumstance are in any way appropriate. We are aware that it is in contemplation to abolish double government in military hospitals, and to throw the entire management upon the medical department. This is as it should be; and it is to be devoutly wished, considering the present aspect of public affairs, that such a change may not be long delayed, at a time when all preparations for probable emergencies ought to be completed. Perhaps, therefore, the military authorities may yet be induced to leave well alone as regards Netley—taking in this an example of what has been done, with such excellent results, at Haslar. May we point to some of the results of military administration in the French Army as quite recently described, and ask if such a system should be any longer copied in ours? It is thus summed up in the *Pall Mall Gazette* of 23rd August:—"But the beaurocratic obstacles have been too great, and the sufferings of the wounded on the French side have been frightfully aggravated by official incompetence." So much for their system of military *intendance*.

SCOTLAND.

GLASGOW.

The trustees of Anderson's University have elected Dr. J. E. Thorpe, Owen's College, Manchester, to the Chair of Chemistry, vacant by the death of Dr. Penny. The other candidates were Dr. J. Campbell Brown, Liverpool; Mr. Tatlock, Glasgow; and Dr. John Clark, Glasgow.

EDINBURGH.

It is stated that the University authorities contemplate purchasing the buildings and grounds of the present Royal Infirmary. The price mentioned is about £20,000. The foundation stone of the new Infirmary is expected to be laid in October next, when it is hoped the Prince of Wales will preside.

A general Poor-law order has been issued to the effect that appointments of Medical Officers after Sept. 29 next will be permanent.

Hospital Reports.

Remarkable Case of Alopecia, the Result of Cerebral Injury.

By R. Cooper Todd, A.B., Staff-Surgeon.

Alopecia, partial and complete, is often the result of special dyscrasiæ, or zymotic diseases. It has followed parturition, and in fact any influence producing cachexia. It is, however, generally regarded as a manifestation of syphilitic infection, and some have blamed the exhibition of mercury for the baldness.

In such cases, however the loss of hair is mostly partial, and it is confined to the scalp. It is also generally slowly progressive, extending over a few weeks, or even months; and the patients are apt to recover as the cachectic state passes away.

In the case about to be recorded, however, the loss of hair was general, and took place, when it began, at once. The patient was a strong, healthy, hirsute man in the prime of life, and free from any scrofulous or syphilitic taint. The alopecia came on, it is true, some time after the cerebral injury, and after the exhibition of both mercury and the bromide of potassium, yet it can scarcely be doubted that the history of the case, particularly when compared with that of another similar one, points to some nervous influence as the cause of baldness.

It may be well to mention that the original cerebral injury was treated on the expectant principle, nourishment and even stimulants being cautiously administered. The exhibition of mercury was proposed by that distinguished practitioner, the late Dr. Hutton, whose valuable aid I had solicited, but the medicine was not administered, in deference to my opposition; and it is curious to relate that the very first serious symptoms in the case followed the action of two mercurial purgative pills, taken without advice by the patient himself.

It is thought that the unique character of the case justifies the hope that it is worthy of a place among the recorded cases in the Army Medical Report, although the case *per se* has already appeared in the pages of the "Lancet."

In the summer of 1863 I was called to see a gentleman, aged about forty-five, at an hotel in Bray, Ireland, who had been thrown from the side of an Irish car upon his head, and received a partial concussion of the brain. Immediately after the accident he was quite master of himself, and able to continue his journey until he reached the hotel, which was about four miles from the site of the accident. When I saw him he was slightly confused in mind, but perfectly able to answer questions, and conscious of the passing events. By my advice he remained that night in the hotel; but the next morning, before I had time to visit him, he had left the hotel and returned to his home in Dublin, a distance of quite twelve miles, which he accomplished by rail and by cabs. In the course of the following day, and for a few days after, some alarming symptoms supervened. Hemiplegic convulsions of an epileptiform character came on, accompanied by total unconsciousness; but the fits were of short duration, and in the interim the patient was collected. There was, however, present at times a peculiar kind of delirium, like that common in some low fevers. The patient rose from bed, seemed anxious to hide away and lock up in his chest of drawers trifling articles, such as a grape or two, and on one occasion he tried hard to throw himself out of his window; but at the same time, when addressed, he was quite amenable to government, and recognized those about him. In a short time he quite recovered, and in less than six weeks, I think, after the accident, managed successfully some very important private business.

However, in the course of time, he suffered, as he stated himself to me afterwards, from occasional headaches, and he sought medical advice, I think, in Scotland. He then

underwent a course of mercury, and subsequently took daily, for about twelve months as I understood him to say, thirty grains of the bromide of potassium, when he found that one morning, on proceeding to shave, he had no beard to cut; and subsequently and rapidly all his hair fell out, not only from his head and face, but from his chest and body, and up to this time he had been, as I have said, a very hirsute man.

This peculiar result of the accident was brought to my notice only the other day (1869) by the gentleman himself. He was then in excellent health, but perfectly free from any trace of hair. He stated that his taste and smell were not quite so good as they used to be, but that in every other respect he was quite well and hearty, and that he had never had any approach to any epileptiform seizure since the first attack.

At first I was very much disposed to regard the alopecia as the result of the action of the bromide of potassium. This idea was strengthened by considering the effect which the continued use of the iodide has been known to have upon the testes in males and upon the breasts in females. I gave up this idea, however, on reading the report of a case, similar at least as far as the loss of hair goes, alluded to in Holmes's "System of Surgery," article "Accidents from Lightning," which was pointed out to me by my friend, Dr. H. Massey. In both cases the baldness followed nervous shock. In the one mentioned by Mr. Holmes, the depilation began the day after the accident, which was a lightning stroke. The patient was a naval captain, and during a thunderstorm he was knocked down by lightning, and the very next day the hair fell off from all his body. In the following year the finger-nails (wrongly printed in the "Lancet" "toe-nails") "scaled away," those of the toes experiencing no visible change.

As it is quite clear that the alopecia was not the effect of treatment in the case recorded in Mr. Holmes's "Surgery," so I think it may be fairly inferred that the baldness in the case of my friend resulted from cerebral injury, and not from the subsequent treatment.

Correspondence.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

[LETTER FROM DR. C. R. DRYSDALE.]

Sir,—As this is the usual time for taking an annual holiday, I have thought it might be interesting and instructive to visit the country of our neighbours and allies, not only in the day of their pride, but also whilst they are suffering so terribly from that curse of the race, war. We heard, indeed, rumours that, because Paris was *en état de siège*, we should not be allowed to enter the city without passports, and as I had not provided myself with one of these somewhat antiquated papers, I began to think I should be condemned to hear about the war doings in some *bain de Mêr*, such as Etretat or Trouville, both of which I visited *en route* for Paris. However, on arriving at the fortifications of the town by the gate which leads to Versailles, no objection was made to the entrance of any of the passengers in the carriage which I occupied, and we passed through, having, however, to make a détour, because the road was being obliterated in order to construct a drawbridge, instead of the ordinary route. But when we passed through the Place de la Concorde, it was still more evident that we were in a city suffering under the suspense and agony of war times. There had been a disturbance the day before, and the troops had charged the crowds in the Place; while even on this, the day after, groups were scattered over its vast extent, conversing in an animated manner about the advisability of getting rid of the Emperor and family, and proclaiming a Republic, to avenge the defeats of the previous days.

Were I member of a profession accustomed only to cheerful sights, I should, indeed, have remained out of this city just now. Paris is plunged in the deepest sorrow. No music, no amusements are cared for. Everyone reads the journals from morning till night; men and women, too, rich and poor. Everywhere you hear that such an one has lost his son, or her husband, or brother, or dear friend in those accursed combats of Wissembourg, &c. The hearts of our medical brethren, too, are sad. They seem, in the exercise of their profession as hospital physicians and surgeons, to ask themselves, "What use are our feeble efforts, towards saving a few damaged lives, in comparison with the atrocious losses inflicted in an hour or two by the deadly engines of modern warfare on so many thousands?" The only redeeming feature of the moment in my eyes is the *Society of Succour to the Wounded Soldiers*, which holds its committee meetings in one of the wings of the Palais de l'Industrie. The morning after my arrival I hastened to visit this admirable bud of modern philanthropy, and had the good fortune to be shown over the whole of the departments by a kind Frenchman, a professional brother who had served in America during the war and on the same service. In one of the rooms sat the amiable and eminent senator, Nélaton, who is the director of this, as well, I believe, as of the ambulances of the army.

The ambulances of the International Society are destined to assist those of the army, not to do away with the necessity for the latter. When I visited the Palace of Industry, there was a notice posted up to the effect that the medical staff being complete, no further medical volunteers could be accepted. This speaks volumes, does it not? for the generous intrepidity of our brethren in the profession in France. Everyone knows that the medical service of the ambulances is fraught with danger to the lives of those following it. Besides the danger of being shot by the enemy's bullets, which is by no means small, there are to be taken into account the dangers of pyæmia and of the diseases of armies, which so constantly carry off large numbers of the medical men and attendants on these ambulances in times of battle. Two die from disease to one from war. I had hoped to see M. Lefort, in order to converse with him on the Contagious Diseases Acts and other matters I had considerable interest in, and on which he is a great authority; but he, too, was no longer at the Hôpital Cochin, having set off a week before my arrival in charge of one of the ambulances. And on visiting the Hôpital du Midi, I found that the surgeon, M. Liégois, had just departed on the honourable errand of solacing the miseries of this most terrific of all wars.

From different causes, I find that there are very few of the sick and wounded in any of the Parisian hospitals as yet. There was said yesterday to be only some twenty or thirty wounded men in the Val-de-Grâce Hospital, and a few more in the hospital for old age in the Rue des Recollets. But if the 15th of August or thereabouts is to be the day of a great battle, as all seem to say it is likely to be, then there will be beds in all the hospitals for wounded and sick both here and I have no doubt in most of the provincial hospitals. Consequently, in one or two of the hospitals I have visited, the beds were being cleared out, and the patients receiving their exeats in order to prepare for such a dreadful event.

For instance, at the Hôpital du Midi yesterday, M. Mauriac, one of the physicians, was told that 80 of the 300 beds were vacant, and that probably these will be filled in a few days by wounded soldiers. And the same is taking place in most of the other hospitals. There are no students at the Midi at present, and no one to write out these interminable hospital papers but the doctors and patients themselves. I shrewdly suspect that several of the patients in hospitals are glad enough to shelter themselves there, in place of running off to what seems almost certain death in the course of one or two days, and could not help the melancholy reflection crossing my mind when M. Mauriac signed a certificate of ill-health and incapacity for a poor fellow suffering from the anæmia caused by an attack of universal and obstinate syphilitic eruption, that he was lucky to have even this sad disease at such a fearful moment as this, instead of "mourant pour la patrie."

To persons possessed of greater love for the ridiculous than myself, it might have been laughable to see how the Parisians have passed from the state of absolute certainty of succeeding in this war into a condition verging on despair. At first, the journals spoke very contemptuously of the Prussians, and confidently of the superiority of the French in every respect to their neighbours. All kinds of jokes were heard about the love of that nation for beer, tobacco, and ham; and their coarseness and vulgarity were commented upon with considerable freedom. Among the attacks made upon the nation of

Prussia was one contained in a paper called the *Paris-Journal*, which, I must confess, I think nearly hits the mark; at least, I ask any of our German friends whether it is not partly true:—"Like all that is born of damp, the German race spawns rapidly (pullule). A woman who has only four children is accused of sterility. Germany infests the whole world. At London the Prussians have invaded the city. We find them everywhere: merchants at Bordeaux, carpenters or sweepers at Paris, &c. In the United States they will form the majority of the future; and the son of Bismarck will probably desire to annex North America to the German Vaterland." These rapidly-breeding and grasping tendencies of the Germans are certainly the weak point of that clever nation; and I must say, in passing, that able men, as most of the Prussians are, with whom I have lately conversed—there is a deplorable ignorance among even the best men of the German nation—of the most important of all the sciences, *i.e.*, political economy and social science.

As a contrast to the spawning habits of the Germans, I may mention that a Parisian lady told me yesterday that, among her acquaintances in Paris, very few families had more than *one* or *two* children. No wonder that such prudent persons look with disgust on the emigrating and grasping tastes of the Prussians. In the words of Talleyrand they exclaim "Ces pères de famille sont capable de tout!" French people, you know, do not emigrate, but can live at home, and are not forced to overcrowd the already over-stocked labour markets of England and elsewhere like the *pullulating* Prussian. In future, there will doubtless be a strong sentiment against all nations which, like the Germans, tend by their rapid breeding to lower our wages. While I have the pen in my hand I should like to avail myself of the well-known impartiality of your editorship to reply to a few of the observations contained in a letter from Dr. Waring-Curran, a gentleman from whom I have learnt a good deal and hope to learn more. Dr. W. Curran is opposed to one of my remedies for prostitution,—viz., greater facility of divorce. My argument for this greater facility is that my experience among prostitutes as patients—pretty extensive—has shown me that their trade is very largely patronised by married men who have married from mercenary motives, or whose partners are not *par amour*. And I hear from Mr. Conway, a distinguished American literary man in London, that since the establishment of facility of divorce in Indiana, U. S., there has been hardly any prostitution in that State, and that comparatively few persons avail themselves of the six months' notice for incompatibility granted by the laws. Dr. W. Curran chivalrously defends the Catholic clergy of his native country and their dogmas. For my part, I have a sincere respect for all churches, and only question those parts of their moral codes which oppose my experience as a medical man. There are two points in which I quite disagree with our Catholic brethren of the church, and I have often argued with clergymen of that church in France that they ought to change them. The first point is that the Catholic clergy make it a mortal sin, "un peché mortel" to restrain the numbers of a family by any means save that of abstinence. I think that this is quite a silly doctrine, and liable to alienate most men and women from the confessional. The second dogma I combat in the Catholic church is that of irrevocable marriage, as I see constantly that this leads to crime of all kinds, to prostitution, and venereal disease. Lastly, I am just as much opposed to the celibacy of priests as to that of soldiers. Both soldiers and celibate priests are liable to fall into habits of masturbation, or, as my lady friends in Paris assert, the latter class of men constantly use the confessional to gain the persons of married women. I trust Dr. Curran will find that some of my arguments have some weight.

I see a letter in the MEDICAL PRESS AND CIRCULAR from Mr. Haughton on the question of the habitual use of alcoholic fluids. When I mention that I had the fortune to write a few lines on this subject in your columns under the heading, "By a Physician," on the 6th July, which that gentleman refers to with praise, he will see that I am on the side of the anti-alcoholists, and in favour of the habitual abstention from all but simple drinks. I believe that the best chance for longevity resides in simple tastes, and, in short, that the hydropathic theory is not a bad one; only, I protest with my whole soul against Maine Liquor Laws of any description. We have, I am sure, quite too many interferences with our individual liberty in English-speaking countries without adding to them, as Professor Newman and others seem to desire so ardently, the suppression of all trade in wine and spirits. Persuade and convince the world that an innocent and simple existence, free from the false pleasures given by alcohol and tobacco, is the happiest in the long run, and I, for my part, will do my best to help you, and to advance that cause which I believe to be the true and the scientific one. But the moment that anti-alcoholists begin to wish to have recourse to the magistrate, to coerce their fellow-men, or prevent them from doing what they please with their own health, I range myself on the other side, and am their determined foe.

I think it an immense pity that able and energetic men like Dr. Anstie and others should be on the side of the alcoholists, because the giving up of smoking and drinking, a difficult matter at any time to uncultivated persons, is rendered almost impossible so long as we have such clever journals as the *Practitioner* recommending a person in health to take a bottle of Bordeaux wine daily. For my part, I see too many diseases caused by alcohol annually not to be persuaded that it is one of the most dangerous articles of diet; and I also may remark that I have seen too many instances of longevity and perfect health in persons who abstain from it not to feel sure that a bottle of Bordeaux wine daily is anything but a necessary of existence.

I hope, before leaving this, at present, sad but ever charming and beautiful city, to send you a few more notes on hospitals; but this letter is already absurdly long.

Yours faithfully,

CHARLES R. DRYSDALE, M.D.,
M.R.C.P.L., F.R.C.S.E.

Paris, August 14, 1870.

An Incredible Case.

A VERY remarkable case is recorded by Dr. Edward Cass, of Dresden, Ohio, in the *Medical and Surgical Reporter*—remarkable in its phenomena, still more remarkable in its treatment, and most remarkable in its sequel. The patient first discovered at about the age of sixteen "a whitish, watery discharge" escaping from his urethra one day while at work at his trade (shoe making). This discharge occurring periodically every day, he applied for medical aid and took to reading medical books himself. All treatment proved futile until, at the age of thirty-two, he came under the care of Dr. Cass, "much emaciated, an indescribable restlessness haunted him, fluid semen discharging once, twice, or three times during sleep," He denied having ever practised masturbation, "never had erections in his life, nor did the ejaculation of semen produce the least sensation approaching organism."

The treatment proposed, and agreed to by the patient, was castration, which operation was performed by Dr. Cass on the following day. The day after the operation we are told that "about four o'clock, while in a dreamy state, the 'muscles went through the motion'—as by habit, a small discharge following;" the same thing recurring twenty-four hours afterwards. But the most extraordinary part of the story still remains to be told. A year after his emasculation, the patient announced to his physician that he was "troubled" with vigorous erections and sexual desire (things which he had never experienced before), and that he contemplated matrimony. This intention he actually carried out, and we are informed that he has for now eight years been happily married, though childless.

Assuming that the microscope gave positive assurance that this was a case of real spermatorrhœa, and not of prostatic origin, the question is to be asked whether castration was a justifiable operation; and this question we think will be unhesitatingly answered in the negative by ninety-nine in every hundred, irrespective of such a process being forbidden by law even with the patient's consent. But laying this aside, the subsequent access of venereal appetite with apparent virile power remains to be explained. It is known that eunuchs, made so in manhood, may retain the former desires which they can no longer gratify; but that one who never before felt the sexual instinct should have it roused by the ablation of its proper organs is something passing comprehension. In the absence of a minute examination of the parts removed, we are almost enough like Didymus (whose name, by the way, signifies a testicle) to believe in an undescended testis and a scrotal tumour—in any other imaginable complication—rather than in the paradox thus seemingly recorded.—*New York Med. Gaz.*

Defect of Epiglottis.

In place of the epiglottis as normally fashioned, there was found by Dr. Eberth, in a female fifty-six years old, merely a fold of the mucous membrane, 5 mms. high and 1 mm. thick, with a crescentiform body of a fibro-cartilaginous consistence 3·5 mms. high. From the point of insertion of this fold of the mucous membrane of the pharynx spread two other wider folds, which turning backwards, under the pointed angle, united, and with the epiglottidean fold closed the three cornered glottidean cleft. There was no reason to infer that in this case the defect of epiglottis was a secondary abnormity, it was evidently congenital. There were only slight functional disturbances. The case is one seldom met with. Dr. E. cites as the only recorded case besides his own, that of Targiom Tozetti; even in this case, however, J. F. Meckel believes the defective epiglottis to have been the result of disease occurring after birth.—*Virchow's Arch.* xliii.

Yankee "Coroners" Law.

In addition to the Franco-Prussian difficulty, last week was rendered historically notable by a declaration of war between two New York coroners over the body of one Florence Scannel, who is supposed to have come to his death from the effects of a pistol shot wound received on the 3rd of December last. It appears that at the time of the occurrence, Coroner Rollins went to Bellevue Hospital with the view of taking the wounded man's ante-mortem deposition; but as Scannel refused to make any deposition, the visit can scarcely be said to have had any official bearing. A fortnight ago, however, Scannel changed his mind, and Coroner Flynn being sent for, received his deposition. The patient dying, Coroner Rollins proceeds to his residence, and meeting with objections from the friends of the deceased, has a police force placed in possession of the house, while he goes after Coroner Flynn. The latter individual meanwhile arrives at the house, has the police guard removed, and takes possession himself. Coroner Rollins returns, and being admitted after some difficulty, claims jurisdiction on the ground that he would, if he could, have made an investigation seven months ago, and further that he has retained Scannel's pistol (by what right does not appear). On the other hand, Coroner Flynn claims that he actually took the ante-mortem deposition, and as he has the friends of the defunct on his side, refuses to yield, and Coroner Rollins, fearing personal violence, is forced to retire from the field. Then comes the alleged murderer to protest that Coroner Flynn is "personally and politically opposed to him, and that he fears his safety will be jeopardized by a packed jury of Scannel's partisans."

Squabbles of this sort are of little general interest further than as they excite a wish among medical jurisprudents that coroners were of the nature of Kilkenny cats; but they serve to illustrate the absurdity of our present system of electing men to an important office on purely political grounds. One coroner with proper assistants would amply suffice for the city of New York; but even if there be more than one they should all be medical men with more regard for pathology than for politics, more solicitude for forensic medicine than for inquest fees.—*New York Med. Gaz.*

Medical News.

Refusing to Vaccinate.—At Leeds, on Tuesday, four persons, summoned for refusing to have their children vaccinated, were ordered to comply with the Act, and pay costs. One of them, a chemist, named Toulson, was summoned for the thirteenth time, and declined to comply, on the ground that he would not be the murderer of his child.

Post-Mortems at Guy's Hospital.—Another case was brought before the sitting magistrate last week, when, in answer to Mr. Benson, the applicant said he had not read the report of a similar case from the same hospital, which was dismissed some short time back. Mr. Benson said the complainant in the previous case had withdrawn it because he could not take the case to a superior court. He had spent £8 or £9, and if the applicant were to take the case through it would cost him between £50 and £60. Mr. Benson said he would commit Dr. Morrison, or the whole of the medical profession, if the applicant would bring proof that he would prosecute at the trial. The applicant, who said he was only a working man, and had no money, left the court evidently much disappointed.

Naval Medical Volunteers for the Continent.—The *Pall Mall Gazette* states that Deputy Inspector-General of Hospitals and Fleets, H. J. Domville, C.B., immediately after the first serious engagement between the French and Prussians, volunteered to proceed to the Continent, with a view of placing his services at the disposal of those who have charge of the wounded of the two armies, but the Lords of the Admiralty declined to give him leave. Several other eminent naval surgeons have followed the example set by Dr. Domville, with the same result.

Ecce Signum!—Some time ago we directed the attention of the proper authorities to the vilely fraudulent system adopted by many metropolitan traders in the matter of weights and measures. That our remarks were pertinent and judicious is now beyond question, as the following paragraph which we clip from the *South London Press* will show: Another batch of 64 South London tradesmen were fined on Wednesday for being possessed of short weights and measures. They consisted of 13 chandlers, 11 oilmen, 10 butchers, 5 each of publicans and bakers, 4 each of fruiterers and cheesemongers, 3 coal-dealers, 2 each of marine store dealers and grocers, and 1 each of gum merchants, iron-founders, costermongers, and leather-dealers. The total amount of the fines was £77 15s.

Vaccination Gratuities.—Mr. James Flexman, Surgeon to the South Molton Union Workhouse, has been awarded by the Medical Department of the Privy Council, on the recommendation of the Inspector of Vaccination, £3 12s., as an extra gratuity for the manner in which vaccination has been performed in that institution.

Health of Paris.—Small-pox still prevails in Paris. One hundred and eighty-seven deaths have taken place from that disease last week. Diarrhœa has also set in, and caused 71 deaths in the week.

Lunacy in Ireland.—The new Report of the Irish Lunacy Inspectors gives the total number of insane persons in Ireland in 1869 as 16,661. This is a decrease of 174 as compared with the number in 1860. In this period the number of lunatics at large has decreased from 8,991 to 6,579.

Health of Liverpool.—Relapsing fever is spreading at Liverpool, an increase of 116 cases having been reported last week over the previous one.

NOTICES TO CORRESPONDENTS.

*** Correspondents not answered in the current number should look at the notices in the following week.

NOTICE TO SUBSCRIBERS.—*The Publishers beg respectfully to remind those Gentlemen who have not paid their Annual Subscription, now overdue, that the most convenient mode of remittance is by Post-office Order, or cheque, which should be made payable, in England, to Albert Alfred Tindall; Ireland, Moffatt and Co.; Scotland, Maclachlan and Stewart.*

ACCEPTED papers received from Drs. Gordon, Thorowgood, Watson, Waring-Curran, H. M. Jones, Moore, Archibald Bleloch, Drysdale, &c.

DR. SUTTON, F.R.C.P., will deliver the Introductory Lecture at the London Hospital.

WAR MAPS.—We have been using this week Stannard's Bird's-Eye View of the Seat of War, being No. 7 of a series. It is a very finely coloured map, showing the points very clearly, and we have found it the most useful of all the maps we have come across in these times.

SUICIDE THROUGH PERSISTENT ABDOMINAL PAIN.

We observe in *The Midland Gazette* particulars of an inquest held at Sutton, upon the remains of a man named Huskinson, who committed suicide by hanging owing to a persistent abdominal pain from which he suffered for some months. A verdict of "temporary insanity" was returned. His medical attendant was baffled by his case as no actual disease of any organ could be detected during life. As the case was interesting, Dr. Waring-Curran obtained permission to make a *post-mortem* examination. He found all the thoracic and abdominal viscera healthy, but he noticed, we believe, the intestines tied down in places by firm bands of lymph; no doubt, from the history of the case, the sequence of localised peritonitis, which accounted for the dragging character of the pain, which was so severe and obstinate in yielding to treatment, as to drive the unfortunate patient to the extremity of self-destruction.

FORTUNE'S REVERSES.

We admire the terms in which our respected and much admired contemporary *The Graphic* narrates the trial of a man named Barrett, who alleged he was a surgeon, for receiving stolen goods, for which he was sentenced to twelve months' imprisonment. It appears Barrett had formerly been in prosperous circumstances, but was ruined by the failure of a "*Wheel-bang* Company (?) to whom he sold £13,000 worth of property in Holborn, for which he never got paid. *The Graphic* recommends that the directors of the said company should be invited to stand forward and agree to divide poor Barrett's penalty among them, as they did his property. In this we concur; but as it is not likely, we can only express our regret at the weakness of the law respecting the punishment of those scoundrels who keep deluding and ensnaring the public, and drive to desperation their unfortunate victims, such as Barrett.

DR. BELL TAYLOR ON THE CONTAGIOUS DISEASES ACTS.

We observe Dr. C. Bell Taylor, a Nottingham surgeon of repute and eminence in that part of the country, has just published in a pamphlet, Part II. of his Essay on *The Contagious Diseases Act*. The publication contains the substance of a paper read by Dr. Taylor before the Medical Society of London, and which originally appeared in these columns in January last, which shows how despotic measures not only fail to repress venereal diseases, but tend in a serious manner to increase them. Our author refers to one of Mr. Acton's letters published in THE MEDICAL PRESS AND CIRCULAR, wherein Mr. Acton stated "that unless the soldiers are carefully inspected and secluded, we cannot expect any benefit from the Contagious Diseases Acts. Dr. Taylor's pamphlet is a clever compilation of the opinions entertained by those who oppose the Act from a sanitary point of view, and as such will no doubt, be read with great interest, and we may safely add, instruction too.

APPOINTMENTS.

CORFIELD, W. H., M.B , Physician to the St. Pancras Dispensary.
DIXON, J., L.R.C.P.Ed., Assistant to the Extra Physicians of the Royal Hospital for Sick Children, Edinburgh.
HULKE, J. W., F.R.S., Assistant Surgeon, to be Surgeon at the Middlesex Hospital.
NICHOLLS, W. H., M.R.C.S., House-Surgeon at the Brighton Lying-in-Institution.
ORCHARD, T. N., M.B., Junior House-Surgeon at the Ardwick Dispensary.
THORPE, Dr. T. E., has been elected Professor of Scientific Chemistry at Anderson's University, Glasgow.
VINCENT, O., M.R.C.S., Surgeon to the Great Northern Hospital.
WALLIS, A. J., M.R.C.S., Medical Officer for the Dartington District of the Totnes Union.
WOOD, Mr. R. A. H., Resident Accoucheur at the Liverpool Lying-in Hospital.
WAR OFFICE—MEDICAL DEPARTMENT.—Staff Surgeon Major J. Crerar, from half-pay, to be Staff Surgeon Major, vice F. H. Baxter, M.D., who retires upon half-pay; Surgeon W. T. Harding, from the 56th Foot, to be Staff Surgeon, vice F. Oakes, appointed to the 56th Foot; Staff Assistant Surgeon T. B. P. O'Brien to be Staff Surgeon, vice E. H. Roberts, placed on half-pay; Staff Assistant Surgeon H. Sherlock to be Staff Surgeon, vice Staff Surgeon Major J. Gorringe, deceased.

VACANCIES.

District Lunatic Asylum, Clonmel.—Resident Medical Officer. Appointment in the hands of the Lord-Lieutenant of Ireland (See Advertisement.)
Newport Union, Mons.—Resident Medical Officer. Salary £40, with extras.
Salford Hospital.—District Surgeon. Salary £80, with board and residence.
Chester County Asylum.—Assistant Medical Officer. Salary £100, with board.
Whitechapel Union, London.—Public Vaccinator for the entire Union.

BOOKS, PAMPHLETS, AND MEDICAL JOURNALS RECEIVED.

Snuff-Taking, its Utility in preventing Consumption, &c. By Dr. J. C. Murray.
Two Cases of Rheumatic Insanity. By T. S. Clouston, M.D., &c.
Report of the Committee of the Medico-Psychological Association.
A Catechism of Health. By Dr. J. H. Bridges.
The Glasgow Medical Journal; Le Mouvement Médicale; Journal de Médecine Mentale; New York Gazette; The Chemist; New York Medical Journal; Nature, &c.

Marriage.

DRURY—FERRY.—On the 24th inst., at Bishopwearmouth Parish Church, Charles D. Hill Drury, M.D., of Pulham St. Mary, Norfolk, to Fanny, second daughter of Robert Ferry, Esq., of Sunderland.

Deaths.

BANKS.—On the 19th inst., W. Roger Banks, M.D., aged 38.
BENNETT.—On the 12th inst., Samuel Bennett, L.R.C.S.I., of Bruff, Co. Limerick, aged 63.
HUTCHINSON.—On the 9th ult., at Wynberg, Cape of Good Hope, James Hutchinson, F.R.C.S., late Secretary to the Medical Board, Calcutta.
MACLAREN.—On board the homeward-bound West India Steamer "Seine," Peter Maclaren, Surgeon, of Williamfield, Maudeville, Jamaica.
WELBANK.—On the 20th inst., Richard Welbank, F.R.C.S.E., of Clarence-place, Kilburn, formerly of Chancery lane, aged 73.

MR. RICHARD C. HOYLE was on Friday elected Medical Officer to the Barnstaple Union, at a salary of £13 per annum. There was only one candidate. After our remarks on this subject, we think one candidate was enough. We congratulate Mr. Hoyle on his victory, and the guardians in obtaining the services of a medical man at such a salary.

FEVER IN LIVERPOOL.

AT a recent weekly meeting of the Workhouse Committee, the medical officers reported that on Saturday last there were 328 cases of fever in the hospital, being an increase of 16 on the week. Thirty-four deaths had occurred during the week, being an increase of eight on the week. Three of the deaths had been caused by fever, being three less than the preceding week. The governor, in his journal, in an entry, said :—"I beg to draw the special attention of the Committee to the number of fever cases, namely, 370, under treatment this morning, which is equal to the accommodation both here and at Ashfield street. During three days 96 cases have been admitted, showing an increase much greater than we have hitherto experienced, and calling for immediate steps being taken to make provision to meet the requirements." With reference to the increase of fever in the town, Mr. Cropper said he had written to Mr. Wm. Rathbone, M.P., asking him whether it would be possible to obtain from the War Office the loan of field hospital tents, which might be erected on some vacant piece of land in a centre portion of the town, and to which fever cases could be removed. In the course of some further conversation several suggestions were made, some of the members advocating the temporary use of St. Anne's Church, which is about to be razed to the ground, as a temporary hospital, others holding that it would be far better to erect tents in Parliament fields, and on some suitable pieces of ground at the north and south ends of the town.

KEADY DISPENSARY.

The following letter was read by the clerk :—

Keady Dispensary,
15th Aug., 1870.

To the Board of Guardians,

ARMAGH UNION.

GENTLEMEN,—I enclose Dr. Rae's bill for acting as medical attendant to the Keady Dispensary for the past six weeks.

Dr. Rae has filled up all the books, and fully discharged the various duties of the situation during the above period.

I am, Gentlemen, your obedient servant,

LEEPER.

The clerk said that at the time Dr. Leeper obtained leave of absence for six weeks, the appointment of Dr. Rae as his substitute at a salary of £2 a week was noted in the minutes ; but up to the present the Commissioners have not given their sanction to the payment of the money. He wished to be instructed as to what he should do. He could not draw the cheque without the sanction of the Commissioners.

Mr. Best said that when the application was made for leave of absence there was a very small Board. The payment of Dr. Leeper's substitute was opposed by him and a few other guardians ; but they were out voted ; and since then no notice of this claim has been given to the guardians. He thought it should first be sanctioned by a special meeting of the Board.

Mr. Small.—This is a most unprecedented claim. Dr. Leeper very lately, by means of establishing a precedent, put this Union to an expense of about £200 a year. He now brings forward another precedent, by which every medical man in the Union may put us to an expense of twelve guineas a year more. We have always acted well to our medical officers—if they were ill we paid them, and paid a substitute. I am willing we should do so still, provided a proper ground exists for it—as, for an example, an accident, or illness caught in the discharge of public duty. But in this instance Dr. Leeper complained of rheumatism—a complaint to which many men of his age—myself for example—are subject. Mr. Kirk, M.P. for Newry, employs Dr. Leeper to accompany him to Germany to take care of his precious person, and Dr. Leeper accepts the employment, and takes advantage of the occasion to drink from the spas of Germany. He applies to us for liberty to go ; we give him the liberty, and we pay him his salary ; Dr. Leeper is well again, and I congratulate him on it ; but now here we have a claim for twelve guineas to pay Dr. Rae, which I oppose and will oppose as far as I can.

Mr. W. M. Kirk said that observations had been made in connexion with this subject which were quite uncalled for. Dr. Leeper had been twenty-seven years in connexion with the dispensary. During the whole of that time he never had sought for or obtained leave of absence for a single week. He was attacked with rheumatism of a most virulent type, and would have been obliged to give up. He took advantage of Mr. Kirk's going to Germany to try the German spas, and his illness had been removed. I thought the union had been a gainer by this because the service of an able and popular practitioner have been retained to the Keady dispensary, and the payment of the claim establishes no precedent.

Mr. Winder.—This was all discussed before.

Chairmun.—The commissioners have not yet sanctioned the payment of it. The question is, are we in the habit of paying a substitute for a medical officer who goes away in ill health.

Mr. Small.—Yes : if he be in ill health. I had rheumatism the other day ; but I don't call that ill health.

Mr. Best.—In Richhill we paid our doctor——

Mr. Small.—But that was a righteous case ; that man got his thigh broken, and he got it broken again, in the discharge of his duty to this Board. But I consider this the most ridiculous claim I ever heard of.

After some further conversation, the Board directed the clerk to refer the matter to the Poor-law Commissioners, and to request an answer, and then to refer the question to a special meeting of Guardians on the 6th proximo.

LIMERICK UNION

THE MEDICAL OFFICER OF CASTLECONNELL DISPENSARY DISTRICT.

The Clerk read a letter from the Poor-law Commissioners, stating that they had dismissed Dr. Porter, medical officer of the Castleconnell dispensary district, by sealed order, as they believed the charges made against him by the committee of management to be correct.

Dr. O'Sullivan enquired whether Dr. Porter had asked for a sworn enquiry into the matter, and if so, whether it had been refused by the Commissioners.

Mr. Gabbett, Secretary of the Committee of Management, said he would inform the Board of the facts.

Dr. O'Sullivan said he merely wanted to know whether an enquiry had been refused.

Mr. Cronin enquired whether it was customary for the Board to be informed of the business of the committee.

The Chairman replied in the negative.

Mr. Gabbett said a meeting of the Committee of Management had been held by direction of the Poor-law Commissioners for the purpose of giving their observations on a report furnished by Dr. Porter to the Commissioners. The Committee framed a report on the subject, and directed it to be forwarded to the same body. At that meeting a member stood up and produced an anonymous letter which it was not necessary for him to speak about. They sent it to the Commissioners for their opinion, accompanied by a resolution, to which they had agreed. He (Mr. Gabbett) as secretary, sent a copy of that resolu-

tion to Dr. Porter on that day, and on the succeeding day he received a letter from Dr. Porter, declining to accede to the request of the Committee by sending in his resignation. He further stated that he would have a sworn inquiry, and as far as he (Mr. Gabbett) recollected, added that he hoped his accusers would not be his judges. In the course of that week I got a letter from the commissioners containing their reply to our report, and to our resolution forwarded to them with the anonymous letter. I did not think it necessary to bring that letter here. They (the commissioners) wrote to Dr. Porter requiring his explanation, and I believe Dr. Porter wrote a reply, which was not satisfactory to the commissioners.

Mr. Tinsley said there was one thing that had escaped Mr. Gabbett's notice in reference to Dr. Porter's letter, but which he (Mr. Tinsley) recollected. Dr. Porter, as a person charged with a criminal offence, asked the commissioners to send him a copy of the letter which he was charged with writing, and as soon as he should have received it he would then give them a reply. The commissioners' reply was the sealed order dismissing him from office. He would ask Mr. Gabbett whether this was correct.

Mr. Gabbett repeated that so far as his recollection of the letter was concerned he believed the statement of Mr. Tinsley was partly right and partly wrong, and he (Mr. Tinsley) could give no more than his opinion respecting the letter, and neither could he (Mr. Gabbett). It is true that with the letter they furnished me they also furnished me with a copy of a letter they wrote to Dr. Porter. In the first place they say they asked a statement from Dr. Porter with reference to the anonymous letter. They stated in their letter that he required from them a copy of the letter, with the date of its receipt and the name of its recipient. They, the Commissioners, in their letter to Dr. Porter, declined to do this, and gave it as their opinion that this, far from being an explanation, was an aggravation of the offence; and they wound up by saying that in their opinion the anonymous letter was written by himself (sensation). In that particular your statement was incorrect, and I now state it because you brought it out of me (hear, hear).

Mr. Tinsley said when the letter was received, the meeting dissented, and stated their opinions on the acts of the Commissioners, which they considered most arbitrary. When any man was charged—no matter how humble his rank might be he should first be tried. He cared nothing about Dr. Porter, and knew nothing about him. If he was guilty he ought to be tried, but what he (Mr. Tinsley) complained of was that he was condemned behind his back, found guilty—the strongest censure was put upon him—he was deprived of the means of earning his bread—he was dismissed by sealed order without the option of an investigation, at which he might have had an opportunity of defending himself. If an enquiry had been instituted, and the Commissioners had come to that resolution, he would say they would have been perfectly right; but Dr. Porter had no trial at all. The first day there were certain charges made against him and he apologised—he (Mr. Tinsley) used the word advisedly—and a large number of the committee accepted the apology. This was in reference to the principal charge brought against him that day. A gentleman produced this anonymous letter, and another gentleman stated that he believed it had been written by Dr. Porter. The latter then stood up greatly excited, and in the strongest possible manner repudiated the charge, and denied that he knew anything about it. He beame so excited that he was requested to leave the room, which he did. He was subsequently called in and informed that the majority of the Board had resolved that he should be called upon for his resignation. He (Mr. T.)would state that several of the members were under the impression that he would be called on for his resignation by the Commissioners, but it was afterwards decided by the Secretary that it was the Committee who had called upon him for his resignation. The doctor would not get an hour to make his defence, which he (Mr. T.) thought extremely harsh. Even though he were guilty of the crime laid to his charge, he should not have been convicted and judged in the course of a few minutes, without an opportunity of making his defence. He did not wish to stand up as an advocate of his innocence, but he should be held to be innocent until found guilty. At the last meeting it was perfectly obvious that he could not hold his position at Castleconnel. If he were even innocent he could not hold his office in the union.

Mr. Tinsley.—It would be better to ask the Commissioners to withdraw the sealed order, and to permit the doctor to ask for an enquiry. We think it better that a termination should be put to this unseemly and unpleasant piece of business that has been going on at Castleconnell such a length of time. I may say that I made it my business to enquire how he discharged his duty, and I have been told that he discharged it with ability and attention. He may have had private faults, but I must say that the large majority of the people of the district I was in had no fault to find with him; and it is not for any dereliction of duty that he is discharged.

Dr. O'Sullivan again put his previous question as to whether an enquiry had been refused.

Mr. Browne.—There were assertions made here against myself as a member of the committee; for from the manner in which Mr. Tinsley has put the case before the members of the Press here, it appears to be a most outrageous thing.

Mr. Cronin.—No mistake about it.

Mr. Myles.—Order.

Mr. Brown.—Why it was not Dr. Porter who was on his trial, but the committee. The members of the committee were on their defence, for they were accused of dereliction of duty. It was I who moved the resolution that he be called upon to resign; and I did it entirely irrespective of those letters; and the very words I used were that—Irrespective of those letters there was quite sufficient in what occurred—coupled with what took place before—to show that Dr. Porter was unfit to fill the position he held in Castleconnell. It was on the grounds of his bringing a charge against the committee, and which he was obliged to withdraw—that our charge against him was based. If these letters had never been brought, the majority of the committee would have voted that a resolution calling on him to resign be forwarded to the commisioners.

Mr. Tinsley.—It is right for me to say that Mr. Bourke, P. L. I. stated that his qualifications as a medical man were unexceptional, and I would take his opinion respecting his skill before Mr. Gabbett's. He (the doctor) complained of want of accommodation at both stations. In one of them he had no place to privately examine patients, owing to females occupying both apartments of the house. And in reference to this he complained that his report had been "cushioned." All this shows the downright necessity of having the Press present to report such proceedings; for had they been present we would have had an accurate report of the entire matter, and gentlemen would not now be contradicting each other in this unseemly manner. An investigation should take place, and this unfortunate man should not be prevented from getting a situation in any part of this country.

After some further discussion, on the motion of Mr. Brown, seconded by Mr. W. Laffan, the following resolution was passed unanimously:—"That the request of the Castleconnell Dispensary Committee to the Poor Law Commissioners, dated August 22nd, to withdraw their sealed order dismissing Dr. Porter, and allow him to resign, be complied with; or if they find they must adhere to their sealed order, that they will grant him an inquiry if he demands it."

BELFAST BOARD OF GUARDIANS.

VACCINATION OF CHILDREN.

Dr. Martin returned a list to the Board of 538 persons in his district who had not complied with the Act, in having their children vaccinated.

Mr. Humphrey, relieving officer, stated that in Dr. Rea's and Dr. Newett's districts there were 700 cases. They were proceeding with the inquiry, and action had been taken to enforce compliance with the Act in several of the cases.

Mr. T. Wilson, relieving officer, said he had completed Dr. Browne's list of 151 cases. On inquiry, it was ascertained that in 98 of the cases the children had been vaccinated, and with regard to 24 of the cases legal proceedings had been taken before the magistrate.

Some conversation took place as to who should take charge of this matter, as the relieving officers complained that it interfered too much with their other duties.

Some members thought that the medical officers were the proper parties to take charge of this matter, but the majority of the members considered that the relieving officers were the most suitable persons to be entrusted with it.

Mr. Gaffikin asked was there not some expense incurred in getting the law enforced in this matter.

Mr. Humphrey said there was expense and very considerable trouble.

Mr. Teirney—It would be a good way if the magistrates gave the relieving officers the fines in each. I'll warrant you they would soon hunt them all up then. (Laughter.)

Mr. Gaffikin—Oh, I think if they got a shilling in every case in which there was a conviction, it would do very well.

Mr. Humphrey—The magistrates can give that if they choose, as well as full expenses.

Mr. Gaffikin—It is the least the relieving-officer should get for his trouble. (To the relieving-officers)—We'll give you a shilling in each case.

Mr. Teirney—Ah, give them all the fines. That will never make them catch them. (Laughter)

Mr. Gaffikin said he understood a great many parents got their children vaccinated by private medical gentlemen, and it would save a great deal of trouble to the relieving-officers, as well as inconvenience and expense to themselves in being summoned, if they sent in the certificates of vaccination to the proper parties to receive them. Ont of 600 returned as not complying with the Act, there might not be 200 who would be required to be summoned.

The relieving-officers were then directed to proceed at once and summon all the defaulters in each of the districts.

The remaining business was routine.

CORK UNION.

A COMMUNICATION from the Commissioners was also read, asking whether the resolution of the Board proposing to increase the salaries of the several medical officers of the rural dispensary districts of the union by £20 per annum, was intended to extend to the medical officer and apothecary in the Queenstown district, whose salaries had been lately increased.

It was decided to inform the Commissioners that Dr. Lawler was included in the resolution, but the others were not.

DR. A. WILTSHIRE has treated successfully five cases of delirium tremens with the large doses of digitalis that have been previously recommended. We still should hesitate at these half-ounce doses of tincture of so uncertain a drug.

ADDRESS AND PRESENTATION TO WM. SCOTT, ESQ., M.D., J.P.

A MEETING was held in the Aughnacloy Court House on Saturday, the 20th instant, which was largely attended by the gentry of the town and neighbourhood, the object being to present an address and testimonial to their eminent and respectable fellow-townsman, Dr. Scott, J.P., on the occasion of his resignation of the charge of the Aughnacloy Dispensary District, with which he has been for many years connected, and where, by the kind and zealous manner in which he discharged his duties, endeared himself to all. The poor ever found him ready to minister to their ailments or console and advise them in their distress, and to all he was the able physician and genial friend. It is hoped that his retirement from the onerous public duties he has hitherto so efficiently discharged will enable him to pursue with his wonted vigour his arduous professional duties, of which the constant attention he has always bestowed on the hospital, irrespective of other calls on his valuable time, form no inconsiderate part.

HEALTH OF DUBLIN.

IN the Dublin Registration District the births registered during the week ending August 20th, amounted to 180—90 boys and 90 girls. The average number in the corresponding week of the years 1864 to 1869 inclusive was 152.

The deaths registered during the week were 128. The average number in the corresponding week of the previous six years was 133.

Seven deaths resulted from fever, viz. :—2 from typhus, 3 from typhoid or enteric, and 2 from simple continued fever.

Scarlet fever proved fatal in 5 instances, and measles in 2.

Eighteen deaths were ascribed to diarrhœa, and 1 to simple cholera.

The deaths of 11 children were referred to convulsions.

Bronchitis caused 5 deaths, and pneumonia or inflammation of the lungs 1.

Four deaths were attributed to heart disease.

Paralysis was the cause of 3 deaths, and apoplexy of 1.

Two deaths from kidney disease, and 1 from nephria, or Bright's disease, were registered.

Diseases of the liver caused 3 deaths.

Five deaths from violence were registered, 4 of which were from accidental causes, and the fifth, which occurred in the Richmond Hospital, was returned as "fracture of skull," but how caused is not stated.

Of the deaths registered 53 were of persons under 5 years of age, and 25 were persons 60 years old and upwards.

DEATH OF MR. CLEMENT, M.P. FOR SHREWSBURY.

WE regret to announce the death of Mr. W. J. Clement, M.P. for Shrewsbury, in the sixty-sixth year of his age. He was born in the town, which he has represented in Parliament since 1865. He was partially educated there, but afterwards went to Edinburgh. In 1844 the Royal College of Surgeons of England elected him an Honorary Fellow. He obtained the Fothergillian Gold Medal for his essay on "The Urinary Organs," and has contributed some practical papers to the medical journals.

DEATH OF DR. ALEX. H. COOKE.—We regret to annouuce the demise of Alexander H. Cooke, Esq., M.R C.S.E., son of the late Rev. Dr. Cooke, which took place on Friday, at the residence of Mr. R. W. Skelly, Greenwood, Saintfield, where he had been on a visit sinced Wednesday last. The deceased was Assistant-Surgeon in the Antrim Artillery, and was much esteemed by all who knew him. He had been in delicate health for some time, and was in a weak state when he arrived at Mr. Skelly's, from Carrickfergus. Dr. Smyth, of Saintfield, was most attentive to him, but medical skill was unavailing.

DEFECTIVE ARRANGEMENTS OF DISPENSARIES.

TO THE EDITOR OF THE IRISH MEDICAL ASSOCIATION JOURNAL.

SIR—In this period of progress, I cannot suppose that the obvious defects of our medical institutions will be allowed to remain unremedied. When the attempt is being made those who are interested may deem the following circumstances, in reference to our Dispensaries deserving of their consideration. There are seven hundred and eighteen Dispensary Districts in Ireland, which are attended by seven-hundred and ninety-six medical officers. The Poor Law Valuation is £13,117,769, which gives an average valuation of £18,369, for each district, and of £16, 480 for each of the seven hundred and ninety-six medical officers. If each medical officer could be located in a district of £16,480 a year, which is about a rental of £20,000, the proprietary and occupiers of the the district would afford means of enabling him to support the position in which he ought to be placed; but an examination of Poor Law Commissioners reports shows that there are one-hundred and twenty-nine dispensary districts, whose valuation is under £10,000, and of these that forty-one are under valuations of three, four, five, and £6,000. Several of these small dispensary districts are, it is true, joined to others to form one, for a medical officer, but the property of many districts is manifestly insufficient to afford him practice, which, of course is his chief object. Again, the average population of seven-hundred and eighteen districts is eight thousand, and seventy-six, and is only seven thousand two hundred and ninety-seven for each of the seven hundred and ninety-six medical officers. This population with a valuation property of £16,480 if available, would answer pretty well. But there are one hundred and fifty dispensary districts whose populations are very limited, five are under two thousand; twenty-two under three thousand; forty-seven under four thousand; and seventy-six under five thousand. Though some of these districts have considerable property, most have not, and when both elements for medical practice—property and population—are limited, the local authorities have less inducement to give the medical officer a fair salary, or when he is in the fit condition to retire, to superannuate him fairly. On the other hand, where there is population to be attended, and property to be rated, salary and superannuation will be much more freely given. Again, I find that each of forty-four dispensary districts to each of which only one medical officer is attached, has an average population of fourteen thousand one hundred and fifty-two, some sixteen thousand, twenty thousand, and twenty-three thousand, that the property valuation of each averages £26,658, and that the districts average thirty-two thousand and seventy-two acres, or fifty square miles. It appears to be impossible for one person to attend the sick of so large a population scattered over so great an area, even some having an area of forty thousand, forty-eight thousand, seventy-two thousand, and ninety-three thousand acres, and as the property in each is large, there is evidently room for change and improvement. These facts show that a re-arrangement of the dispensaries of many districts is desirable, for which there is provision in the Medical Charities Act. The public at large, but particularly the medical officers, and indeed, the whole medical profession, owe a great debt of gratitude to Lord Athlumney, for the pains which he bestowed in preparing and passing that Act, the sixth clause of which Act empowers the Boards of Guardians to divide the Unions into so many dispensary districts, "having regard to the extent and population, as may appear to them to be necessary," subject of course, to the approval of the Commissioners. With such a power, it was natural that guardians of influence should wish to establish dispensary districts, for their own more special convenience, and hence we find that many were established with too limited population and property, and some with too great a population and area. Several of the former dispensaries were located in this manner, and the same influence caused the continuance of the institution. If two such limited dispensary districts were immediately contiguous, to be placed under one medical officer, it would be all right, but when this is not the case, as often happens, the establishment of small dispensary districts has many disadvantages. It apparently offers a situation and a field of practice for medical men, and thus induces too many to enter on that profession, and to locate themselves where, though they may have a tolerable salary, they have not the elements for a fair practice—that is, property and population. Political economists tell us that where those offering for employment are even only very few more than there is a demand for, these few will cause the wages of all to be much lower than if there was employment for all; and on the same principle an excess of unemployed medical men, or of medical men located in districts which cannot afford them fair practice, is sure to lower the professional earning that would be had under a dispensary system where each of those institutions had sufficient population and property. At present the retiring allowance of the dispensary medical officer is charged on the property of the electoral divisions of the dispensary district, unless when the whole union forms that district, which is only the case in a few instances. In England the superannuation is charged to the property of the union at large, and until similar legislation takes place here, the guardians and members of small dispensary districts will be slow to give fair superannuations to their medical officers, or to superannuate them at all. If, for instance, either of the five medical officers of the Donegal Union were in a condition to be superannuated, how much more likely would the dispensary committees be to give fair superannuations when they know that the retiring allowance would be charged on the union property, £34,621 yearly, rather than as now on the district valuations, ranging from £9,665 to £4,258, and there are many unions and districts similarly circumstanced. Union rating in place of electoral division rating would remove this objection, and would also induce the guardians of these small dispensary districts to give higher salaries, and yet I have not seen that the Medical Association, or any medical party* has taken any step in favour of union rating, a measure so immediately tending to benefit the Poor-law officers of all classes. Had the dispensary districts been satisfactorily arranged at first, of course, it would have been far better, but though it may appear difficult to do so now, that difficulty would give way on the work being undertaken in a determined spirit. The above returns show that there is a necessity for much improvement, and if the Poor-law medical officers apply to Parliament early in the next session, there is a likelihood that they will get rid of the thousands of wealthy pauper patients, and that their condition will be much improved.

DENIS PHELAN.

HYDRATED chloride of aluminium is said to be a capital antiseptic. Mr. John Gamgee having introduced it, we may expect soon to find it freely in the market.

MR. MASON is trying to remove the deformity caused by a contracted cicatrix after a burn, by utilizing M. Revendin's method of skin grafting.

---

* I find that I have overlooked a petition to Parliament from the medical practitioners of the town of Enniscorthy, which petition contains a series of excellent resolutions on union rating, and on other important matters respecting dispensary and workhouse medical officers, and was presented by Mr. M'Mahon in 1864.

A NEW CAUSE OF VENEREAL CONTAMINATION — TESTED BY PRACTICAL OBSERVATIONS AND INOCULATIONS FROM A HITHERTO UNRECOGNISED SOURCE — INOCULATION AS A MODE OF TREATMENT.

By Mr. Morgan, F.R.C.S.I.,

Professor of Surgical and Descriptive Anatomy, R.C.S.I.
Surgeon to Mercer's and the Westmoreland Lock Hospitals.

(*Continued.*)

These cases I have selected from many others under treatment, and where the inoculations have been made so as to test the question of the source of the soft-chancroid, or usual sore.

It seems to be essential that the system shall be under the influence of the constitutional poison in order that the vaginal discharge may be capable of producing the characteristic pustule and sore. My inoculations, I think, tend to this conclusion ; but I hesitate as yet to pronounce it as an invariable rule.

In the series of cases tested and treated by the inoculation method, the result has been most favourable in many instances, especially in those who were most prostrated by the disease, and thoroughly cachectic. No matter what our prejudices may be, or the difficulty that we may meet in explaining satisfactorily the mode of cure, we should not, I think, neglect any proposition based on practical results, which may enable us to combat the varying phases, and subtleties of the disease with greater prospect of success. The progress made towards recovery in cases of great intensity as in those forming Series 3, 9, was most striking, and was even more remarkable in a case of acute rupia, lately under my care (occurring as the first eruption after a primary sore) in a girl of twenty, who showed the most striking improvement when inoculation had been performed; two inoculations failed, the third succeeded; the rupious crusts fell off and healed most satisfactorily within a fortnight. Every one conversant with the subject of constitutional syphilis has seen the inexplicable freaks and spontaneous cures which occur; but where after inoculation we see almost every case undergo a marked improvement, it is impossible to attribute this to some accident or cause unknown.

I do not repeat the inoculation till the previous one has healed, and sometimes this lasts three weeks or one month, and it is a remarkable physiological fact, that the more infected and debilitated the patient, as in Series 3 and 9, the greater is the resistance to the inoculation, and, when produced, the greater is the tendency to heal ; while in the more vigorous and less depressed cases, as in Series 2, the contrary holds good.

The natural shrinking from the responsibility of inoculating a new virus on a patient probably already much reduced in strength, and suffering from the full influence of the venereal poison, has been one of the chief difficulties in the consideration and application of this mode of treatment, which, at first sight, may be distasteful to the ideas either of the surgeon or the patient. However, if it has been questioned that good results have not invariably followed its practice, certainly no injurious ones have been recorded of such a nature as to forbid the method or form the basis of any objection to its use.

Since the initiation of the idea, by M. Auzias Turenne, that there was such an attainable condition as syphilization, or a stage of non-receptivity, of the venereal poison, much attention has been directed to the subject. Sperino, of Turin, and Boeck, of Christiania, have followed up the idea, and the latter has particularly applied it on a large scale for the cure of the worst forms of syphilis. While the idea entertained by Auzias Turenne in 1844 was that such a saturation of the system was arrived at, that immunity from the effect of any further syphilitic influence was gained, Professor Boeck candidly admits his inability to explain the process, but that he has found by practice that the method of repeated inoculations has been satisfactory. Others believe that the beneficial effects of inoculations merely consist in the depurative action on the

system by means of counter-irritation, such as would be obtained by blistering or the use of a seton, and have imitated the process by the use of tartar emetic ointment, or the application of blisters. Others, as Professor Faye, are inclined to think that a temporary immunity is gained by the over-stimulated skin, when the method used by Professor Boeck is put in practice, of keeping up a perpetual series of re-inoculations on the patient's body. The practice has been so often referred to that it is hardly necessary to describe it here, more than to state that Boeck uses the matter of what is described as being the hard or infecting sore, having previously irritated the surface by the use of a stimulating application, and that he renews the inoculations from each succeeding sore until immunity or non-receptivity is reached, and the symptoms yield.

The source from which I have derived the inoculation agent has hitherto, I believe, never been tested. I do not assume that it is the secretion of a "hard" or "soft" type of sore; but a muco-purulent discharge; the result has always been the characteristic pustule and inoculable sores of the so-called non-infecting or soft ulcer, and the patient from whom the inoculative agent is derived never was known to have had a true infecting type of sore, or enlarged inguinal gland, and yet is thoroughly infected; as the statistics of the Lock Hospital here infallibly prove that quite irrespective of the form of the primary sores constitutional signs are almost invariable sequences; indeed, some of the most intensely syphilitic patients have been those who suffered from the phenomena usual to the soft or non-infecting type of sore.

It appears with regard to the inoculative power or receptivity of some patients, that the differences are very remarkable, and bear a ratio to the apparent saturation of the patient with the syphilitic poison. This is very remarkably shown and illustrated by the results of some of the inoculations of Series 12; the contrast of the effects of inoculation with the same drop of matter on different subjects is highly interesting, and goes far to prove that a progressive state of non-receptivity whether depending on constitution, state of health, or syphilization, is capable of being obtained.

From a drop of matter, or vaginal secretion, of Series 12, I inoculated No. 1,193 on the side of the abdomen on July 7th. This patient was at the time rather florid, and in tolerably good condition, and was but a little over a year living irregularly; she was aged about eighteen, and was suffering from patches around the vulva, alopecia, and nocturnal pains; in fact, in the early stage of syphilitic evolution, but in rather good health. The inoculation was performed with a new pin (so there could be no error on the score of cleanliness); a characteristic pustule was produced, becoming a sore within a week, and a most perfect chancroid with characteristic edges surface and discharge, formed. The sore became fully formed, and now has the appearance and size of the illustration (Series 13), August 18th, being more than five weeks after its first inoculation. The general condition is immensely improved, the pains and patches having disappeared completely. It is evident in this case, that the inoculated matter was most effective as to its result, and that the soil in which it was sown was eminently suited to its fructification.

In contrast to this, the next case is very remarkable. I inoculated from the very same drop of pus, within the same five minutes, on the same part of the body, and with a new pin, No. 1,075, a strong, healthy patient of twenty-one, who had not been more than a few months living irregularly, and was suffering from early constitutional signs. She had been inoculated on June 13, and at this time (July 7th) presented absolutely a nearly healed sore, the result of inoculation with No. 1,093. The effect in this case was by no means so persistent as in the former; the pustule produced was characteristic, and resulted in a perfectly-shaped chancroid by the 14th. This sore became about the size of sixpence, and then commenced to heal. The patient left Hospital, July 4th, free from all constitutional signs, having been sixty eight days under treatment.

At the same time, and from the same sore, and on the same part of the body, I inoculated No. 921, a patient suffering from intense chronic syphilitic intoxication, having had iritis, nodes, rash, and gummata, and who had been inoculated on four occasions previously; in three days a pustule was fully formed, which became a feebly marked ulcer, and healed within fourteen days from its first appearance.

In like manner, I inoculated at the same date No. 988, who had been intensely syphilitic, and had been ten times inoculated as referred to at Series 3. The pustule formed was imperfect and feeble, and the ulceration healed within one week. This patient was discharged August 1st, having been 133 days under treatment, perfectly free from all signs.

In like manner, and at the same date, I inoculated No. 1,000 (forming Series 9), who had been eight times inoculated, producing but an ill-formed, though characteristic, pustule and small chancroid, which healed within fourteen days.

In like manner, and at the same time, I inoculated No. 1,083, a patient not before inoculated, but who had suffered from the most intense syphilis for over eight months, having had double iritis, papular rash, patchy ulceration of the mouth and throat, extreme alopecia, pains and cachexia. A characteristic pustule formed, succeeded by a sore equalling a shilling in size, which lasted for sixteen days, when it presented the appearance given in the illustration (Series 14); now healing rapidly (July 29th). This patient left the hospital August 11th, thirty-five days after the production of the inoculation, and three days after its being healed, free from all constitutional signs, though thin and still delicate looking.

On an analysis of these cases, it is evident that inoculation from the same particle of pus produced different effects and sores of a persistence and character proportioned to the condition of the patient.

The illustrations show this: In the first (Series 13) the sore is of characteristic shape and considerable size, having existed for more than five weeks, but the patient was in comparatively good health, and had not suffered from any severe constitutional manifestation; while in the second illustration (Series 14), the reverse exactly was the case, the patient having suffered severely, and never having been before inoculated; here the sore was well marked and of tolerable size and persistence, but soon healed.

A consideration of the other cases given, will show the gradations of non-receptivity.

Thus, No, 1,075 who was at the time under the influence of an inoculation—a stout and rather florid patient—not having suffered very severely from constitutional signs, developed a sore less intense, and sooner disposed to heal, than the preceding.

No. 921, who had been intensely syphilitic, and who had been inoculated four times, a feebly marked ulcer only was produced, which healed within a fortnight.

No. 998 (forming Series 3), a patient who had been greatly prostrated by syphilitic constitutional intoxication, and who had been ten times inoculated, produced a sore which healed within a-week.

As these cases were all inoculated from absolutely the same drop of pus, at the same time, and with a different instrument, there could be no possibility of the inoculations taking place from mingled or diverse pus; and the conclusion is pressed upon us that there existed some condition in the patient which resisted the formation of these pustules and sores, and was antagonistic, or non-receptive of the poison so freely inoculable on others, and derived from a patient at the time, showing evidences of infection. Difficult as the question is, these instances go far to bear out the theory of syphilization; the activity of the resulting inoculations having borne an exact proportion to the intensity of the syphilitic manifestations, and becoming

ARTIFICIAL CONTAGIOUS SORES

PRODUCED BY INOCULATION.

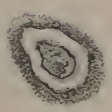
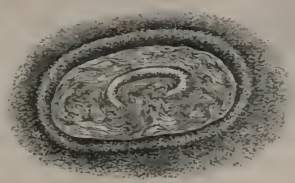
SERIES 13.
Result of inoculation from a vaginal discharge on a patient not highly syphilized forty-two days after inoculation.



SERIES 14.
Result of inoculation from the same drop of pus as that causing Series 13, twenty-two days after inoculation, the recipient being highly syphilized at the time.



SERIES 15.
Result of inoculations from a vaginal discharge on a patient not highly syphilized forty-six days after inoculation.

gradually non-effective where the patient had been frequently inoculated, as in the last example quoted.

Again, with regard to the duality of the venereal poison, these instances are instructive: if the virus was the virus of a simple soft or chancroid sore, it should have been regularly inoculable, or productive, in all these cases; and if the virus of the true chancre, or infecting sore it should, according to theory, have been inoculable in none, at least with great difficulty. Yet, though all the patients were suffering from constitutional manifestations, the immediate results in each were widely diverse, and, as I have detailed, proportioned to their syphilized condition.

I have selected another case to illustrate this remarkable property of the virus, as it might be supposed that the particle of pus in this case just alluded to, had some special quality. The illustration (Series 15) represents the result of an inoculation performed on June 30th, mentioned when detailing Series 11. I inoculated several persons with the vaginal discharge of No. 1,185, who had been in hospital twenty-nine days when this was performed; the patient operated upon was free from any rash or severe signs, but had rather extensive patches and superficial ulceration about the vulva, and remarkable syphilitic ulcerations between the toes, with some large papulo-pustular rash on the feet; she had some nocturnal pains, and was a married woman; infected by her husband, to whom she was only a short time married, and was now about six months pregnant; otherwise free from any syphilitic signs. The pustule was most marked, and the resulting sore remarkably developed, having attained the size and appearance shewn in the illustration, Series 15.

August 15th, now forty-six days from the date of inoculation, all the other inoculations derived from this source (Series 11) and practised on eight other patients, have healed, thus:—

No. 1,093.—Inoculated June 7th; formed a perfect sore, equalling a fourpenny piece in size, by July 12th, and healed by the 20th July, the patient having been before inoculated, and being intensely syphilitic, pregnant, and suffering from patches, pains, and rash.

No. 1,098.—Inoculated June 27; formed a perfect sore, equalling a fourpenny piece in size; fully formed by the 10th July, from which date it commenced to heal; the patient had been before inoculated, and was suffering from patches, pains, alopecia, hoarseness, and copious papular and roseolar rash. She was a married woman infected by her husband, and was discharged July 20th perfectly free from all symptoms; fat, and in good condition, having been treated only with inoculation and hot air baths.

No. 1,112.—Inoculated June 27th; suffering from papules, alopecia, and pains; had been before inoculated; sore formed by 10th July, equalling a sixpence in size, and healed by the 30th.

The patient's condition greatly improved at that date; she is now a ward-maid in the hospital.

It is here remarkable that the only patient who did not present evidences of a severe nature, and who had not been long under the influence of the constitutional infection, afforded the best nidus for the implantation and growth of the inoculated virus. The cases tested on the 27th were inoculated from the same drop of pus, and that from which the illustration, Series 15, is taken was inoculated, though not from the same particle, yet from the same source, viz., the vaginal discharge of the same patient, No. 1,185, whose history has been before reviewed at Series 11; the theory of non-receptivity or syphilization, attainable by the process of the late Aurias Turenne, doubtless receives some support from these results, and goes against that of "elimination" or "derivation," by which some have thought the inoculation treatment acts. In *Hay's American Journal* of last month, the results of some cases, lately treated by the inoculation method, have been reported by Professor Bumstead, and instances are given in illustration. The question is thus put by Professor Bumstead—"Is syphilization to be recommended for general adoption?" He answers—"In the preceding pages I have said much in favour of this method of treatment, and I have endeavoured to give to its full credit, from what I have personally witnessed, and from the accounts of others, I believe that it is a very effective method for the treatment of syphilis."

But, on the opposite side is put the discomfort caused by submission to the treatment, and the markings caused by the cicatrizations of so many pustules.

This, no doubt, is to be considered, and it is a serious matter when applied to the treatment of a disease which is not necessarily fatal, as it brands indelibly the body, with evidences of having suffered from an affection so repugnant. I believe it would be most important to avoid this branding, not only for the sake of the moral, but the physical discomfort attending it—so great, indeed, that it is now urged as the chief obstacle to the practice of this method, which, though not more inexplicable, and by no means so astonishing, as that vaccination should be a guarantee against small-pox—seems, in many extreme cases, to be attendant with such good results that, as above quoted from an unbiassed and independent observer, it is found to be "a very effective method for the treatment of syphilis."

From my experience with the inoculation derived from the vaginal discharge of patients under the syphilitic influence, I believe that the chief objection, arising from the discomfort and markings caused by the continuous inoculation, may be obviated to a great degree. Thus, in the cases to which the inoculation method is specially applicable, where the syphilitic cachexia is intense, as in Series 3, 6, 7, 8, 9, already related, the inoculations were more persistent, and did not require that repetition of the pustulating and scarring process which is essential to the syphilization method of Professor Boeck. It is also remarkable that the receptivity of the patient seemed to bear a ratio to the condition and the manifestations of syphilitic intoxication, as fully illustrated by the Series 13, 14, and 15.

As to any inconvenience caused to the patient I have seen very little. The largest resulting sore I have witnessed is that of Series 13. The pustule produced by the inoculations is hardly painful, and the resulting ulcer is not very sensitive, or likely to prevent the patient pursuing any ordinary avocations. It is to be borne in mind that the higher on the side of the abdomen the inoculations are made the less inconvenience do they give.

The question of the character of the sore, from whence the inoculative virus is derived, is a matter of interest. Boeck and others profess to practise the method from the hard, or infecting sore, when previously irritated; though, in the earlier experiments, the pus of chancroids was used. However, the result in either case is a characteristic pustule peculiar to chancroidal inoculation. In the late cases related by Bumstead the matter used for inoculation was, on several occasions, confessedly that of the soft, or chancroidal sore, yet the resulting pustules were similar. The appearances of outline, and surface in the inoculation sores I have represented are very characteristic of the chancroidal sore; yet they were produced neither from a sore or pustule, but from a vaginal discharge, as I believe, necessarily occurring in a patient under the constitutional syphilitic influence.

The same characteristic pustules have been produced by Dr, Gjör, from the secretion of mucous patches. I have myself produced successful inoculations from the mucous patches of a child hardly two years old suffering from constitutional syphilis.

Dr. Richardson (*Dublin Quarterly Journal*, August, 1870, p. 86) relates a similar case of auto-inoculation produced from a mucous tubercle in an adult. It is evident from my inoculations that vaginal discharge furnishes a more vigorous pustule, and a resulting sore which, by its less evanescent property, obviates one of the chief objections at present brought against the process of syphilization, or the treatment by inoculation.

II.—The Conservatism of Modern Surgery.

(*Continued from page* 159.)

One at least of the most important elements in the successful treatment of such cases is to be found in the great principle of rest, as carried out by means of apparatus which shall at the same time perfectly support the limb and retain it in position, and allow dressings to be applied without disturbing it. . . . . .

It happens now and then that our attempts to save limbs, though successful, end in disappointment; the limb preserved being from some cause less useful than an artificial limb, and a source of discomfort to the owner. Such a misfortune may occur in consequence of an extensive destruction of integument so that a raw surface which nature has not sufficient resources to cover in is left, to the continued annoyance of the patient, who will sometimes ask to be relieved of the extremity which it has taken so much trouble to preserve. We might fairly consider the new proceeding of grafting a portion of epidermis upon the gap to be filled up as, in such cases, partaking of the nature of conservatism. Or this inutility may arise from malunion, the causes of which I need not here enter upon.

There is here a cast of a badly-united leg, which was almost useless, and the seat of constant pain. The patient would gladly have exchanged his burdensome limb for a wooden pin, but acting in the spirit of conservatism, although the word was not then used, I cut out a wedge from the projecting tibia, divided the fibula with cutting pliers, and set the bones straight. The result is seen in the fellow cast. This operation was performed more than twenty years ago; but I had an opportunity of seeing the patient a few days since, and he informed me that, although the leg operated upon is somewhat shorter than the other, he has never experienced the slightest inconvenience, and for these twenty years it has been a good serviceable limb to him.

The term conservative as employed and understood by its distinguished originator does not, as already indicated, entirely cover the tendency of modern operative Surgery to abstain from the use of the knife, and substitute other milder and safer proceedings. I shall venture, nevertheless, to include among these illustrations of the conservatism of modern operative Surgery some such examples of abstention from the knife, since the spirit which pervades them is absolutely identical with that of conservative Surgery.

There are few structures of the body which have been the field of more brilliant and daring operations than the arterial, whether these have been executed to stanch the flow of blood from a wounded vessel or for the cure of aneurismal disease. Such operations have been oftentimes as successful as they have been daring, but too often, also, they have been brilliant failures, followed by a fatal result; sometimes life has only been preserved at the expense of a limb. Much has already been done in modern times to diminish the number of such failures and to further the conservation of limbs by the employment of mechanical measures in the place of cutting operations. In carefully adjusted position, for instance, we have a ready means of modifying the force of the arterial stream. The mere elevation of a limb exercises considerable influence over its circulation; but other positions, such as extreme extension and flexion, either with or without elevation, may be so employed as to keep the blood stream under almost perfect control.

A young woman was admitted into University College Hospital, a good many years ago now, whilst I held the office of House-Surgeon under Liston in that institution, with a wound of the superficialis volæ artery, inflicted by the point of an oyster-knife. The injury had been done some days before her admission, repeated attacks of bleeding had occurred, and vain attempts had been made to secure the ends of the vessel in the wound; the hand was swollen and inflamed, and the wound in a sloughy condition. I had her arm raised very high upon pillows, and stretched out in the extended position by bandages to the hand, whilst irrigation with cold water was employed to the wound, which was uncovered. No bleeding recurred. At that time I believed that the elevation of the limb was the sole cause of the arrest of bleeding, but I am now inclined to think that the extended position of the arm was also not without some effect. . . . . .

My attention was first drawn to the effect of this position two years ago by one of the Surgeons of the Lariboisière, who informed me that he had ascertained by experiment that by extreme extension the force of the arterial circulation might be materially modified. I have myself experimented upon this position, and find that, in thin persons particularly, extreme extension, or, as it may be shortly called, "over-extension," of the elbow-joint enfeebles the pulse at the wrist, and where the elbow-joint admits of being so extended that the end of the humerus presses forward against the artery the pulse is entirely extinguished. Abduction of the shoulder-joint and over extension of the wrist aid this effect. In the lower extremity, if a hard cushion be placed under the buttock, and the hip and the knee-joints over-extended, the pulse at the ankle is also very greatly enfeebled. I have not employed this method in cases of actual bleeding; but although the position might be difficult to enforce, believe that it would be useful, at least as an auxiliary measure.

A French Surgeon has recently impugned the efficacy of flexion as a blood-stopping means. I have therefore had some experiments done at the Infirmary here, with a view to test the effect of this position upon the pulse at the wrist, and at the ankle.

These experiments were done at different times, and on several different individuals, by Dr. Page, our excellent House-Surgeon; and by myself separately, with the assistance of Mr. Kaye, my dresser, with the following results:—

A. *Upper Extremity.*—1. Forearm bent on arm by muscular action of the individual experimented on. In persons with considerable muscular development, pulse at the wrist entirely stopped.

2. Forearm bent on arm simply, with the hand flat on the shoulder. Pulse weak and indistinct, sometimes quite stopped; this rarely.

3. Forearm bent on arm, with hand pronated. Pulse more weakened, sometimes entirely stopped.

4. Forearm bent on arm, hand pronated and extended. Pulse usually quite stopped.

5. Forearm bent on arm, hand pronated, and bent at wrist. Pulse either almost imperceptible or quite stopped.

6. Forearm bent on arm, with a roll of lint or cambric pocket-handkerchief, rolled up and laid in bend of elbow. Pulse always stopped.

B. *Lower Extremity.*—1. Leg fixed on thigh. Pulse in posterior tibial artery much weakened.

2. Leg flexed on thigh, and high on abdomen. Pulse in posterior tibial stopped altogether almost invariably.

3. Leg flexed on thigh, with a roll of lint or cambric pocket-handkerchief laid in the bend of the knee. Pulse stopped in some cases, not always; but with flexion of thigh on abdomen also, pulse invariably stopped.

4. Thigh flexed on abdomen, the trunk bent forward. Pulse materially weakened.

From these experiments, as well as from those cases of actual bleeding, in which this method has been used, it may be fairly inferred that we possess, in over-flexion, a blood-controlling agent of considerable power, which can be applied on the shortest notice; which requires neither instruments nor apparatus other than can be obtained in the poorest cottage; which can be put in force by any one possessing neither special knowledge nor operative skill; which is not dangerous in itself; and which may be relied upon with certainty to restrain bleeding, at least temporarily, even when it may fail permanently to arrest it. The bleeding from a wounded artery is so striking a thing—so many circumstances concur to attract the eye and arrest the attention—the crimson blood flying in jets across the room, or welling from the wound; the death-like aspect of the bleeding man—his livid pallor and convulsive agitation, these are so appalling, the absolute danger is so great and imminent, that we do not wonder if the ordinary bystander is palsied by affright, and the Surgeon himself deeply impressed by the gravity of the situation. It is to such a scene that suddenly, and without preparation, he may be summoned, perhaps to some remote place, perhaps in the middle of the night. Without assistants, except the terror-stricken spectators who encumber the room; by a flickering light of the candle, a practised operator might hesitate to undertake the search after the wounded vessel.

If, then, at such a time the mere flexion of a joint will remove the danger, allay the tumultuous excitement, dissipate the apprehension and anxiety, and relieve the Surgeon from an embarrassing and perhaps doubtful operation, were it only temporarily, it is surely a valuable addition to our resources.

But when I find that in the upper extremity over-flexion may be relied upon as a permanently efficacious measure, enabling us, in wounds of the palmar arch for instance, to avoid a tedious and perhaps mischievous dissection in the palm, or the ligature of all the arteries of the forearm or of the brachial; when I recall to mind the controversies which have prevailed as to the best treatment of repeated and secondary hæmorrhages; the choice offered to us between a tedious, difficult, and uncertain dissection in the midst of an ill-conditioned wound, or among a huge collection of clots, in search of the bleeding orifices, and a serious operation to ligature the trunk, in the lower extremity at least—an uncertain, not always effectual, and sometimes dangerous, proceeding; when I read in the most recent systematic works on Surgery, that secondary hæmorrhage from the deep arteries of the leg is a sufficient reason for amputation, and remember that I have myself seen a person narrowly escape amputation of the hand in consequence of wound of the palmar arch, I cannot but think I am justified in offering to your consideration this method as an illustration of conservatism in Surgery. If you consider this account tedious and unnecessarily long, I must express my regret; but as this mode of staying the flow of blood from bleeding arteries is only just mentioned in the last edition of Mr. Erichsen's "Science and Art of Surgery," and not even alluded to in Mr. Holmes's—the most complete and popular systematic works on Surgery of the day—it seems that some account of my own experience of the effect of position might not be altogether uninteresting.

A more remarkable example of abstention from the knife is to be found in the pressure treatment of aneurism. Sir Wm. Fergusson remarks that when Hunter tied the superficial femoral for the cure of popliteal aneurism, he performed a great act of conservatism; but modern Surgery has acquired in the same direction results still more important and more beneficial to humanity; aneurism of nearly every artery in the body, including the carotid, the subclavian, the iliacs, and the aorta, having now been cured by pressure. The old or slow pressure method was an advance upon the ligature; but what I believe was first named by myself—the "rapid pressure treatment"—must be considered to be in some respects even a greater improvement upon the older plan. Having arranged to read a paper on this subject, it is not my intention now to enter into it; but here in Newcastle, where the method originated, it could not be passed over without mention.

The rapid pressure treatment may be considered but the natural development of the older method, and, like so many other triumphs of modern Surgery, owes its practicability to chloroform. Having been myself somewhat concerned in its introduction, it would not become me to speak too strongly in laudation of it.

I should rather leave to those who best know what dangers encompass him who is submitted to the knife and the ligature—the shock, the suppuration, the erysipelas, the pyæmia, the gangrene, and the secondary hæmorrhage—the appraisement of a measure which, after a few hours' sleep, leaves the awakened patient free from his disease, with no wound to heal, no further risk to run, and to say whether any Surgical proceeding ever more truly deserved the application of the old maxim—*Cito, tuto, et jucunde.*

III.—The Success of Modern Operative Surgery.

It is in one sense a matter of indifference to what part of operative Surgery I turn for illustrations of its success; they abound everywhere. They might be found in the subjects we have already treated; or I might take to choosing at random some special department, say the orthopædic, and adduce the wondrous metamorphoses produced by its agency in proof of my position—the variously twisted and useless feet opened out, straightened, and made serviceable; the withered bent limbs made strong and shapely; the hideously distorted trunks conjured into symmetry; transformations worked with a perfection, a facility, and an absence of pain to the patient which seem little short of miraculous when we look at the condition of this branch of our art some forty or fifty years ago. Transformations, too, not now confined to some special metropolitan Hospital, but which may be undertaken by any provincial Surgeon to overcome difficulties and enable him to complete the transformations, towards which the division of tendons is only the first step. Here, too, I might refer to an aspect of our art most interesting to study—the moral effect produced by raising a misshapen, halting creature to the condition of a straight and well-proportioned man—an aspect which brings mechanical art into a close and remarkable relation with the subtle and mysterious problems of psychology. I prefer, however, as more in consonance with my design, to take examples from fields which have been more generally cultivated, and for a longer period, by the great body of the Profession, and from operations which contain in themselves all the essentials of treatment independent of the assistance of the mechanist. The operation of cutting for the stone, for instance, furnishes an example of this description. There have always been individual operators who have have been remarkable for their success in cutting for the stone; thus twenty, twenty-five, thirty, as many as forty persons have been cut in succession by different Surgeons without a death; but such examples would not serve the purpose I have in view, which is to show the success of modern operative Surgery in this operation, not the skill of any individual. Let us take, then, the lithotomy operations performed at any provincial Hospital throughout a series of years and distributed among several different Surgeons—say, for instance, the Newcastle Infirmary. In this institution, between the years 1859 and 1869, both being included, lithotomy has been performed sixty-four times, and of this number two operations only have been followed by fatal results. These sixty-four operations occurred in different proportions in the practice of six different Surgeons, who, during the time stated, have held office at the Infirmary for longer or shorter periods. The ages of the patients varied from two and a half years up to seventy, both of these extremes being among the successful cases; twenty-nine were ten years of age or under ten; sixteen were upwards of forty years old. Of the two fatal cases one was thirty-eight years of age, the other fifty-two. The average time between the operation and the date of dismissal from the Infirmary was twenty-eight days. The operation performed was the ordinary lateral one, which, introduced by Cheselden and modified by Liston, is that, I believe, most usually practised by British Surgeons.

These cases, then, were not of an exceptional character; but in every way examples of the ordinary kind of cases which may be expected to occur in Hospital practice; they were not in an unusual proportion of the most favourable age; they were not all in the hand of one operator, who might be supposed possessed of unusual skill; nor did they come under treatment during one particular short period, when for some special reason it might be thought that a run of favourable cases might have occurred; and they were operated upon in a provincial Hospital, where we do not arrogate the possession of unusual skill or success. We may therefore fairly assume that the results give us at least an approximation to the average success which the operation of lithotomy had attained at the period of their occurrence.

The ordinary rate of mortality after this operation, as calculated from a large number of cases, not confined to recent years, is stated by Coulson and others to be about one in seven. Sir William Fergusson states that out of fifty patients under fifty years of age cut by him in the whole course of his experience, two died: this is above the average of success as given by Coulson for the same age, but it must be considered below the rate of success of the Newcastle Infirmary for the time stated, the operations at this Institution being on persons of all ages.

If, then, I am correct in putting forward these cases as representing an approximation to the average results of modern lithotomy, it must be conceded that they constitute good illustrations of modern operative Surgery.

It has already been stated that the operation performed was the ordinary lateral one, and I am not aware that there was any peculiarity in the way in which it was carried out by any of the operators; with the exception that in some of the operations on children, performed by myself, the stone was removed by the finger alone introduced into the bladder, and without the employment of forceps; nor in the after-treatment employed. The instruments used were of the simplest description—the usual laterally grooved staff, sharp-pointed lithotomy scalpel, and forceps.

The success of the modern operation of lithotomy may be attributed in part to this simplicity of the instrument used; in part to the greater gentleness with which in modern times we employ our tools, particularly the forceps, so that we avoid the pulling and hauling with both hands, the violent movements of instruments from side to side, which in former days were not unfrequently witnessed, and the consequent bruising of the neck of the bladder and other structures, proceedings fraught with dangers which I need not enumerate; and greatly also to the use of chloroform, by which the operation is robbed of

more than half its terrors; and thus patients are encouraged to seek relief from their pain at an earlier period than formerly, and whilst the urinary organs are still not seriously affected by disease.

The modern procedures for the relief of strangulated rupture, for the extraction of cataract, and of ovariotomy, will afford us equally notable examples for the success of the operative Surgery of the day.

By the modern operation for hernia, I mean especially the operation without opening the sac, perhaps the most satisfactory and successful proceeding in the whole range of Surgery, aiming at so splendid a result as the rescue of a life from imminent danger. The operation, when the sac is opened, is itself, much more successful in the present day than it was some thirty years ago, being usually put in practice after a much shorter period of strangulation, and followed by a more sensible and rational after-treatment; but the operation without opening the sac is, I believe, as absolutely certain of success as any proceeding can be. I can remember when the result of herniotomy was considered so doubtful that every device was had recourse to avoid it, from the injection of tobacco to placing the patient on his head, or trundling him down the street on a barrel; and I have heard a Physician of great repute condemn the proceeding altogether as dangerous and unnecessary, asserting that the strangulation might always be relieved by repeated doses of calomel.

It is not astonishing that the result was uncertain when we consider the mode of operation not unfrequently adopted in those days. After a long and dangerous period of strangulation, we had an external incision running the whole length of the hernial tumour, followed by a painfully tedious dissection, occupying sometimes the better part of an hour, layer by layer down to the sac; this reached, it was opened to an extent commensurate with the external incision, and its contents assiduously manipulated, probably by more than one pair of hands, to ascertain the condition of the bowel; the stricture was then divided, the knife being passed in dangerous proximity to the bowel, which occasionally has been wounded even by the best operators; and when the operation was over, the Surgeon was not satisfied until the maimed and bruised bowel had been further tortured by purgatives and coerced into unnatural action.

How different is the modern proceeding! A small cut less than two inches in length is made over the neck of the sac; a little dissection with the handle of the knife or the finger-nail reveals the edge of the ligamentous structure; a few fibres are divided; gentle pressure is made upon the sac, which may not even have been seen; the bowel slips up, and all is over. The whole business not occupying ten minutes, an opiate is given, and the Surgeon has no further anxiety about his patient.

I know it may be said that this method cannot always be adopted; and indeed, in looking over some recently published cases of herniotomy, I must acknowledge to have felt some surprise at the frequency with which the sac has been opened.

It has fallen to my lot, as indeed to that of most operators, to operate in such cases pretty frequently; and for the last fifteen years I have rarely found it necessary to open the sac. Unless, indeed, there is some special reason for doing this, such as the great length of time during which the rupture has been down, the manifest pressure of a large mass of omentum, or indubitable signs of change in the bowel, emphysema, putrid smell, or the like, I invariably attempt the reduction without opening the sac; and, according to my own experience, the test of the propriety of the proceeding is in its practicability, for I have never in my own practice known a fatal result where the sac was not opened.

By the modern operation for the extraction of cataract, I mean the method—by whatever special name we call it, whether scoop-extraction, or Schift's operation, or modified flap extraction; whether the iris is touched before or after the extraction of the lens, immediately before or some time before, which consists essentially in a comparatively small incision through the cornea, the removal of a portion of the iris and extraction of the cataractous lens by gentle manipulation, aided by spoon, curette, vectis, or other similar instrument, diversely employed; for I take it the same principle pervades all these methods, however they may differ in minute details.

I claim for these modern operations, although each may be more particularly applicable in special cases, a greater and more uniform success than belonged to the old flap-operation.

I acknowledge that nothing can be more brilliant and striking in its performance, nor more excellent in its result, than a perfectly successful flap-operation after the old mode. After such a proceeding, when entirely successful, there is a scarcely perceptible cicatrix, a transparent cornea, an unmutilated iris, an undisplaced, round, central, clear, black pupil, and consequently sight as perfect as is possible after the removal of the lens. But then, how frequently does this perfect and complete result ensue? We must confess but rarely. How often, on the contrary, are the hopes of the operator disappointed even when all goes well at the operation? How often do we find that the edges of the wound become separated, that part of the iris protrudes, that the healing is delayed, and that ultimately there is a partially closed or distorted pupil, with broad cicatrix and more or less imperfect sight?

In the modern operation, although the pupil is necessarily somewhat misshapen, we can yet reckon with considerable if not absolute certainty upon a result so far successful as to give good useful sight. Although, then, the old operation in exceptional cases gave a result which left nothing to be desired, the new operation gives a more universal and assured success.

I need not detain you by any lengthy reasoning to show the success of "ovariotomy" in recent times. You know that from being looked upon as one of the most fatal performances a Surgeon could undertake; from being stigmatised by some of the greatest men as a frightful butchery, it has risen to take its place as a well-recognised proceeding—more successful than some older and long established operations. It is, indeed, emphatically one of the most brilliant examples of the success of modern operative Surgery.

These three operations do not, at first, appear to bear any close resemblance to each other, being undertaken for very different purposes, and one taking place in a little world as it were apart from the rest of the body; yet a brief examination will show that they possess some features in common; and although each may depend for its success upon some particular proceeding more or less special to itself, will enable us to discern certain principles common to all three greatly influencing their favourable termination. Thus in all three operations, a serous cavity containing important structures is more or less involved, and each may fail by reason of inflammatory action destroying or impairing the functions of these structures; or as in ovariotomy and hernia, by reason of other more serious consequences, to which procedures affecting such regions are more particularly liable.

The operation, without opening the sac, manifestly owes its success mainly to the fact that the peritoneum is not opened, and to the consequent exclusion of air, blood, or other contaminating fluids from the abdominal cavity; but the small size of the external incision as compared with the importance of the structures actually divided, and the still greater importance of those indirectly affected, is also not without an important influence, as well as the trifling amount of bleeding and consequent absence of blood within the external wound.

The modern modes of extracting cataract are less frequently followed by unfavourable results, mainly because the removal of the iris prevents prolapse of that structure between the lips of the wound and consequent delay in healing, morbid changes in the cornea, and contraction of the pupil; but the limited size of the corneal wound prevents loss of vitreous humour, excludes air from the anterior chamber, assists generally in preserving the integrity of the eye, and admits of more rapid healing; whilst the entrance of blood into the chamber is always an accident to be deplored, and sometimes injuriously affects the result of the operation. And in ovariotomy, although special circumstances affecting either the tumour or the patient exercise undoubtedly great influence over the result, nevertheless I conceive that this remarkable operation, which does not really require great operative skill or extraordinary manual dexterity, and which not unfrequently succeeds under apparently unfavourable conditions, as when adhesions exist, or when the patient is reduced to a condition of extreme weakness, is most likely to have a favourable termination where the wound in the abdominal parietes is small, four inches or under in length; when the time occupied is comparatively short; where the abdominal cavity and its contents have been little exposed to the air; and where, in particular, neither blood nor other fluids have entered in any quantity, or remain in the abdominal cavity. Ligatures, whose material seems almost a matter of indifference—wire, catgut, or hemp—may remain with impunity, but not blood, at least in any quantity.

Here, then, are certain common principles greatly affecting the success of each of these different proceedings. 1. The limitation of the external wound, as compared either with the

magnitude of the part to be removed, or the importance of the deeper structures involved, or the greatness of the result to be obtained, or, in other words, the approximation of the operation to a subcutaneous wound. Herniotomy without opening the sac, and the new operation for cataract, may be really regarded as equivalent to subcutaneous operations; whilst the small opening in the abdominal wall, through which the enormous mass of disease is drawn, really gives to ovariotomy a certain approximation to that form of proceeding. 2. The exclusion of air from the wound itself, or from the serous cavities involved. 3. And last, but not least important, the exclusion of blood from the wound itself, or from the cavities involved. Although these principles may be considered specially important in such cases as these, where a serous cavity is implicated, we have constant opportunities of observing their importance in operations generally. Indeed, it is but natural to infer that the principles which, carefully carried out, lead to the success of such an operation as ovariotomy, should also powerfully affect the success of proceedings upon less important structures.

In the excision of joints as now performed, as well as in the extirpation of growths from the bones of the face, we have examples of the limitation of external incisions. This principle, quite distinct from conservatism, not only favours rapid healing and diminishes deformity, but, also, by covering in raw surfaces more effectually and permanently, diminishes the risk of entrance of air into wounds.

Amputation by anterior flap, though not an example of the limitation of incision, shows the good effect of the complete covering in of raw surfaces. There is a cast here of another stump left after amputation of the knee-joint, where a posterior flap was formed. The flap was amply sufficient to cover the bone at the time; but, primary union not taking place, the flap gradually slid down, leaving a raw surface uncovered. Healing was long delayed, and the patient necessarily exposed to many risks which I need not enumerate.

The importance of the exclusion of blood from wounds left by operation can hardly be overrated. Every amputation of a limb, or removal of a tumour or diseased breast, affords an example of the impossibility of effecting rapid union where blood or bloody serum is allowed to collect between flaps or in the cavity of a wound; and the danger of septicæmia from such a cause in the early days of an operation will be recognised by every one. The application of torsion to bleeding arteries will greatly assist us in carrying out this principle; and the exclusion of air has been considered a matter of such importance, that a variety of means have been employed to effect it, which I can only allude to here, such as the water-bath used in Berlin and the *appareil pneumatique* at the Hôtel-Dieu. But, without employing any such special apparatus, by the management of our preliminary incisions, and by methods of dressing, with or without antiseptics, much may be done to effect this important end.—*From the Address in Surgery, delivered before the Annual Meeting at Newcastle-upon-Tyne, by George Y. Heath, M.B., Surgeon to the Infirmary, Newcastle-upon-Tyne.*

THE SEWAGE QUESTION.

SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. III.

BANBURY SEWAGE FARM.

THE sewage farm is about one mile east of the town of Banbury. It consists of about 136 acres of a sandy clay soil, not very porous; and about forty-eight acres are under Italian rye grass, and the rest is pasture.

The population of Banbury is between 11,000 and 12,000, and the sewage amounts to about 300,000 gallons a day. It flows by gravitation from the town to the tanks of the old sewage works, where it settles for a time, the mud and scum being removed from it and mixed with street sweepings and other refuse, and sold in a solid state for manure. The liquid portion is lifted by steam power and conveyed to the head of the sewage farm, which is rather more than a mile off, and about twenty-one feet above the level of the tanks. It then runs by carriers over the ground, and finally into the river Cherwell, which is close to the lower part of the farm.

At the time of our visit, in the month of April last, the ground was sodden with sewage, and the side ditches were full of decomposing sewage, the smell from which was very offensive. There is only one house near the farm, and that is a little beerhouse called the Bowling Green, the landlady of which said that the smell from the farm was sometimes most sickening. We took a sample of the sewage at the head of the farm, and another from the effluent channel as it ran from the subsoil drain into the culvert which passes under the railway to the river Cherwell, and the following are the results of the analyses:—

Constituents per gallon.	Raw sewage.	Effluent water.
	Grains.	Grains.
Solid matter in solution . .	48·87	39·73
Chloride of sodium . .	8·94	8·46
Organic matter . . .	16·49	12·21
Ammonia	3·81	0·48
Do. organic . .	0·28	0·05
Nitrogen as nitrates, &c. .	0·00	0·63
Oxygen required to oxydise	1·42	0·83
Matters in suspension . .	3·27	0·38
Organic matter . . .	1·86	0·13
Mineral ditto . . .	1·41	0·25

A large portion of sewage was passing from the side ditches of the irrigated ground into the water course which flowed towards the river, and this was much worse than the above, which was from the subsoil drain.

Five thousand pounds have been borrowed to make the ground fit for irrigation, and a rental of £4 10s. an acre is paid for the land. Last year the returns from sale of crops, &c., was £160 less than expenses and interest of money.

WARWICK SEWAGE FARM.

THIS farm was visited in the month of April last. It is situated about one mile from the town, and consists of about 102 acres of stiff clay land under cultivation with Italian rye grass. The population of Warwick is about 11,000, and the sewage amounts to about 600,000 gallons a day. It runs by gravitation from the town to the subsiding tanks, where the suspended matters are in great part removed from it, and it is then pumped to the head of the farm, which is about fifty feet above the tanks.

The farm was in a sad plight at the time of our visit, for the winter frost had killed the grass over large portions of the farm, and the sewage was running over the ground in a very offensive state.

Samples of the sewage were taken at the entrance to the farm and at its exit from it; and the following are the results of the analysis of each sample:—

Constituents per gallon.	Raw sewage.	Effluent water.
	Grains.	Grains.
Solid matter in solution . .	47·21	52·63
Chloride of sodium . .	11·04	9·12
Organic matter . . .	12·95	7·42
Ammonia	2·20	0·52
Ditto organic . . .	0·14	0·03
Nitrogen as nitrates, &c. .	—	0·10
Oxygen required to oxydise	0·86	0·48
Matters in suspension . .	24·67	0·26
Organic matter . . .	11·87	0·13
Mineral ditto . . .	12·80	0·13

The farm has been in hand about two years, and it cost about £12,000 for plant and for laying it out, and a rent is paid of £3 an acre, and £1 for taxes, making a total of £4 per annum per acre; and last year the produce just paid the working expenses of the farm, without interest of money or cost of superintendance.

WEDNESDAY, SEPTEMBER 7, 1870.

LORD DERBY ON PREVENTIBLE DISEASE.

Those who have the cause of medical science at heart must always rejoice when any extra-professional person of eminence can be found to interest himself intensely in aught that pertains to the physical welfare of the people at large. Not that we have not plenty of examples of noblemen and gentlemen of high rank taking up with some new-fangled medical doctrine, such as homœopathy, or mesmerism, or spiritualism. Enough and to spare of these we have. It is, indeed, scarcely to be expected that persons who, like hereditary monarchs, never have the slightest inducement to study any subject seriously, should be always more or less amateurs in their pursuits in life. In Lord Derby we have a man of a very different calibre. His grasp of scientific questions is always profound, and his deductions logical and instructive. Though not a member of the medical profession, we are convinced that a profound mathematician and man of science as he is, has found it necessary, in these days of positive science, to make the study of biology and pathology part of his occupation in life. And, as he is in that sublime position that no one can believe or assert that any of his medical opinions are delivered for the sake of gaining public applause and emoluments thereby, all that falls from his lips on the subject of hygiene must prove fraught with interest to the earnest physician or medical enquirer.

In an eastern suburb of one of our most unhealthy commercial cities, Liverpool, among fetid brick-fields and other unlovely accompaniments of modern money-getting, a new hospital has been inaugurated by Lord Derby, on which occasion words to the following effect fell from him. At the very outset of his speech he mentions the conflicting opinions now held as to the question whether hospitals should be erected by voluntary subscriptions, or by each city or authorities of each parish. It is fairly maintainable as a proposition that the relief of sickness stands on precisely the same footing as the relief from destitution, and that an hospital rate would not be less justifiable than a poor-rate or an education rate, and probably this may ere long be thought generally. In the meantime there is much, says the speaker, to be said in favour of leaving hospitals to the care of private charity. But, even at the present time, says Lord Derby, with great truth, many of us are far too apt, even in these days of supposed sanitary knowledge, to talk and think of disease as if it were a calamity inflicted on us by the direct act of a higher power; and, as if all we could do in regard to it, were to observe some well-known public precautions, and then to wait, and only hope to mitigate its violence in individual cases. There is an amount of truth contained in this expression of the speaker which is quite incalculable. He adds that he thinks that he will not be accused of exaggeration when he states that if we could deduct from the actual amount of disease at any one time existing in the country, all that can be clearly and unmistakeably traced to human and preventible causes, we would have a comparatively small amount to deal with. This is, of course, a necessary deduction from the well-known fact that in many large towns, such as Glasgow, and several others, the death-rate is higher than thirty per thousand, whilst in healthy rural districts it is not much more than half that rate. Consumption, rickets, and scrofula haunt our large cities, and cut off children and young adults in a dreadful manner. No figures of statistics can give us the immensely large number of damaged existences which are the consequences of our present system of living in large cities. What statistics can tell of the ruined health of the poor work-people confined from morning to night in some sedentary occupation in dirty towns, or of the numbers of persons who fall victims to great fatigue conjoined with scanty nourishment in all our hives of industry?

Look at questions such as this! Contemplate the vast mass of indigence, for instance, congregated even in wealthy London: 123,000 paupers in the month of August, 1870. The more you reflect over such gigantic poverty and such detestable circumstances, says Lord Derby, the more easily will any man of reason accept the consoling conclusion that in sanitary matters at least the world's future need not be like the past; that for the worst of the material evils which beset us, the cause is not in the arrangements of nature, but in ourselves. This is the age of great cities. It seems impossible to carry on the complicated business of modern society without such gigantic cities. This being the case, we must accept the fact, and endeavour to do our best to make town life as healthy, both physically and morally, as country life. Broad streets, good drainage, plenty of open spaces, plenty of light and air, are, of course, if possible, to be secured. Good and cleanly houses for the poorest classes; baths and wash-houses; fields for open-air exercise, and places of artistic amusement for the leisure hours of the citizen, are all required. Unless we try to accomplish such aims, much of our boasted civilisation is but an empty sounding lie. For, after all, is it not evidently the bounden duty of truly civilised states to see that the happiness of every person in the community is up to a certain standard. Who with any knowledge of matters as they exist

at present can feel content with human science? As Lord Derby says with his usual profundity, "All the true wealth of a state is not shown in the lists of its exports and imports, nor in a vast revenue easily raised, nor in its enormous yearly savings, of which our statistical writers boast." (Porter's *Progress of the Nation* is a good example of the empty glorification referred to by the speaker.) "All these things are excellent in their way; but excellent though they may be, they are means, not ends, and the end of them all is that we should have living on this English soil a population not squalid with dirt, nor decimated by disease, but healthy in body and mind, trained for all needful purposes, whether of peace or war, living in houses which make self-respect possible, and attached to a country which has done its duty towards them."

We are much mistaken if the concluding sentences of this speech will not be remembered as among the very best utterances ever made by that accomplished scholar and gentleman. We have often heard it said that it requires the highest of all intellects to sympathise in the sufferings of others, and this truth is well shown forth in this touching appeal to the British nation to be mindful of the amount of poverty and preventible disease weighing us down in the midst of all our progress in other directions. It is easy to see traces of the philosophy which guides the illustrious speaker in his utterances. No transcendentalist he. No half and half believer in experience as the only road to knowledge. No Kantist, nor Hegelian, nor disciple of Cousin, could speak as Lord Derby does. Positive science is evidently his guiding star. He reverences all that is attainable, and hence knows how to sympathise with the aspirations of the great physicians and medical men of all countries. A thorough political economist and enlightened follower in the footsteps of Ricardo, James, and J. S. Mill, we are proud to know that this country possesses such statesmen as he. Earnest, thoughtful, and without a shade of frivolity, he sets a bright example of steadfast faith in better times to those unscientific drivellers who deny the power of science to effect any amelioration in the condition of our race. It is no time for such idle talk when France is being overwhelmed in consequence of its scepticism in the wisdom of any of its former able statesmen. With a Gladstone and a Derby, we may be proud of possessing the ablest and most earnest politicians in Europe at the present moment. Nor do we fear for the future of public health questions when we have such eloquent advocates to plead our cause as the Earl of Derby.

THE IRISH LICENSING CORPORATIONS.

The fact which our analysis of Sir John Gray's return elicited last week—that the "College and Hall" exercise all but a monopoly of the qualifying powers in England, and that the University contingent is little more than one twentieth of the whole—applies in no respect to Ireland, where medical licensing is exercised by five licensing bodies under the influence of a very active and, we presume, useful competition. Here the whole condition is changed, and the Universities claim a much larger share in the duties and emoluments of licensing than in England. The reason of this fact seems to us to be obvious. In England the purpose of the two senior Universities is not in the education of professional men at all; it is devoted to the conferring on the sons of the gentry that patent of education which is felt to be a necessity of social position. Therefore, their teaching is almost altogether applied to arts and literature, and not to the making of doctors, engineers, or even to any great number of clergymen.

In Ireland, on the other hand, University education is usually taken as a means to the higher walks of professional life, and, therefore, education in special sciences goes hand in hand with Arts instruction, and are as much, or more, a means of livelihood of the Universities than literary education.

Thus it is that we find a much more equal level occupied by the medical licensing bodies. The Royal College of Surgeons has conferred, in the five years ending 1869, an average of ninety-five surgical diplomas each year, and admitted eight fellows to its Corporation. It seems to maintain, and even improve, its position in spite of the competition to which it has been subjected, for the licenses granted for the last two years are in excess of those of any of the previous three.

Of its annual influx of licentiates, only a very small proportion (eight) seek its midwifery diploma, while a still smaller number have for the last three years gone forward to its fellowship. The causes of these two regrettable facts may not be comprehended by our readers, but they are none the less obvious.

The medical qualification of the licentiates of the College of Surgeons is usually taken, not from the Universities, but from the Colleges of Physicians of Dublin or Edinburgh; and, as midwifery is likely to be regarded rather as a phase of medicine than of surgery, and the College of Physicians in Ireland gives the qualification to its own licentiates for an extra fee of five shillings, while the College of Surgeons charges a guinea, it is not wonderful that students prefer to combine that branch of their education (if they take it at all) with medicine rather than with surgery.

The College of Physicians of Ireland is so close to the College of Surgeons in its annual grant of licences that the dependence of the Colleges on each other may fairly be, to a certain extent, assumed. It admitted in the five years an average of eighty-one licentiates in medicine in each year, and on sixty-four of them conferred its midwifery diploma, and it may thus be roughly calculated that of the ninety-five men qualified by the College of Surgeons, eighty take their second degree in the College of Physicians, and fifteen go to Edinburgh or Glasgow.

These figures ought to serve a good purpose by showing the Colleges how close their connexion naturally is, and how wise a step it would be that that connexion should be drawn closer together. It is greatly to be regretted, now that it is shown, that the diplomas of each College are almost always sought for by the same candidate that monetary difficulties should oblige that candidate to undergo two examinations instead of one, and should imperil the prosperity of each Corporation by enforcing an artificial separation.

This argument would seem to apply most forcibly to the College of Physicians, because that body is not in as good a position to maintain its position without the patronage of the College of Surgeons as is the College of Surgeons to sustain its supremacy without aid from the College of Physicians.

In the present state of medico-educational feeling, surgery, undoubtedly, takes rank with the general practitioner as the more important branch, and candidates will always look first for their surgical degree, and afterwards for the most convenient medical qualification. Moreover, the College of Surgeons has a choice of Corporations, from which its *alumni* may take their medical degree, while the College of Physicians, having no reasonable expectation of Scotch or English patronage, have, in Ireland, no other source of supply than the College of Surgeons.

The College of Physicians has, however, no occasion for despair in the contemplation of the figures before us; for, it has established a substantial increase in the demand for

its licenses within the last five years. In 1865 it gave only sixty-six licenses in medicine, and forty-seven in midwifery, while in 1868 it conferred respectively a hundred, and seventy-six.

The University of Dublin labours, of course, under the competitive disadvantage of seeing the demand for its medical and surgical degrees clogged by the necessity for a full curriculum in Arts. Nevertheless, under the energetic administration of its Medical Registrar, the Reverend Dr. Haughton, it has been placed, as regards medical qualifications, in the foremost rank amongst Universities which insist on a complete Arts curriculum.

The supremacy of Trinity College, in this respect, may probably owe something to the recent disestablishment of the Irish Church, for the activity which has, hitherto, reigned in its Divinity School has been diverted, probably in anticipation of reduced revenues from clerical sources, to the Medical Faculty. To whatever cause the amelioration may be attributed, it appears that the University has made consecutive and rapid advances in the numbers of medical graduates within the last five years. It commenced in 1865 with nineteen Baccalaurreates in medicine and eleven Masterships in surgery; and in 1869 these numbers had increased, *equo passu*, to forty-one and nineteen respectively, an advance of exactly 100 per cent.

The University of Dublin also evinces a very laudable desire to maintain the educational rank of its graduates, for it has almost altogether laid aside the licences in medicine and surgery, which were set up some years ago for the purpose of competing with the Royal College of Surgeons, and for which only a nominal qualification in Arts was demanded. On the whole, the University of Dublin occupies, in matters medical, a very creditable position, and seems quite able by its own exertions, and its well-earned prestige, to retain the confidence of the Profession, in spite of the blandishments which the Queen's University exerts to attract students.

The Queen's University in Ireland, although it has not thriven at the expense of Trinity College, occupies a very respectable rank amongst Irish Licensing Bodies, and has effected a very unequivocal progress within the last five years, albeit it, as yet, does not at all realise the grandeur of its conception as the National University. Its *piece de resistance* is the M.D., of which it granted thirty-one in 1865, and fifty-one in 1869. Granting in these years respectively twenty-four and thirty-three Masterships in surgery, an increase of nearly 30 per cent. in its total of medical graduation. When it is remembered that the University M.B. costs £99 4s., the success of a £5 licence will be easily understood; yet it is but just to say that the Queen's University has not climbed into the degree of success which it has attained by depreciation of their curriculum, or a make-believe examination.

The last of the Irish Licensing Bodies is the Apothecaries' Company; and the melancholy condition of starvation in which that Corporation exists, *quoad* its licensing powers, ought to be taken to heart by all qualifying bodies. It will be recollected that we pointed last week to the London Apothecaries' Company as enjoying the confidence, and receiving the adhesion of, nearly seven-tenths of the entire number of English licentiates.

The Dublin Apothecaries' Company forgot its duties and privileges as *the* Pharmaceutical Corporation of Ireland, and took to the manufacture of doctors. With what result? It put its seal last year on twenty licentiates in medicine, which, at 10s. each, produced it a gross income from this source of £10.

And this while the state of Pharmacy in Ireland was a bye-word, and even sleepy governments were moved by shame to seek a remedy. Already has the Dublin Apothecaries' Company ceased, as an examining or qualifying body, to exist, and if our anticipations are verified, soon will it cease to exercise any power even in the regulation of Pharmacy in Ireland.

Notes on Current Topics.

About the War and Wounded.

The startling intelligence of the last few days may seem to throw some of the expressions in the following paragraphs behind date, but as made from time during the week, we have not thought it advisable to revise the phraseology.

The readers of newspapers who seem to labour under a morbid excitement, that some proprietors were stimulating by most reprehensible practices, have surely this week had enough of carnage. The appetite for the horrible too has been further pandered to by estimates of the slain. Thus, by one journal we are told that the German losses reach 200,000, and though this is the highest number we have seen quoted, we know they must have been enormous, and it is significant that no official publications of the numbers are made. But, whatever the totals, we know that the sufferings of the wounded are beyond ordinary comprehension, and our predictions that pestilence would follow in the wake of the armies seem already to be realised. Fever, pyæmia, dysentery are known to be now prevalent, and there are whispers of cholera—a disease which will terrify troops who have no fear of the mitrailleuse, and will demoralize armies more than defeat. The time, then, draws nigh when disease will asert its influence as greater than that of the sword, and when the sick may be more numerous than the wounded.

We have already pleaded for contributions in kind rather than in money. Of course, those who cannot give time and trouble, may assist by giving money; but what will be most needed we have already specified, and thousands of ladies can find material and time to make bandages, charpie, and so on. Our Profession can vastly help by teaching kind-hearted patients how to make them. Plenty only need to be told how to roll up a bandage, and the lengths and widths most useful to set them to work with a will. Last week we informed a lady that calico, flannel, &c., torn in strips of 1½ inches to 3 inches, and any proportionate, intermediate widths, and of three, four, six, or more yards length, would be particularly useful, when the material was at once procured, and at our second visit, we were required to show how to roll up one bandage. The result of this was, that a most useful packet has already reached the Seat of War.

Again, we were asked about charpie, and explained that very old soft, but scrupulously clean *linen*, cut into squares of two inches or a little more, could easily be picked to pieces with the fingers—every thread being separated—and that the resulting mass was highly prized as an application to wounds by French surgeons. Thereupon, a whole family set to work, the children kept at the task for days, and we have had the pleasure of sending a large package to the Palais de l'Industrie, where Count Flavigny's committee sits *en permanence*.

The ladies who so earnestly made bandages, charpie, &c., having disposed of all the material in their houses, requested the gentlemen of their households to hand to them instead of a society, the pecuniary contributions they intended for the wounded, that its value might be enhanced by their labour. Armed with this money and the thrift and the foresight of their sex, they requested their

drapers to sell the calico, flannel, linen, &c., required, at a reduced price for this purpose. The drapers at once agreed to let them have what they required at cost price, and so they had so much the more material on which to bestow their work for the wounded. By the time our patients had finished the work they had become so interested in it, that they next proceeded to enlist their friends, giving each a lesson; so that others are now busy in the same way, and who knows how far the good work may spread?

Every medical man has it in his power to instruct some patient, and by so doing, may do more than by soliciting contributions of money. This is the way in which our Profession may best help the wounded.

We may now give an example of how the leaves of human kindness will spread. On the invitation of one of those we had instructed in rolling bandages, we went for a visit with a family from Saturday to Monday. The Saturday afternoon was passed in the enjoyment of the fresh country air and lovely scenery. On Sunday morning, however, the weather being less propitious, an immense roll of calico was produced with the remark "better day," "better deed," it was proposed that the invalids who could not go to church should spend their time in making bandages. The result was, that all preferred the latter employment, and we had the option of walking to church alone, or joining in the work. We chose to work for the wounded, and, in a few minutes, every one of us were hard at it. We worked with a will, so that on Monday morning a large package of well made bandages was despatched to Paris.

Dr. Russell bears testimony to the admirable manner in which the German *krankenträger* (bearers of the sick) carry on their arduous duties. The moment the fire slackens in any part of the field, they proceed on their errand of mercy and carry the wounded to the waggon. He incidentally alludes, too, to one of the most terrible tortures of war—thirst. "Water—water—for pity's sake, give me some water," was a cry that reached him wherever he went on one hot day; and an officer accepted from him, as better than champagne, some of the dirtiest water he ever saw.

The tortures that must be endured from thirst by these poor fellows, left, as so many have been, for whole days without help, is fearful to contemplate, and may induce a reverse of the sentence passed by some writers, that only skilled attendants are of any use.

Besides those left on the field, many are speedily conveyed to the nearest villages. After a battle, it is necessary to improvise hospitals in the speediest manner. For transport, every hay cart or farm waggon is pressed into the service of mercy; doctors are overburdened with work both on the field, on the route, and in the village hospitals. Priests and sisters of mercy of all orders lend willing service, the former often walking beside the waggon or cart in the capacity of driver, the latter discharging all the duties of nurses and domestic servants combined. The picture of all these mangled human forms coming in every kind of rough, jolting conveyance is too painful to dwell upon. It is only alleviated by the devotion of the men and women who strive to assuage the sorrows of war—the medical profession and its best assistants, volunteer nurses.

A correspondent wishes each soldier to be provided with a piece of lead foil, an india-rubber ball, and a ring of the same material, which, he thinks, with a couple of pieces of wood to be frequently found on the field, would enable him to staunch a wound.

A German correspondent, who speaks of all the towns and villages near him as crowded with wounded, estimates the losses of Prussia at 40,000 killed, another 40,000 wounded, in addition to very many thousands of men prostrate with disease, such as dysentery and fever. Well may it be asked, "Who can rejoice over such victories?"

Who can help regretting the allegations that have been made about firing on the ambulances? We do not place much reliance on the statements made in German despatches. We do not believe the French are so uncivilized. Mistakes may have occurred, and the question of a more distinctive badge is very properly revived. The idea of the bright yellow uniform—one not used by any European army, having long been relinquished by Spain—has, at least, the merit of rendering mistakes less likely to occur. It would, perhaps, be well for something of the kind to be done; but, meantime, every ambulance ought to carry *large* white flags with the red cross. The French assert that the Germans hoisted the neutral flag to protect their ammunition waggons. If this be true, the act deserves the execration of all Europe as likely to destroy the most successful effort yet made to alleviate the horrors of war. A nation guilty of such a trick should find itself under the ban of all others.

The question of allowing the wounded to pass through neutral territory has been spoken of by some of our contemporaries in a very flippant way. No doubt for the wounded, in some cases, this would be a great boon; but the Geneva Convention was not designed to be turned into a weapon, and no General in front of an equal foe would suffer such transit, for the simple reason that by so doing he would set free other lines of railway by which his enemy's army might be fed or re-inforced.

We are very glad to announce that our advice has been taken, and that Dr. Gordon, C.B., Deputy Inspector-General, than whom no one is more capable, has been accredited to the French army to report on the field hospitals and other matters. He is to be assisted by Surgeon-Major Wyatt, of the Guards. Professor Parkes, of Netley, will, we understand, proceed to the German army. We should be glad to see a much more liberal adoption of our suggestions. Drs. Gordon and Parkes will do all that can be accomplished by two men; but there is an inexhaustible field for acquiring military surgical expeperience, and we have hundreds of army surgeons who sadly need, and would rejoice to acquire, such practice. It is losing a grand occasion, one we may hope will not return, for our army surgeons to be at home learning nothing. If ourselves involved in war in this generation, who can calculate the gain to our wounded of such experience as that now being lost!

Our Paris correspondent has more than once alluded to the defective organisation in France, and the subjection of the medical to the *Intendance* department. This seems to be the reason why hundreds of men are now waiting in idleness instead of being at the front. Is it not grie-

vous, when thousands of wounded are dying for want of professional aid, that as cursed a system of Red Tape as England's own is keeping the surgeons from the patients they long to relieve ?

We hope our recommendation to send out foods in concentrated forms will be adopted extensively. The sick as well as the wounded need these, and they can be given where the doctors are not present. Liebig's extract of meat is one of the most useful articles. Another is Newnham's condensed milk. We have been trying this last article lately, and find it fully equal to the promises held out. We have no doubt Messrs. Crosse and Blackwell, the London agents, would supply it to the committees at a very reasonable price, and no medical man need be told the value of milk. A full supply of it would save many lives. We are informed that, on the recommendation of a friend of ours, the French Government has ordered a supply. Paris would do well to lay in a large store instead of the milch cows, which will require feeding. Again, we should think that our great manufacturers of preserved soups and meat essences of all kinds would supply the committees, who will send out goods instead of money at very low rates. Another invaluable thing—so much more highly appreciated abroad than among ourselves—is chocolate. The nutrient power of chocolate is very useful, and do not foreigners—above all, Frenchmen—often make a meal of a stick of it ? Such provisions as these will be of greater use than surgical appliances, which may remain useless when needed from the absence of surgeons.

The newspapers have published many extracts from letters sent to the committees, and also many letters from their own correspondents, containing important medical facts. One letter indignantly denies the assertion that personal help is not needed, and describes heart-rending scenes. He also declares that the French wounded are not so well attended as the Prussians. At St. Privat he did not see a wounded Prussian without a mattrass and a blanket ; but on going into the French hospital, he found everyone with nothing to cover him but his own great coat, and nothing to lie on but straw. Another letter tells us that at Pont-à-Mousson, the lady nurses had to sleep on straw in the open air. From many sources, too, we learn of fearful distress among the inhabitants of the war-stricken districts. Famine and pestilence usually follow war, and we may expect that Europe will suffer from all three scourges.

We have spoken of the Committees. The work of all deserves our sympathies. The National Society is the largest one, and has done, of course, more than the others. Col. Lindsay is chairman. It has sent out some forty surgeons, and much material. It is in relation with the National Societies of the Continent, and its help is afforded to both sides alike. The German Aid Society in this country seems to have flourished abundantly and requires no good word from us, The French do not seem to do so well. We observe they have two or three independent Committees. Could they not effect a union ? *L'Union fait la force.* The French have much to learn in the way of organising as the English understand it, and when they have learned it they will find more abundant help from English warm hearts. *Verbum sapientibus satis est.*

One of the very best things yet accomplished by the Committees is, the establishment of an International Field Hospital at Bingen. Dr. Thudichum is to have the charge of it, and Mr. Simon will give him his personal assistance. The Medical Officer of the Privy Council may here reap real laurels, and forget his blunders about Medical Reform, The hospital is to have 200 beds. The German Aid Society supplied the tents and bedding, the German Government gives the rations, and the English National Society provides the other requisites. We hope great things from the hospital which is on the neutral territory of Luxembourg.

Another happy instance of union is seen in the co-operation of the French and American Societies in Paris with the English. This co-operation is adding greatly to the influence and usefulness of all.

The wounded fill many towns in Germany where they have been removed as stated in our last issue. Some were obliged to be left in the streets, so fast did they come in, and this too without shelter. In one case 400 peasant waggons arriving together, the wounded in them who had been travelling two days had to be left all night in the vehicles. Still, great efforts are being made at Hanover, Cologne, Bonn, Dusseldorf, Mainz, Munich, Berlin, and, in fact, throughout Germany. The palaces of royal and noble families, and the houses of others are being rapidly transformed into hospitals, and the proprietors are, many of them, busy with sewing-machines, and, in other ways, providing what is needful.

Medicine and the War.

The *Birmingham Post* says that, in consequence of the war, there has been a great rise in the price of surgical instruments and of certain medicines. Quinine and chloroform are fast going up in value. A new sedative remedy—chloral—of which there are only moderate quantities available, is becoming scarce ; one of the largest wholesale houses in England considered itself quite fortunate the other day in being able to get about £30 worth of it. The same difficulty occurs with regard to surgical instruments. The trade is a small one, with no power of quick expansion, and the stocks being exhausted, instruments cannot be got. Of artery forceps, for example, we are told, there is not a pair to be had in Sheffield, and the same remark applies to other implements necessary to army surgeons. Indeed, we hear that in order to make up supplies required for use in France and Germany, even the pawnbrokers' shops have had to be visited.

Training for Slaughter.

The great object of both French and Prussians at the present time is to obtain recruits. We are informed a fifth of the men being quickly trained for slaughter, are unfit either by constitution or in physical strength to stand against long and fatiguing marches, or hold out against the vicissitudes of the battle-field. Some of the best soldiers being, "where the wicked cease from troubling and the weary are at rest," those who take their place are poor substitutes, so that we must not expect them to compete with professional soldiers in the hour of strife, or be surpised if disease infect them. They are food for musketry, and possess the courage to fight, if they only knew how, or were blessed with the physical

powers to endure privation. Some of these raw young countrymen present a truly pitiable appearance when first forced to confront danger. Training for slaughter they possess our sympathies, for the fate which awaits them is deplorable in its awful certainty.

Cooling Drinks for the Wounded.

We understand there is a great lack in the French and Prussian hospitals of refreshing and nutritious beverages for the parched soldier, thirsty with the heat of fever from his wounds. We suggest to those ladies and philanthropic gentleman at home interested in sending out lint and chloroform, to forward a supply of barley and concentrated solution of milk; for we learn great numbers of the wounded soldiers have succumbed to diarrhœa, no doubt induced by the acid drinks which they consume, that may for a time appease their thirst, but never nourishes them, and terminates in a relaxation of the bowels, which is invariably fatal. We recommend this important subject to the consideration of those interested and acting at home through pure humanity. Barley for making drinks is much needed, and we know no better article than it, as the barley-water can be prepared according to taste with a little lemon-juice.

Nuisance Prevention in Ireland.

Bumbledom is as efficient in its guardianship of the public in Ireland as in England, and we are occasionally reminded rather more forcibly than agreeably of the executive qualities of Boards of Guardians and Town Councils in the removal of dangerous nuisances. A bad form of English cholera, with a widespread epidemic of diarrhœa, has broken out in Clonmel, and its spread is reported by Dr. Fitzgibbon to his Board of Guardians. The Mayor, as Chairman, thinks the occasion one for glorifying the Town Council as to its activity in carrying out disinfecting works, but the effect of his laudation is somewhat marred by the following statement from another guardian:

He was very sorry to be obliged to bring before the Board, *for the third time*, a terrible nuisance which existed on the Cahir road, and if some steps were not taken he would communicate with the Commissioners direct. There had been a habit of throwing dead horses into the quarry at Tubberaheena, but latterly they had left the carcases at the quarry at the top of the hill. *This morning two were there exposed, and the stench from them was fearful.* Characteristically, the Mayor and Chairman of the Guardians made answer to this statement. That "three or four magistrates passed that place every day. It was not his duty to look after the matter, and he would not do so. He considered the constabulary had power to prevent this nuisance." A guardian said he had brought the matter under the notice of the police, who certainly did what they could. The Mayor objected to the posting of warning notices or the appointment of a nuisance inspector. "If there was likely to be a continuance of the disease they might get assistance for Dr. Fitzgibbon, *but there was nothing to prevent them waiting for a week.*"

From proceedings like these, and from a long and dearly-bought experience of the maladministration and culpable laziness of Boards of Guardians, the Legislature ought long since have satisfied itself that, in entrusting even the smallest and simplest duty to such persons, they are effectually defeating their own object. It is astonishing and melancholy to see how completely in such matters the representative system breaks down, inasmuch as it places important responsibilities in the hands of men who know nothing, and care as little to release themselves of them.

The Economy of Hill Stations in Indian Military Sanitation.

The history of the 58th Regiment during its stay in India affords a very valuable and conclusive evidence of the faultiness and wastefulness of the existing regimental arrangements in that country; and, as an illustration to this effect, the *Pall Mall Gazette* has recently called attention to the health statistics of the regiment.

It so happened that for a long period half the regiment was camped in the plains and half in the hills, under conditions in which a comparison of the effects of climate in the two cases could be made with every chance of a sound conclusion being drawn. The 58th, composed of very young soldiers, was ordered to India in 1864, and while quartered at Benares in 1865 began to suffer much from sickness; so much so, that the ordinary hospital accommodation had to be supplemented by special means. At the end of the year the regiment, out of an average of 772 men, had lost 43 by death, and 41 by invaliding, or 108·8 per 1,000; further, "it would be difficult to exaggerate the enfeebled condition presented by the regiment on parade towards the end of the year," and the truth of this statement is attested by the fact that the admissions to hospital were 1,945 during the twelvemonth out of the 772 men. The right wing was now ordered to Senchal, a Himalayan station, 8,600 feet above sea level, with this result, that only two died and thirteen were invalidid during the first year of residence. In the following two years only three died, and the average daily sick did not exceed ten in a strength of over 400; in fact, the right wing exhibited a condition of health quite unsurpassed in any other station in the world. In the left wing there was quite another state of things. It remained at Benares, and during three years lost annually 27·2 by death and 44 by invaliding per 1,000; or, in other words, death took away seven times as many men in the left as the right wing, the invaliding being twice as great in the former as the latter, and the rate was rather increased in the right wing from the fact that a certain number of sick were sent to Senchal from time to time. Now came a change. The regiment in 1866 was ordered to reassemble at Allahabad in new cantonments. It did so, and lost during the next year 123 by death—53 being from cholera—and 81 by invaliding, or 279·8 per 1,000 from death and invaliding out of a force of 729 men, each of whom had been on an average in hospital three times during the twelve month. As the men of one wing suffered in about equal proportions with those of the other, Dr. Ambrose concludes that the assertion that troops which have resided a long time in the hills are more liable to be attacked by endemic disease in the malarial plains of India, when called upon to serve there, is not true. Dr. Ambrose forcibly reminds us of the costliness of the present system of keeping the great bulk of European troops in the pestiferous plains of India. Taking the cost of replacing each European soldier in India at £100, he remarks that in one year (1869) the loss to the State induced by disease in the 58th was 204 men out of 729, or £20,400 exclusive of minor expenses for hospital extras, moving from camp to camp, &c.

The Fever Epidemic in Liverpool.

At a special meeting of the workhouse committee, on Wednesday, the Chairman explained that the workhouse committee had thought it right to ask the district medical officers to meet with them so that they might consult with them and get their opinion as to the probable cause of the fever, and whether they would suggest that the patients should be treated at home, or ask the select vestry for more hospital accommodation.

Mr Hagger, vestry clerk, said they had altogether accommodation for 860 patients. They had now in hospital 731 patients, and last week they had resolved to set to work to make additional accommodation for 150 more, making a total accommodation for a number slightly over 1,000. The question came upon the committee whether they should content themselves with the present accommodation, and ask the medical officers to send in only such cases as absolutely required to be sent to the hospital, or whether the committee should provide still further accommodation.

In response to the wish of the committee, the medical gentlemen then each gave his individual experiences in the matter. With only one exception they were strongly in favour of the removal of the patients to the hospital, as they were there better treated, and their removal tended to prevent the spread of the infection. They were all as one as to its being highly infectious. Dr. De Zouche, in whose district it first broke out, said he could not say the fever was abating. If all the patients went into the hospital a great deal more accommodation would be required. A great many refused to go there, and he had treated as many at their own houses as he had sent to the hospital.

In reply to Mr. Hagger, Dr. Kirkpatrick said there had only been five or six deaths in the hospital from relapsing fever out of 300 or 400 patients.

Mr. Scott moved that a shed for the accommodation of sixty patients be at once erected at a cost of £360, which was seconded by Mr. Fowler.

The resolution was then put, and was carried by seven to three votes.

Cheap Physic.

The Metropolitan Mutual Medical Aid Society is not the only one—nor the worst of its kind. We have been favoured with a circular of one in Kent that in parsonic style "implores the working men *for their own good* to join the club that the clergy of the district support, and that offers them advice and medicine" at the munificent rate of one shilling and threepence a year. Cheap enough. Is it "cheap and nasty?" as the proverb goes.

Cholera.

A letter from Russia this week tells us of great fears about cholera, which, as we have already announced, has appeared at Odessa and other towns. Coupled with the rumours from the Seat of War, these indications are of great moment.

The Social Science Congress is to be held at Newcastle-on-Tyne, from the 21st to the 28th of September. R. Rawlinson, Esq., C.E., will preside over the Health Department.

Amendment of the Medical Act.

The following letter, which sufficiently explains itself, appeared in the *Times* of the 1st of September:—

Sir,—With reference to a recent report in your columns, we beg to state that at the late meeting of the British Medical Association, held at Newcastle-upon-Tyne, we found ourselves compelled to resign our seats on the council of that body.

As members of the General Council of Medical Education and Registration, we had advocated the main provisions of the Amended Medical Bill introduced into the House of Lords by the Lord President of the Privy Council—provisions which, in our judgment, were of the utmost importance to the public weal.

The Bill, it is believed, was withdrawn in the House of Commons by Mr. Forster, in consequence of the course pursued by the Direct Representation Committee of the Association. That course was subsequently approved by a vote of the Association at Newcastle.

We, therefore, could not, in justice to ourselves or to the members of the Association, continue any longer to belong to its executive.

The question of the permanent construction of a Medical Council of Education is one of grave importance. It is intimately connected with other questions and interests entirely extra-professional, and it cannot, therefore, be properly dealt with by any hasty or one-sided legislation.

We are, Sir, your obedient servants,

George Paget, Cambridge.
William Stokes, Dublin.
Henry W. Acland, Oxford.
H. Wildbore Rumsey, Cheltenham.
Dennis Embleton, Newcastle-on-Tyne.

The Result of the Newcastle Meeting.

The waning power of the British Medical Association is seen in the fact that the Newcastle Meeting has been followed by the resignation of Drs. Stokes, Acland, Paget, Rumsey, and Embleton—perhaps the five most influential and important names, all members of the Medical Council also. Who will now deny that the Association is ruled by a clique? We are glad that these upright men have withdrawn their countenance from such a body as that which sealed its own doom by its action at the Leeds meeting. Newcastle, we are told by those of our staff who were present, was more than discontented, not only about Medical Reform, but about the other conduct of the Council and its precious committee.

Cypress and Laurel.

Scarcely a week elapses that we have not the melancholy duty of recording the decease of some esteemed and gifted member of our Profession. Last week, we regret to learn, Dr. John Wilson, F.R.S., died. During the long period of an eventful life, this gentlemen did much valuable service in exalting his calling, and benefiting his fellow men. Being on the retired Naval list, his important services were forgotten, and, when in the decline of life, he was offered knighthood, he refused it. There is no profession, other than that of medicine, where the honours are offered too late; or what is worse, most frequently not at all. The odour of the fresh gathered laurel-wreath is not much

needed, when the cyprus tree beckons to rankly waving grass beneath. Surely, it is high time the State paid honour to our leading men in the three kingdoms. Members of what class, or profession, of living men have done more than these for suffering humanity? We pray the State not to tarry over this matter, but confer the honours whilst they will prove acceptable.

The Humanity of Guardians.

We have been favoured with the following, addressed to a correspondent of ours :—

[ORIGINAL.]

"Sir,—The following remark is entered in my application book by the Chairman of the Board yesterday, in reference to the case of J. M., wife of ——

"'The Board think it strange meat should be given to a dying person.'

"I am, yours, &c.,
"G. A., Relieving Officer.

"August 24th, 1870."

The inhumanity and ignorance of the Board from whom such a production emanated is scarcely worthy of alluding to, but the absurdity of the Chairman is only equal to the hard-heartedness and ignorance of men of his class, who occupy a position for which nature never intended them. Meat ordered for the purpose of preparing beef-tea, even for a dying person, ought not to be "strange." Perhaps the Chairman never heard of beef-tea, and labours under the delusion that the person for whom it was intended should eat it as *he* would. We suppose, "Where ignorance is bliss it is folly to be wise."

The Hunter's Rupture.

The season has again come round for recommencing the invigorating and exciting amusement of "riding across country" after the hounds or harriers. Hunting is one of the few pleasures which the country practitioner may claim his own, and of which he often takes advantage. It is no unusual thing to find the doctor after hurrying through his morning visits, in full chase in the hunting field. No one knows better than the doctor what risks corpulent men advancing in years, run in the excitement of fast riding over a rough country, taking fences as they come. Their own experience recals in the past frequent cases of rupture produced by hard riding, where the violent pressure from the diaphragm and abdominal muscles led to sudden protrusion of the bowels, where the parietes were weakest. Owing to the violent bodily exertion of leaping a high fence, where rising in the saddle was followed by falling heavily forwards, we have known the conjoined tendons yield, and *direct* hernia occur. Persons ruptured should never dare, unless they can thoroughly command themselves, to hunt, lest, carried away by a mad excitement, they convert an old, simple, reducible hernia, into an irreducible and strangulated one. For some seasons we have been in the habit of recommending patients of corpulent habit, who refused to deny themselves hunting, the wearing of closely-fitting abdominal supports, in the form of flannel belts. These should be made to fit accurately the person for whom they are intended, coming down to the pubes in front, and kept in position by a narrow perineal strap on either side fastened by buttons; any undue pressure upon any particular part will be thus overcome, whether produced by a concussion in the saddle, or violent pressure upon the abdomen by the diaphragm after fast riding.

Use of Anæsthetics in War Hospitals.

We learn with much dissatisfaction that the barbarity towards wounded soldiers involved in omitting the use of anæsthetics for operations on them is being practised at the Seat of the Prusso-French War, in a degree no less than that which it reached in the Crimea and in the inhuman American conflict.

To state that it is found impossible to make use of anæsthetics for capital operations in military hospitals is as much as to say that it is impossible to make medical war arrangements at all nearly perfect.

We imagine, however, that the disuse of anæsthetics is rather a matter of indifference than of inconvenience, and that surgeons are responsible in many cases for omitting to employ them when, though perhaps inconvenient, their use would be quite feasible. It may be that surgeons care less (under such circumstances than they might) for the infliction of pain, and we can easily understand that the desire to maintain a courageous bearing under all trials, would prevent the poor wounded soldier from asking to be saved the torture of an amputation, or extraction of a ball, performed on his quivering body. Every allowance should be made for the fact that surgeons in a war hospital are not to be placed in the same category as operators displaying their skill in an hospital theatre, yet we can conceive no insuperable difficulty in the administration of chloroform by an assistant while the case waits its turn for operation.

We confess we cannot regard as feasible the suggestion put forward by Dr. Thudichum in the *Times* that bottles of nitrous oxide should be supplied to the military hospitals. That agent has hardly established its superiority even in short operations in well-fitted laboratories; and for operations for gunshot wound, or for use by inexperienced hands, and in *impromptu* and unorganised hospitals, it appears to be the very worst anæsthetic which could be employed. If similar difficulties were involved in the use of all anæsthetics, it would be simply out of the question that they could be used at all.

The Working of Syphilis Prevention in India.

The Correspondent of the *Times*, writing from Calcutta, says :—

"I see that the opponents of the Contagious Diseases Acts in England appeal to India for facts to support their views. I express no opinion on either side, but it may interest you to know the latest facts on the subject in military cantonments and in the cities of Calcutta and Madras. In the former, an attempt has been made for years to secure freedom from enthetic disease by periodical inspection. Here and there a Lock hospital has been established. When the doctor and the commanding officer of a regiment worked well together, and the former was zealous in this special direction, all testimony goes to show that disease was kept under. Some years ago cantonment Acts were passed, under which inspection ought to have become systematic—I mean of the women. The cases seem to be rare in which the old parades of the men are kept up. This ought to have become systematic, but never has been so. I have carefully gone over the three latest sanitary reports for 1868 of the three Indian armies, British and Sepoy, and each is clear on this point, that the Lock hospital system had not been properly worked. On the whole, there has been a slight reduction of enthetic disease, but it would be too much to say that the diminution is due to preventive measures, just as it is to say

that preventive measures have been tried and have lamentably failed. The experiment has yet to be made on a proper scale, and to be continued with unflagging uniformity in every corps as well as every cantonment, and for a considerable radius round each cantonment. What are the facts? In all India, except Madras, Burmah, and Bombay, the number of British soldiers admitted to hospital with this class of diseases was in a mean strength of 33,452 so many as 217·7 per thousand in 1866, was 166·6 in 1869, and 199·2 in 1868. Half of all the admissions were due to fevers, but next to these come the enthetic diseases in each year. The reduction might seem in favour of the Contagious Diseases Acts, but Dr. Cunningham, the Sanitary Commissioner, writes of Lower Bengal that the fact that 663 soldiers out of only 2,059 were treated shows that the Lock hospitals had not produced the beneficial effect so much desired. He does not give the explanation, however, that with large cities like Calcutta, and civil stations close to cantonments, it was impossible to work these hospitals. If we look at daily sick alone, these diseases stand above fevers—365 British soldiers were on an average unfit for duty every day of the year from this cause, while only 311 were so unfit from fevers. We are soon told the cause. "In many stations the registration has been very incomplete. . . The women have frequently escaped surveillance." Again, "The irregularity in the attendance of the women . . . has been complained of . . . but the remedy which the rules provides for this had not been put in force as it ought to have been." It is a remarkable fact that the native army, though practically as many of them are unmarried or separated from their families as among the Europeans, suffer very little from these diseases in the very stations where there are most European victims. The proportion of admissions per thousands of Sepoys was 54 in 1866, 45 in 1867, and 43 in 1868. Caste, cleanliness, and other causes have much to do with this difference. In Madras the state of the case is much worse. The proportion of diseased British soldiers per thousand in a mean strength of 10,766 was 562·2 in 1866, was 412·7 in 1867, and 435·8 in 1868, or almost every second man. Again, we are told that many of the women escape registration, and there is much clandestine intercourse. In Bombay, in 1868, the admissions were 202 per thousand in a strength of 10,524 rank and file, or one fifth of the total sickness. Here also we are assured that 'a systematic and satisfactory supervision has not been attained in any of the large stations in the Presidency.'"

Worm Cakes.

We are led to understand the trade in worm-cakes is rapidly increasing, and that the quantities consumed in some districts is truly enormous. Correspondents, resident in manufacturing localities, tell us of the common and baneful practice which only too generally exists of parents indiscriminately administering to their children these cakes upon the first approach of indisposition, which is usually assigned, upon presumptive evidence, to the existence of worms in the intestinal tract. Some of these nostrums, we believe, contain scammony, baked with brown sugar and flour into an agreeable cake which children freely eat.

A correspondent narrates to us a series of cases wherein a most violent and serious, and, in three cases, fatal, form of diarrhœa was induced by the consumption of cakes manufactured by a certain maker, which he considers contain calomel. The process of baking in the oven is against this. One description of worm-nut, we are told, has santonine, and another simple jalap. Be the exact formula what it may, our duty owing to the pernicious, we may say dangerous, nature of an absurd practice of treating every child without discrimination for worms is to enter our protest against it, and to recommend when fatal cases of diarrhœa occur traceable to these cakes, for the medical gentleman in attendance to communicate with the Coroner.

We are pleased to hear that Dr. Andrew Wood has in the press a volume of translations from Horace.

The annual meeting of the British Archæological Association is now being held at Hereford.

Hampstead Heath seems again to be in danger. Since the law suit was held over, more land has been enclosed. This seems to be a want of good faith.

According to the *Eastern Post* the Prussian Government has ordered 200,000 wooden legs in this country. What a grim comment on glory!

The Government has expressed its willingness to appoint a gentleman who is opposed to the Contagious Diseases Acts as one of the commissioners for inquiring into the working of these Acts.

The late Sir F. Pollock was standing counsel to the Royal College of Surgeons of England, and otherwise intimately associated with the profession, in which he always evinced great interest.

The fracas between a surgeon and a solicitor, which has created a good deal of interest and gossip in and around Nottingham for the past few days, has been settled out of Court, by mutual arrangement, our confrère handing over to the fund for the sick and wounded a cheque for £5.

We regret to announce the death of Dr. Bolley, the celebrated Professor of Chemistry at Zurich. The deceased professor was but fifty-eight years of age. His famous work on *Technico-Chemical Research* may probably be known to many of our readers.

In our supplement last week we announced the decease of Mr. Clement, M.P. He practised many years in Shrewsbury, which was his native town. He was one of the very small band of actual practitioners who have obtained a seat in the House of Commons. He was a Fellow of the Royal College of Surgeons of England, author of an essay on "Urinary Diseases," and several contributions to the medical journals.

Apropos of the meeting of volunteer medical officers, our able contemporary, the *Globe*, inquires what they have hitherto been thinking about. Perhaps the inquiry may stimulate them to more than talk. At a time like this the volunteer-surgeon should be as effective in his department as the rifleman in his. We have already directed attention to methods of obtaining experience. Let us add that gentlemen should not enter this service who are too engrossed in practice to attend to it, nor with the idea that it is a merely ornamental one.

EDINBURGH.

The University.—Mr. Brodie has completed his busts of the late Professors Goodsir and Lee, which are shortly to be presented to the Senatus of the University.

Correspondence.

A VISIT TO PARIS IN WAR TIME.

[LETTER FROM DR. C. R. DRYSDALE.]

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Nothing can be more afflicting to those who, as all members of the Medical Profession do, take an interest in the physical welfare of their neighbours, than the position of this great and wealthy city at the present moment. Every question relating to the good of the sick and suffering is postponed to a more convenient season. No topic is of the slightest interest to anyone, medical or non-medical, at present but that of how to kill the Prussians. What a deplorable effect is produced by the ambition of the few, and the professional zeal of those officers and military grandees who alone, surely, can ever be gainers by such a terrible slaughter as is afflicting all our hearts at present. To think that the countrymen of La Place, Lænnec, and Voltaire are killing and being killed by the countrymen of Gœthe, Schiller, and Virchow is a bitter thought, and might make anyone less confident in the ultimate power of science in civilising mankind despair of the future of the race. Intellect, it must be confessed, is but a weak force in society as yet; but, as science, "the only regenerator of mankind," is daily being more widely worshipped by members of all civilized nations, we may, even in the din of battles, maintain a hope of lasting peace after this sanguinary conflict.

Thus, notwithstanding my intense sympathy with our charming French neighbours of Paris, and the almost futile task of attempting to obtain any information upon ordinary subjects this year, I have, nevertheless, been able to visit one or two gentlemen whose opinion I have long wished to hear upon certain questions of national importance, as the matter of public hygiene—*e.g.*, I have long taken a great interest in the question of whether the results of the French system of regulating and registrating prostitutes had really produced good results or not in France, even in the matter of the prevention of disease. Our most respected writer, Mr. Acton, seems quite convinced that the French system has made Parisian prostitution much less dangerous to the health of those who make use of it. And I think that Mr. Berkeley Hill is of the same opinion, although he has not *publicly* stated his conviction to this effect, as far as I know. To assist me in my researches in this matter, I first called the other day on M. Lefort, but found that he had gone off to the war as surgeon to the first ambulance. Check number one. I then went to the famous police office at the Rue de Jerusalem, so familiar to the readers of the works of Balzac, and asked for the head of the *Bureau des Mœurs*, M. Lecour, who has just written an admirable work on the subject of prostitution in Paris and London.

This gentleman, to whom I was not unknown, as he has mentioned my name as an authority on this subject in his recent work, received me with great kindness; but, after a very short conversation, informed me that his functions as Chief of the Bureau at the Préfecture of Police were quite at an end at present, and that he was constantly and absorbingly engaged with his duties as *Commissaire Interrogateur* "on account of the war." He referred me, therefore, for this year to his work for all his opinions, merely adding that he had received from Mrs. Josephine Butler pamphlets on the side of abolition of the system for which he is so staunch an advocate. We separated, in hopes of better times, when murder and rapine may again give away to peace; and schemes for the amelioration of unfortunate women, and the diminution of indigence may again be considered as the grand aims of all truly-civilised and intelligent citizens.

In his work on "La Prostitution à Paris et à London, 1789-1870," M. Lecour asks the question—"How many venereal patients are there in Paris?" and attempts to answer it by saying that in 1868 the Midi Hospital received 3,185 cases; the Lourcine 1,024; and that the general hospitals, in the same year, 1,551 cases; whilst Saint Lazare had 1,694 venereal cases in that year, and the Military Hospitals 1,907 cases. He adds to these 435 cases among the military of the department, and makes a sum total of the number of cases of venereal disease of about 9,500 among hospital patients. This cypher is not sufficiently accurate for my taste. For instance, I asked at the Hôpital du Midi whether there were not many cases of syphilitic and venereal disease treated in the out-patient departments of the larger hospitals. M. C. Mauriac replied that it depended on the surgeon who gave consultations at the large hospitals how many were seen there. I do not think, then, that M. Lecour, who, I believe, is *not* a medical man, is sufficiently aware of these facts; and I therefore believe that his hospital statistics are almost worthless, except in so far as the Midi, Lourcine, and Saint Lazare Hospitals are concerned. In addition to this, there are large dispensaries, or *consultations*, held by Dr. Langlebert and other doctors of the "Ecole Medicale Libre," where only venereal cases are seen, and these are not spoken of by the able author, Lecour, in his statistics.

He says, indeed, that without fear of being taxed with exaggeration, we may consider the cypher (9,500) as representing the fifth part of the number of venereal patients at Paris, who are treated at home by doctors, or who go for prescriptions to chemists' shops; and proposes the figure 47,500 as the number of cases of venereal disease in Paris annually. I believe that he has been greatly deceived in giving such a low figure, although it certainly shows that all the *reglementation* in the world has anything but got rid of the contagion it has been framed to prevent.

Had M. Lecour done as we did in the Harveian Society's Committee in 1867—*i.e.*, written notes to each hospital to ask what was the average number of venereal patients, in and out patients, of each hospital, and the proportion borne by these to the total number of cases seen, both in Paris and in the larger towns in France, he would, in my opinion, have found that the returns would have shown a much larger cypher than that of 9,500 for the hospitals of Paris. I say this the more frankly because I see that M. Lecour has quoted largely from the report on the quantity of venereal diseases, draw up chiefly by myself in 1867 from replies sent to our Harveian Committee by a large number of hospital surgeons or house-surgeons in England, Scotland, and Ireland.

A notable fact must be kept in mind, *i.e.*, that the size of the two cities, London and Paris, seems not to be so very different as it was. Thus, according to Lecour, the census of 1865 showed that Paris contained 2,150,916 inhabitants, and London had by that year's estimate 2,803,989.

The work of M. Lecour is a curious proof how persons may demonstrate a proposition to others, and yet think that they have clearly shown the very contradictory fact to be true. He shows that for the last twenty years there has been going on in France a work of social transformation. "The religious sentiment is weakened; toleration for venal and scandalous gallantry has become a part of our manners, whilst prostitutes have invoked, or rather other folks have invoked for them, immunity as citizens . . . . so that, whatever the police does to repress and watch over these women (and the duty of the police is a more complex one than most persons dream of), it does not satisfy the exclusive exigences of medical science, whose thoughts are solely occupied with the peril arising from syphilitic contagion."

In another part of his work (chap. xvi.) he shows that the control of prostitution is slipping out of the hands of the police, as follows:—In 1855 there were 611 girls inscribed on the police rolls; in 1869 only 370 In 1855 there were 204 tolerated houses; in 1869 only 152. In 1855 there were 1,860 women in these same houses; in 1869 only 1,206. In 1855 there were 2,429 isolated prostitutes; in 1869, 2,525. And, lastly, a state of things affecting to the mind of any true French policeman, or English imitator of that type, there is a considerable increase every year of the number of women styled *insoumises*, or unsubjected. This is, you know, Mr. Editor, the most thorough "subjection of women" known either among white or black nations. These women scarcely ever marry, or get out of the *souricière* or trap laid for them by the Bureau des Mœurs; but continue at their miserable trade till death releases them, whilst in our benighted London, where there are no *sousmises, as yet*, the girl of the town gets married, perhaps as easily as her sister, and leaves this business in a short time for ever.

There are, you know, in London and many of our provincial towns, societies called Refuge Societies, where some benevolent persons strive to recall some of their unfortunate fellow countrywomen to the paths of industry, frugality, and temperance by addressing them in the words of the great founder of Christianity, "Neither do I condemn thee." I have myself seen my friends Mr. Wilson and Mr. D. Cooper handing cards to the poor young things, whom poverty and accursed circumstances, for the most part, have driven upon the streets,

inviting them to come, when tired of this life, to one of the offices in London, when they will be taken into a home, and assisted in every way to re-enter industrial life, and become again honest and useful members of society. I have seen this with great pleasure—and the only oasis, in my mind, in the Parisian system of total subjection and slavery of prostitutes is the fact that there is some slight, but most inadequate attempt made to get a few of these poor "white slaves" to quit their business.

As far back as the year 1198, a hospital, which has now been made into the General Hospital of Saint Antoine, received converted public girls. At present, the only benevolent institutions at Paris, which are in relation with the police office are, for Catholics, L'Œuvre du Bon-Pasteur, and L'Ouvroir de Notre-Dame de la Miséricorde; for Protestants, L'Œuvre des Dames des Prisons; for Jews, la Maison de Refuge. The Œuvre du Bon-Pasteur was founded in 1819 by Abbé Legris-Duval, with the aid of two ladies, de Croisy and de Vignolles. It receives, in an Asylum placed under the direction of the nuns of Saint Thomas de Villeneuve, young girls from sixteen to twenty-three, who have been drawn into vice by abandonment, solitude, or bad example. The ladies of this Asylum go to seek the girls, either in the Lourcine Hospital, or even in the Saint Lazare Prison. They instruct them and exhort them with a view of making them virtuous; occupy themselves individually with each; take all kinds of pains to render their return to virtue easy; and, without preventing aid to them by other methods, as, for example, their being taken by provincial families as domestics, they open the doors of their convent to them. Those whose condition of absolute loneliness, or the unworthiness of whose parents seems peculiarly to condemn them to a life of misery, are preferred for admission into the Bon-Pasteur, where their time is divided between religious exercise and sewing. I wonder, Mr. Editor, how many men would become chaste if this were the reward of their chastity? Women, however, are easily contented. These girls, whose admission into the convent is gratuitous and voluntary, are always left free to quit it when they please.

This Convent of the Bon-Pasteur, as it covers, in some measure, with its protection orphans and abandoned and suffering girls, who are the least fitted to confront the difficulties of life, has but little renewal of its protegées. It contains about 135 young girls. The annual number of admissions is only about 25; and most generally the vacancies are caused by the death of one of the young women from consumption, or "some disease contracted during their time of debauch. Many of these unfortunates, whose health has been ruined, become infirm, and a prey to sufferings which medical science cannot cure." The Convent of the Bon-Pasteur is insufficient as a building and resource for all the unfortunate girls who ask for its aid; and thus the ladies of this charity seem to occupy themselves almost entirely with the unsubjected girls at Saint Lazare.

The introduction into the service of the Saint Lazare Hospital Prison of the Nuns of the order of Marie-Joseph had, as a consequence, the creation by these nuns of a "work" called the "Ouvroir bleu," a name derived from the colour of a ribbon which distinguishes the young girls received into it. The nuns, who are daily called upon by their mission at Saint Lazare to endeavour to raise the character of the girls confided to their care, could not long remain indifferent to the masks of repentance exhibited by some of these girls. They were terrified at the ideas of such re-entering debauchery again as inscribed prostitutes, or at such girls in whom they had developed good feelings, being jostled upon the streets; and, to secure the means of continuing out-of-doors their work of charity towards these latter, they founded, provisionally, in the prison of Saint Lazare itself, with the assent of the police, the work just spoken of, and in which they retained, in the name of hospitality, and until they could get a place for them, the girls who asked them to do so, and who, if they went out, would be likely to find themselves exposed without any asylum. This society ceased to exist after having attained admission for its protegées into the Ouvroir de Notre-Dame de la Miséricorde, in the Rue Paris-Vangirard, No. 440. This "home" is placed under the direction of the nuns of the order Marie-Joseph, and was founded in 1843. It receives not only the class of girls taken in by the Bon-Pasteur, but also all girls who are commencing to be prostitutes, and who would inevitably fall back into it were they to quit the Prison Saint Lazare without aid and guidance. The girls who enter are employed in sewing; and, at present, there are about 90 of them, consisting of 86 young girls, aged from eighteen to twenty years, and 4 married women. After a certain sojourn in this establishment, and when they appear to be likely to conduct themselves well out of doors, they are placed by the nuns as domestic servants, or work-girls, or reconciled with their parents. Since 1862, 57 have returned to their parents; 62 have become servants; 25 have become work-girls; 19 have got married; and 7 died. I need not say how miserable the result seems in comparison to the thousands who are rescued from prostitution by the London Societies. A certain part of their wages is set apart for them to buy clothes with when they leave this "home." It would be well if public charity would help on so good a work as this.

The special *work* for the protestants, called "Œuvre Protestante des Prisons de Femmes de Paris," was founded in 1839, and is now attached to the institution of the *Diaconesses*, founded in Paris in 1841 by a protestant pastor named Vermiel. This contains, independently of a reformatory, where are imprisoned some vicious children at the desire of the parents, the quarter called the "Refuge et la Retenue," where young girls who repent, and women, are received. In the twenty years ending 1861, the work of the Diaconesses has received more than 4,000 persons (sick persons, children, and repentant women). Besides the girls received into the Refuge, the Association assists women when liberated from prison, and whom, in the visits paid to Saint Lazare, its members think to be most worthy of being assisted. It sends some of them home to their families or native provinces, and for those who cannot quit Paris it tries to take them into the Refuge, or get them into service. About 100 women prisoners, half of them French, are annually assisted.

The *work* of the Refuge for young Jewish girls is of quite recent creation—it dates from 1866, and has for its principal object those young women of the prisons judged by the application of the Articles 66 and 67 of the penal code—that is, who must remain in the house of correction until a fixed age. This Society also receives besides some young girls, for the most part orphans, who cannot remain left to themselves, or whose conduct is not free from reproach, There is also the Société of Patronage for the sending home of the young girls who have no place, and of women abandoned by their friends. Since the year 1844 this Society has paid the fare of more than 9,835 women to their native country.

M. Lecour makes a remark, which will be felt to be most true by all persons who have occupied themselves with such subjects in London and Paris—"Out of the circle of their assistance, and of the pious persons who devote themselves to this service, and who thus fulfil a true priesthood, these different societies, so beneficent and of such lofty aims, are, with us (in Paris), almost unknown by the public and the poor. In England, where individual action and private imitation play an important part, such like institutions would call down the attention of all upon them, and would soon see flow towards them many charitable gifts, which could not choose a better employment." With this sentiment of M. Lecour's I heartily sympathise; but I wonder that he does not see in it the explanation of the failure of the French system, which he has so well exhibited in his work, to *moralise* the French prostitute, or prevent the utter degradation of so many unfortunate French women. Many of his compatriots understand this far better than M. Lecour.

For instance, I found, in a conversation which I had the day following with Dr. Pascal, the eminent editor of the medical journal, entitled the *Mouvement Médical*, that he quite took my view of the system, remarking that as a means of public hygiene, it was most dangerous to take the matter of protection from venereal disease under the command of any police. In this, as in many other questions of hygiene, the only way to get rid effectually of such contagions is to instruct the citizens of the dangers he or she incurs by prostitution, and to provide, said Dr. Pascal, sufficient occupation for the female sex. All other measures are dangerous to liberty, and to public health itself, as they give a fallacious sense of security, and thus tempt persons into dangerous *liasons*. As to the proposal of M. Lefort to include some 30,000 women in Paris in the ranks of the subjected, we both agreed that it was a *reductio ad absurdum* of a system, which has *had its time*; but now requires to be swept away before better systems can be applied. There are some other remarks on the causes of prostitution contained in the works of M. Lecour which, if you will grant me space in your most catholic journal, I should like to criticise in a short time. This epistle is already too long.

I have seen very few of the wounded soldiers from the wars. Presumably, they will soon be sent into Paris, as beds are being kept for them at the Midi and Saint Louis, and other hospitals. Still, I do hope that very few of them will be put in the really very unhygienic Parisian Hospitals, or we shall hear of a terrible mortality among these poor sufferers from the madness of a few. So great is the patriotism of all with whom I come in contact here, that I think it probable that all, save the smallest minority, could easily find place in private houses, or small suburban or provincial hospitals. I am glad to hear that subscriptions for these brave men are pouring in both in England, and in Ireland and Scotland. It is not the poor soldiers who are in fault, but the thinkers and writers of Germany and France, and the accursed love of power and military glory which still exists in both Prussia and France.

I remain, Sir, yours obediently,

CHARLES R. DRYSDALE, M.D.,
M.R.C.P.L., F.R.C.S.E.

Paris, August 21, 1870.

THE TRAVELLING OF NEEDLES UNDER THE SKIN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—After reading the interesting case narrated in your independent journal of the 17th inst., from the pen of your clever contributor Dr. Z. L. Johnston, of London, and the *apropos* communication of your much respected correspondent Dr. Sharkey, of Ballinasloe, Ireland, respecting the meanderings of needles under skin, and their removal, I feel tempted to lay before your numerous readers the following history of a regular *human pincushion*, which I find recorded in Wylie's "Old and New Nottingham" :—

"Kitty Hudson, who at one period was known as the 'Arnold Post,' was born at that village in 1765, and when six years of age was left with her grandfather, Mr. White, the sexton of St. Mary's, Nottingham. Here a young woman resided in the capacity of a servant, who used to reward Kitty with a stick of toffy for every 'mouthful' of pins she procured in sweeping the pews and aisles of the church. The poor child followed this practice till she could neither eat, drink, nor sleep without pins or needles in her mouth. Often she got out of bed to supply herself with them that she might induce sleep. To such an extent did she carry this strange practice that, ere it was discovered by her friends, her double teeth had almost disappeared. At length she began to perceive a constant numbness in her limbs, and a great inability to sleep. After various medical applications, she was removed to the general hospital. Between the time of her admission and June 12th, 1785, when she was finally 'dismissed cured,' she underwent a most astonishing series of operations. Quantities of pins and needles, and pieces of bone were extracted from her feet, legs, arms, and other parts of her body, while portions of her breasts were cut off with the knife. While in the infirmary, a young man named Goddard, who 'had sweethearted her from a child,' happened to be an out-patient for a complaint in the head, through which he lost an eye. He used to cheer her by saying he would marry her if she lost all her limbs, provided her life was spared; and she afterwards said it was the kindness of this young man, and her attachment to him, which enabled her to bear up under her protracted sufferings. Six months after her discharge from the infirmary, she was married to the faithful Goddard, to whom she bore nineteen children. It is supposed she died in Derbyshire, whither she went on her husband's death."

Dr. Sharkey will allow in Ballinasloe *parlance* that the above "bangs Banagher;" and I think Dr. Johnston will admit, however ready and clear his plan of curing a patient who baffled so many, that Kitty Hudson takes the sunshine out of "Windfull's" husband.

Your obedient servant,

Aug. 25th, 1870. CANTHARIDES.

LIQ. PEPSINÆ AND "LIQ. ERGOT (LONGS)."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the very favourable mention, made in your last number of the preparations of "Liq. Pepsinæ" and "Liq. Ergotæ" introduced by me some time since, and described in former numbers of your valuable paper, the writer through some misunderstanding, says, "it was to be regretted that the manufacturers, Hamilton, Long, and Co., had patented the preparations, thereby adding to the cost."

As this would lead many to suppose that the price was so high, as to limit their being generally used, I wish to say, that these preparations have not been patented, but on the contrary, the formulæ freely published in former numbers of your paper, with the feeling, that medical men have a right to know what they order in every instance, as the use of secret nostrums is mere quackery.

The Government stamp, which was affixed to the bottles, is necessary in compliance with the law in England, with regard to all preparations of medicine made up for sale; no such import is levied in Ireland.

I may add that "Liq. Ergotæ" to which these remarks more particularly apply, is vended at about the price of powdered Ergot, some mere trifle being added to cover cost of bottles, &c.

Your obedient servant,

EDWARD LONG.

Dublin, September 2nd, 1870.

PRIVATE LUNATIC ASYLUMS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Permit me briefly to thank you for your favourable article in your last issue on the subject of "Private Asylums for the Insane," especially as such are so seldom noticed, except unfavourably in the public newspapers and journals, and as their alleged abuses so frequently form subjects for sensation chapters in novels and paragraphs in newspapers.

But would it not now be but just to us in Ireland to favour our establishments with visits similar to that paid by you to our brothers in Wales, and if we shall be found to deserve the same favourable publicity of names, arrangements, &c., as he has been so fortunate as to secure, that such shall be allowed us.

I do not hesitate to say that, notwithstanding considerable difficulties, existing in Ireland, not in England, my establishment can favourably compare with that of our Welsh friend. I also can introduce you amongst the voluntary inmates—insane and sane.

I do not doubt that my brother proprietors of "Private Lunatic Asylums," in Ireland, feel as I do in this matter, and can equally with me fearlessly invite your inspection.

You will, I doubt not, see the justice of publishing this letter, especially as, unfortunately, without sufficient reason, their exists in Ireland a tendency Englandward, in more matters than the treatment of the Insane, without much probability of a return flow of patronage.

Very faithfully yours,

DAVID JACOB, M.D.,
Proprietor, Midland Retreat.

Maryboro, September, 1870.

[Our Correspondent only anticipates our intention to give the fullest credit to the excellent arrangements of Private Asylums in Ireland. We had intended noticing the subject in connection with the "Report of the Inspection of Lunatic Asylums," which has just issued from the press, and would have done so in our present publication, but that we cannot, in view of the issue of the "Student's Number," next week take up new work. The matter shall have the earliest attention.—ED. M. P. AND C.]

Medical News.

Ipecacuhana.—It is satisfactory the *Asiatic* remarks that, amidst all the turmoil and excitement of financial perplexities, the authorities are not neglecting the material interests of India, by directing their attention to the introduction of one of the most useful plants of the world, ipecacuhana. The efficacy of ipecacuhana in the case of dysentery is said to have been satisfactorily established. The plant thrives both on the plains and the hills, the gardens at the Neilgherries and Calcutta being equally favourable to its growth. Dr. John Murray has the credit of directing the attention of Government to the subject, and as a nursery is to be established in England, from which strong and healthy plants will be sent to India, we may fairly calculate on complete success, and the steady extension of this valuable remedy.

University of London.—The following gentlemen have passed the First M.B. Examination for Honours:—

Anatomy.—*First class.*—Henry James Benham, Exhibition and Gold Medal, University College; Ebenezer Geer Russell, Gold Medal, Guy's Hospital.

Second class.—William Smith Greenfield, University College; George Birt, Sydenham College, Birmingham.

Physiology, Histology, and Comparative Anatomy.—*First class.*—Henry James Benham, Gold Medal, University College; Sidney Coupland, University College—Ebenezer Geer Russell, Guy's Hospital, equal.

Second class.—William Smith Greenfield, University College.

Organic Chemistry, and Materia Medica and Pharmaceutical Chemistry.—*First class.*—Charles Atkinson Nankivell, Exhibition and Gold Medal, University College; William Smith Greenfield, University College; Ebenezer Geer Russell, Guy's Hospital; George Birt, Sydenham College, Birmingham.

Second class.—Sidney Coupland, University College; Henry James Benham, University College.

Sewage.—Mr. Henry Bird, of Christow, writes to the *Field*:—Having some years ago recommended the use of aluminous compounds, sulphate of zinc, middle current tanks, and acre filter beds, to unload sewage waters of the sewage they have conveyed from towns, I trust you will do me the favour to insert in your paper the following remarks:—1. That the use of sulphated clay in large middle current tanks will so unload the sewage water, that it will flow into large streams and the sea without causing any nuisance. 2. That acre filter beds, one-sixth part being used at a time, the other five parts being cultivated, will secure the filter beds from the growth of the sewage plant, and render the waters fit to flow into any streams and for any purposes. One acre filter bed is sufficient for a population of 1,000 persons. 3. Burned bones greatly assist in purifying sewage, and increase the value of the dried sewage. 4. Sewage dried with diluted sulphuric acid contains most ammonia, and is worth £1 1s. per ton, and equal in value to 100 tons of liquid sewage. 4. Sewage irrigation and all sewage works should be made at a distance from any residence, for all plans give off unpleasant smells in certain states of the atmosphere. In drying sewage (with ordinary care) there is no smell occasioned; the burned bones and other deodorants prevent it. 5. For small towns and villages iron charcoal commodes are the best for collecting sewage. 6. A pair of large tanks or ponds with a vertical and horizontal culvert, and the use of 2lb. of sulphate of iron twice a day, would render waters inert, from mines containing lead, arsenic, and copper.

Unfounded Charge against a Surgeon.—On Thursday last, the jury without hesitation, returned a verdict of "Death from Exhaustion," in the case of Mrs. Walker, who died from flooding after delivery. The husband however, refused to believe this, and actually charged Mr. Simpson of Clerkenwell, with causing her death by the use of instruments. At the trial it was proved that no instruments whatever were used in the accouchment, and that he had no reason whatever for such a complaint. Such conduct deserves severe punishment.

American Statue to Harvey.—*Nature* announces that it is proposed to erect a statue of Harvey, the discoverer of the circulation of the blood, in the Central Park, New York, and large subscriptions have been received for that purpose. It is to be of bronze, of colossal proportions, representing "Harvey at the moment he felt convinced he had made the great discovery that has immortalised his name." Verily the American sculptors have a pleasant task before them. How does a philosopher usually look under such circumstances.

Luxuries without Licence.—Mr. Oakman, a surgeon of Battersea, was last week fined £60 for keeping a horse, carriage, and servant, without the licence required by the new Act. We commend this to the attention of any of our readers who may have overlooked the requirements of this Act.

The Siamese Twins.—We hear that Chang and Eng, arrived in Jersey City on the 13th of August from Europe. Our readers will remember that some time since they came to this country to take medical advice as to whether they could safely be severed from each other. About two days out from Liverpool Chang was stricken by a paralytic shock, depriving him of the use of his left side, and is now far from being well, while Eng continues in perfect health.

NOTICES TO CORRESPONDENTS.

*** Correspondents not answered in the current number should look at the notices in the following week.

Notice to Subscribers.—*The Publishers beg respectfully to remind those Gentlemen who have not paid their Annual Subscription, now overdue, that the most convenient mode of remittance is by Post-office Order, or cheque, which should be made payable, in England, to Albert Alfred Tindall; Ireland, Moffatt and Co.; Scotland, Maclachlan and Stewart.*

A Constant Reader.—The Conference in Geneva, in October, 1863.—Captain Brackenbury thus sums up the work it accomplished:—"The Conference was attended by thirty-six delegates, fourteen governments—including those of Great Britain, France, Spain, Austria, Prussia, Italy, Russia, and Sweden—being officially represented. A proposed code of international enactments was discussed during four days; and the main recommendations agreed to were the formation in each country of a committee, to co-operate with the army sanitary service, in communication with the Government; that such committee should occupy itself in peace with preparing supplies of hospital stores, training volunteer nurses, &c.; that during war national committees should furnish supplies and nurses in aid of their respective armies, neutral nations being invited to aid—and that, if permitted by the military authorities, volunteer relief agents should be sent to the battle-fields, wearing a badge of a red cross on a white ground. The Conference urged Governments to aid such national committees, and to declare the neutrality of hospitals, of the official *personnel* of the sanitary service, the unpaid nurses, the inhabitants of the country who might aid the wounded, and even the wounded themselves: and suggested the adoption of a distinctive and uniform badge for all hospitals and sanitary officials. Within a few months fifteen States expressed their willingness to accept these propositions as part of an international code, and the Swiss Federal Council summoned a Congress to complete an international convention. The representatives of sixteen States assembled in Geneva on the 8th of August, 1865, and accepted, with small modifications, a treaty embodying the proposals of the Conference held in the preceding year. Twelve of the sixteen representatives signed the treaty at once. It has since received the accession of all the civilized powers of the world, with the exception of Austria, Turkey, and the United States."

To the Editor of "The Medical Press and Circular."

Dear Sir,—How will the "Poisons' Bill" for Ireland, as published in last Press and Circular, affect physicians and surgeons not acting as apothecaries, but supplying medicines to their own patients, &c., and in very many cases not *using labels*! Will they be obliged to comply with the provisions of the "Bill," and be eternally scribbling in a book when they give any preparation of opium, ergot of rye, &c., &c.? 2. Does the well established etiquette in our Profession of attending, gratis, on its members, extend to the widows of same?

L.K.Q.C.P.I.

*** The Bill will affect all who supply medicines for gain, and they will be obliged to keep the necessary record of poisonous prescriptions. It is not usual to refuse gratuitous attendance upon the widow of a professional brother, so long as she remains a widow, and desires to claim the privilege.

Dr. Martin.—You will receive proof of your communication in due course.

Dr. Moore is thanked for his translation, of which proof shall be sent him.

M.R.C.S.—You will find the paper you refer to in the number of this journal for March 2nd.

VACANCIES.

Kent County Ophthalmic Hospital—House-Surgeon. Salary £100, with residence.

Surrey Dispensary—House-Surgeon. Election, September 26th.

Sussex County Hospital—Assistant-Physician. Election, 14th inst.

Newport Union—Resident Medical Officer for the Marshfield District. Salary, £40, exclusive of fees.

Billericay Union—Medical Officer. Salary, £72, with extra fees.

Shrewsbury Infirmary—A Dispenser. Salary, £70.

North Shields Dispensary—House-Surgeon. Salary, £100, with residence.

Castlebar Union—Medical Officer. Salary, £90, exclusive of fees (see advt).

APPOINTMENTS.

Greenhow, E. H., M.D., a Physician to the Middlesex Hospital.

Istance, R., M.R.C.S., Medical Officer for the Risca District of the Newport Union, Monmouthshire.

James, J., M.R.C.S., Assistant Medical Officer to the North Wales Counties Lunatic Asylum, Denbigh.

Rugg, B.A., Resident-Surgeon at the Bournemouth Dispensary.

Woodman, J., F.R.C.S., Surgeon to the London and South-Western Railway Company for Exeter, and Surgeon to the London and South-Western Railway Friendly Society for the Exeter District.

Wyllie, R., Medical Officer for the Scalby District, Scarborough Union.

Marriage.

WHISHAW—OSBORNE.—On the 1st inst., at St. James's Church, Piccadilly, Dr. Wishaw, of the Indian Service, to Miss Willoughby, daughter of General Osborne.

Deaths.

BRETT.—On the 19th ult., E. S. Brett, M.R.C.S., of Bridlington, aged 66.
CLEMENT.—On the 29th ult., at Shrewsbury, W. J. Clement, M.P., F.R.C.S., aged 65.
GORMAN.—On the 30th ult., Dr. John Gorman, of Jeffrey road, Clapham road, formerly of Cadiz, aged 79.
JOHNSON.—On the 24th ult., at Birmingham, David Johnson, Esq., Surgeon, late of Newhall street, aged 41.
SNITCH.—On the 31st ult., in London, Charles J. Snitch, M.D., aged 74.

LIGHT WINES.—Although the consumption of Light Wines has trebled in England since the reduction of the rate of duty, they have not at present taken the position as beverages of daily and general consumption that we may confidently anticipate for them in the course of the next few years. That there has not been a more rapid increase is due in some measure to the high prices of that particular description of Light Wines, viz., those from the district of the Medoc, which more than any other is suited to the taste and requirements of this country. Looking at the many millions of Claret produced annually in the districts around Bordeaux, it must be admitted that past prices have been somewhat fictitious. Thus, although the vintage of 1868 was as abundant and similar in quality to those of 1864 and 1865, the prices of that year were higher than were ever before known in Medoc. Fortunately, however, the year 1869 has also produced an abundant and equally fine vintage, and this has caused a great change; the prices for most growths having been less than half that of 1868, and the remaining wines of the 1868 vintage in Bordeaux have been sold at prices little in excess of 1869. Thus, while the ordinary growths of the Medoc have been secured at prices admitting of their being sold as cheaply as the ordinary wines of less favoured districts, the choicest growths of the various châteaux need no longer be regarded as luxuries beyond our reach. The reports from Bordeaux mention considerable purchases having been made by the firms of Gilbey, Cruse, Clossman, Schröder, Southard, Wustemburg, &c., and we may presume that a large portion of these are intended for the English market. The fact that good wholesome Claret, which when diluted with water forms a beverage equally as cheap as beer, and far more refreshing, can be obtained through the medium of such agencies as Gilbey's and other houses, of the grocers in almost every town and village, is a great boon, and will no doubt bring about what medical men and other authorities so much desire, viz., a large consumption in this country of Light or Natural Wines. As far as price is concerned, there is no reason why Claret should not be consumed as freely as in Paris, the charges for duty and conveyance being about the same to London as to the French capital.—MORNING POST.

NATIONAL SOCIETY FOR AID TO THE SICK AND WOUNDED IN WAR.

President—H.R.H. the Prince of Wales, K.G.

Chairman of Central Committee—Lieutenant-Colonel Loyd-Lindsay, V.C., M.P.

A Donation of £5 (payable to Messrs. Coutts and Co., Strand), or an Annual Subscription of 5s. (payable to the Secretary), constitutes Membership.

The Central Committee request that each Local Committee will remit every Wednesday, to Messrs. Coutts and Co., the amount collected, advertising details in local papers, and forwarding a list of Subscribers to the Secretary.

They also request each Local Committee to establish its own Store, and send each Saturday to the Secretary a statement of Stores in hand, so that he may draw upon them as necessity requires.

C. J. BURGESS, Secretary.

2 St. Martin's place, Trafalgar square, London.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

Founded 1788. Incorporated by Royal Charter, 1864. The Members are reminded that a QUARTERLY COURT OF DIRECTORS will be held on the 12th OCTOBER next, at which Candidates for admission into the Society can be proposed. It is desirable that the Forms of Proposal be filled up and forwarded to the Secretary at least a week before the meeting. The Forms of Proposal may be obtained of the Secretary. The benefits of the Society are restricted to the Families of Deceased Members of not less than Two years' standing. The Secretary attends at the office every WEDNESDAY and FRIDAY, from 4 to 5 o'clock.

J. B. BLACKETT, Secretary.

53 Berners Street, W., September, 1st, 1870.

APOTHECARIES' HALL, BLACKFRIARS.—

The next EXAMINATION in ARTS will be held at the HALL on FRIDAY and SATURDAY, SEPT. 23rd and 24th, 1870. A Syllabus of the Subjects for Examination may be had on application.

An Examination in ARTS will again be held in the month of JANUARY, 1871. R. H. ROBERTSON, Secretary to the Board.

PRIZES IN MATERIA MEDICA AND PHARMACEUTICAL CHEMISTRY.

THE NEXT EXAMINATION for the SOCIETY of APOTHECARIES' ANNUAL DISTRIBUTION of PRIZES in MATERIA MEDICA and PHARMACEUTICAL CHEMISTRY will be held at the HALL of the SOCIETY on WEDNESDAY, the 19th, and FRIDAY, the 21st of OCTOBER, at TEN a.m. The Prizes consist of a Gold Medal and a Silver Medal and a Book.

Gentlemen intending to compete for these Prizes must send a written notice of their intention to the Beadle, on or before the Seventh Day of October, which notice must be accompanied by evidence of their being in attendance on the THIRD WINTER SESSION of their Medical Studies.—By order of the Court of Assistants,

R. B. UPTON, Clerk to the Society.

Apothecaries' Hall, London, August, 1870.

UNIVERSITY OF DURHAM.—COLLEGE OF MEDICINE, NEWCASTLE-UPON-TYNE.

The WINTER SESSION will commence on MONDAY, OCTOBER 3RD, at 2 p.m., when the President, the Rev. Canon WHITLEY, M.A., F.R.A.S., will present the Medals and Certificates of Honour to the successful Candidates.

The Annual Report of the Council will be read by the Registrar, LUKE ARMSTRONG, L.R.C.P.Ed.

The Inaugural Address will be delivered by T. C. NESHAM, M.D.

WINTER SESSION, commencing October 3rd, 1870.

Physiology—William Murray, M.D.
Anatomy—T. C Nesham, M.D.; Luke Armstrong, M.R.C.S., and J. Russell, M.R.C.S.
Dissections—T. C. Nesham, M.D., and Luke Armstrong, M.R.C.S.
Medicine—E. Charlton, M.D., and D. Embleton, M.D.
Surgery—G. Y. Heath, M.D.
Principles of Chemistry—A. F. Marreco, M.A.
Practical Pharmacy—Barnard S. Proctor.

SUMMER SESSION, commencing May 1st, 1871.

Midwifery—C. Gibson, M.D.
Botany—J. Thornhill and W. C. Arnison, M.D.
Medical Jurisprudence—A. S. Doukin, M.D.
Materia Medica and Therapeutics—Thomas Humble, M.D.
Practical Chemistry—A. F. Marreco, M.A.
Operative Surgery—G. Y. Heath, M.D.
Pathological Anatomy—C. J. Gibb, M.D., and G. H. Philipson, M.D.
Medical Tutor, Supervisor of Dissections, and Curator of the Museums—W. H. Spencer, M.A., F.L.S.

Hospital Practice at the Newcastle Infirmary, which contains 230 beds, and in which the required Clinical Lectures are delivered. Number of Patients last year, 21,479.

Perpetual Fee, 17 guineas.

Two Resident Clinical Clerkships, four Resident Dresserships, and four Non-resident Dresserships, are gratuitous, at the disposal of the Physicians and Surgeons.

Midwifery, Diseases of the Eye, Insanity, and Vaccination can be specially studied.

Perpetual Fee to all the Lectures, 44 guineas.

The Laboratories, Libraries, and Museums are open daily.

Medical Scholarships in the University:—Four Scholarships of £25 a year, each tenable for four years by Students residing at Durham or Newcastle, and not of sufficient standing to proceed to a License in Medicine. A Scholarship will be awarded in October next.

Dickinson Memorial Scholarship, viz., £15 for general proficiency.

At the end of each Session a Silver Medal and Certificate of Honour will be awarded, after examination, to the best Student in each class.

By a recent Act of Convocation, the terms necessary for Degrees in Medicine and Surgery may now be kept by residence either at Durham or Newcastle.

LUKE ARMSTRONG, L.R.C.P., Registrar.
W. CHA. ARNISON, M.D., Secretary.

Newcastle-upon-Tyne, August 1870.

LABELS CUT BY MACHINERY.

ADHESIVE FOR MARKING GOODS, 1s. per 1000: Dispensing or Chemical, 2d. per 100, kept in stock; with Name and Address, 2s. per 1000; Mixture, Pills, &c., equally moderate. An assortment of Labels of all trades. Contracts with large consumers.

J. CROSS AND SON, Engravers, Steam Machine Printers, Lithographers and Stationers, 18 Holborn-Hill, E.C.—Established 1813.

St. GEORGE'S HOSPITAL MEDICAL SCHOOL.

THE WINTER SESSION will commence on MONDAY, 3rd OCTOBER, with an Introductory Address by Mr. BRODHURST, at 2 p.m., in the Hospital.

Consulting-Physicians.—Dr. Wilson, Dr. Bence Jones, Dr. Pitman.
Physicians.—Dr. Fuller, Dr. Barclay, Dr. John Ogle, Dr. Wadham.
Assistant-Physicians.—Dr. Dickinson, Dr. William Ogle.
Physician-Accoucheur.—Dr. John Clarke.
Consulting-Surgeons.—Mr. Cæsar Hawkins, Mr. Cutler, Mr. Tatum.
Surgeons.—Mr. Hewett, Mr. Pollock, Mr. Henry Lee, Mr. Holmes.
Assistant-Surgeons.—Mr. Rouse, Mr. Pick.
Ophthalmic Surgeon—
Orthopædic Surgeon—Mr. Brodhurst.

A Maternity Department and Departments for Ophthalmic and Dental Surgery are arranged in connexion with the Hospital School.

LECTURERS.

Descriptive and Surgical Anatomy	Mr. Rouse.
Physiology and General Anatomy	Dr. Wm. Ogle.
Chemistry	Dr. Noad, F.R.S.
Medicine	Dr. Barclay.
Psychological Medicine	Dr. Blandford.
Surgery	Mr. Holmes.
Ophthalmic Surgery	
Orthopædic Surgery	Mr. Brodhurst.
Operative Surgery	Mr. Rouse.
Pathology and Morbid Anatomy	Dr. John Ogle.
Midwifery	Dr John Clarke.
Materia Medica	Dr. Dickinson.
Forensic Medicine	Dr. Wadham.
Dental Surgery	Mr. Vasey.
Botany	Mr. Child, F.L.S.
Comparative Anatomy	Dr. Cavafy.

Clinical Lectures by the Physicians and Surgeons every week.

A Medical Tutor is appointed to superintend the studies of the pupils, and hold periodical examinations.

On payment of one hundred guineas at entrance, a Pupil becomes perpetual to the Hospital Practice and all the Lectures.

Compounders pay forty guineas on admission, forty guineas for the second year, and ten guineas for each subsequent year, until their payments shall have reached one hundred and ten guineas, when they become Perpetual Pupils.

Gentlemen may enter separately to Medical or Surgical Practice, or to any single course of Lectures.

Dental Pupils are admitted on payment of £45.

The Pupils attending the Practice of the Hospital will be divided into classes among the Physicians and Surgeons in rotation, and each of them will be required to act as Clinical Clerks and Dressers to the Medical Officer to whom they are attached.

Special Demonstrations of Skin Diseases and Lectures on Public Health will form part of the course of Lectures on the Practice of Medicine; and Students will be required also to attend the separate courses of Lectures on Pathology and Psychological Medicine.

In connexion with the Lectures on Surgery, Demonstrations will be given on the use of the Laryngoscope. A separate course of Lectures on Diseases of the Eye, with Demonstrations of the use of the Ophthalmoscope, will be given, as well as Lectures on Orthopædic Surgery, with Illustrations of Deformities and their Treatment. Attendance on each of these courses will be required of Surgical Pupils.

In the Maternity Department, special Clinical Instruction will be given on Diseases peculiar to Women, and Practical Instruction in Vaccination to those who require certificates of proficiency.

House-Physicians and House-Surgeons are selected from among the senior Students according to merit, without further payment beyond a small sum paid to the Hospital for board.

The offices of Obstetric Assistant, Curator of the Museum, Medical and Surgical Registrars, and Demonstrator of Anatomy, with salaries of from £50 to £100 attached to each, are held out for competition annually. The William Brown Exhibition of £40 per annum, tenable for three years, is bestowed after a competitive examination. Clinical Prizes are offered annually by Sir Benjamin Brodie and Dr. Acland. Sir Charles Clarke's "Good Conduct" Prize, the Thompson Medal, and the Johnson Memorial Prize are also to be competed for each year. A general examination of all the Students is held at the end of the Summer Session, and Prizes and Certificates of General Proficiency are given to the most deserving.

Further information may be obtained from Dr. Barclay, the Treasurer, or Dr. Wadham, and from any of the Lecturers and Medical Officers of the Hospital.

GLASGOW. ANDERSON'S UNIVERSITY.

THE MEDICAL SESSION will be opened on TUESDAY, the 25th OCTOBER, 1870. The SUMMER SESSION on the FIRST TUESDAY of MAY.

Anatomy	Professor George Buchanan, M.D.
Chemistry	Professor Thorpe, Ph.D.
Institutes of Medicine (Physiology)	Professor Eben Watson, M.D.
Materia Medica	Professor Morton, M.D.
Surgery	Professor Dunlop, M.D.
Practice of Medicine	Professor M'Call Anderson, M.D.
Midwifery (In Summer)	Professor J. Gurlson, M.D.
Medical Jurisprudence (do.)	Professor P. A. Simpson, M.D.
Ophthalmic Medicine & Surgery	Dr. Wolfe.

Fee for each Course of Lectures, £2 2s.

A Syllabus, with full particulars, may be obtained from the Janitor, at 204 George Street, or from

ARTHUR FORBES, Solicitor, 146 Buchanan Street,
Clerk to the Medical Faculty of Anderson's University.

LIMERICK UNION

THE CASE OF DR. PORTER, CASTLECONNELL.

The Clerk announced that he had received a sealed order from the Commissioners, which he read, dismissing Dr. Frank Thorpe Porter from the office of Medical Dispensary Officer for Castleconnel and Annacotty.

Dr. O'Sullivan said he would wish to be informed whether a sworn investigation was asked for into the charge preferred against Dr. Porter, and whether it was refused. He had been told by one member of the committee of management that such was the fact, and by another that it had not been asked for.

Mr. Gabbett said he would very shortly give them what occurred. There was a meeting of the committee of management held by the directions of the Poor-law Commissioners, to pass their observations on a report which was furnished to them by Dr. Porter. As secretary of the committee, he furnished Dr. Porter with a copy of the resolution, and in reply to the proposition made in it, he received a letter from Dr. Porter in which he declined to accede to the request expressed in the resolution, namely, that he would resign his situation as Dispensary Officer for Castleconnel and Annacotty. In the letter, Dr. Porter said, "I wish for an investigation; but hope that my accusers will not be my judges," or words to that effect. Commissioners wrote to Dr. Porter requiring his explanation on the subject. He wrote a letter back to them which they did not deem satisfactory, because he (the secretary) shortly afterwards received a letter enclosing the sealed order for his dismissal.

Alderman Tinsly said he wished to supply one link in the statement Mr. Gabbet had made. Dr. Porter, in the letter, as he was accused of a criminal offence, asked the Commissioners for a copy of the letters which he was charged with having written, and that when he received them he would give the explanation, and not until then. The Commissioners replied to that letter by saying that Dr. Porter's asking for a copy of the letters was an aggravation of the offence, and that they would not supply a copy of the letter.

Mr. Gabbett.—And they gave it as their opinion, too, that he was the writer of the anonymous letter. He (Mr. Gabbett) said that the question was merely between the Poor-law Commissioners and Dr. Porter, and it was not a matter to be interfered in by the Board of Guardians.

Alderman Tinsly said Mr. Gabbett had made an addition to what he had stated,—namely, that the Commissioners had expressed their opinion that Dr. Porter was the writer of the anonymous letter. What right had the Commissioners to say such a thing when they had no proof that he did write it, and when they would not give him an opportunity of defending himself? (Hear, hear.) Several members of the committee stated their opinions that the act of the Commissioners in the matter was very arbitrary. They also stated that no matter what was the rank of a man in life, he had a right—a perfect right—to be allowed to defend himself from any charge preferred against him, and had a right to get a trial. What Dr. Porter, and what he, as an independent member of that board and of the dispensary committee, complained of was, that he was not allowed an opportunity to defend himself from the charges preferred against him. Dr. Porter should be presumed to be innocent until he had been found guilty; but that was not done, and the strongest censure the Commissioners could pass upon him—a censure which would deprive him of being able to earn his bread as a professional man, was passed upon him—the censure of dismissing him by sealed order. At the end of the meeting an anonymous letter was produced by one of the members, and it was stated to have been written by Dr. Porter. The doctor was then present; and when that letter was produced he became most excited, and in a very warm manner repudiated in the strongest terms that he either wrote the letter, or induced any one to write it, or that he knew anything at all about it. He became so excited that the chairman requested him to leave the room, and he did so. During his absence from the room, the majority of the members present passed a resolution calling on the Commissioner to call on Dr. Porter for his resignation of the office he held. Before the meeting of the committee broke up on that day, he (Alderman Tinsley) expressed it as his opinion that they were acting prematurely in expressing their opinion on that day, and he proposed that they should adjourn the consideration of the subject for one week, in order to give an opportunity to Dr. Porter to defend himself. That proposition was rejected, and they would not give one hour to him, but passed a resolution calling upon him to resign. That was extremely harsh (hear, hear). It was quite out of the question, even if he were innocent, as he (Alderman Tinsly) believed he was, it would be quite impossible for him to maintain his position in the Castleconnell Dispensary District.

Mr. Browne defended the conduct of the committee in acting in the manner in which they did, and said that in reference to the annonymous letter, when it was produced and compared with one written by Dr. Porter, there was not a member of the committee who had the slightest doubt that they had not been written by the same hand.

Alderman Tinsly.—I was there and did not believe they were written by the same hand.

Mr. Laffan.—Neither did I.

Mr. Browne referred to the fact that when the letter was produced, and before a word had been said of what it contained, or who wrote it, Dr. Porter stood up, and declared he never wrote the letter.

Dr. O'Sullivan again, when Mr. Browne had concluded, asked for an answer to his question, whether the investigation had been asked for, and was refused?

The Chairman said there was no doubt but it was asked for and refused.

Dr. O'Sullivan proposed that the Commissioners should be called upon to hold a sworn investigation.

The resolution, which was seconded by Mr. Cronin, was

subsequently withdrawn, it having been proposed by Mr. Browne, and seconded by Mr. Laffan, two members of the committee, that the Commissioners be requested to withdraw the sealed order, and that Dr. Porter be allowed the option of resigning the situation.

This was agreed to unanimously, and the Board soon after adjourned.

THE DISMISSAL OF DR. PORTER.

The Chairman read a communication from the Commissioners, in reply to a resolution of the Board, requesting them to withdraw their sealed order dismissing Dr. Porter from the Castleconnel dispensary, stating that in consequence of the offensive character of his letters, they thought it right to remove him, and would, therefore, decline to accede to the request of the guardians. His removal would not, however, as the guardians feared, deprive him of a situation in future under the Poor-law Commissioners, but his future appointment would be subject to their approval, and they did not think that such appointment was probable.

After discussion, in which Messrs. Hosford, Cronin, Cregan, and Sampson denounced the conduct of the Commissioners,

On the motion of Mr. Cronin, seconded by Dr. O'Sullivan, it was agreed that the Commissioners request the committee to furnish the Board with all letters and correspondence on the subject.

It was resolved, on the motion of Mr. Cregan, seconded by Alderman Tinsley, that the Board consider the correspondence already received from the Commissioners incomplete, and that they had no doubt the grounds on which they dismissed Dr. Porter were insufficient.

The Board soon after adjourned.

BELFAST BOARD OF GUARDIANS.—Tuesday.

The clerk read the following letter :—

"Poor-law Commission Office, Dublin,
"29th August, 1870.

"Sir,—The Commissioners for Administering the Laws for the Relief of the Poor in Ireland desire to acquaint you, for the information of the Board of Guardians of Belfast Union, that, Dr. Knox having resigned the office of Poor-law and Medical Inspector, the union has been placed under the charge of Mr. O'Brien.

"By order of the Commissioners,
B. Banks, Chief Clerk.

"To the Clerk of Belfast Union."

Mr. Teirney proposed the following resolution :—"That we cannot allow this opportunity to pass without conveying our unanimous vote of thanks and respect to Dr. Knox for the kind manner in which he performed his duties towards the deserving poor of the union, and in seeing that the Laws of the Relief of the Poor were mercifully administered by the guardians of this union during his term of office ; also for his uniform urbanity and gentlemanly conduct towards all the guardians connected with the board."

Mr. Gaffikin seconded the resolution, which was unanimously agreed to. The remaining business was routine.

MALLOW UNION.—Friday.

Mr. Hutch proposed that the salaries of the medical officers of the Buttevant dispensary district be increased from £70 to £100 a year each. He said that in that district the population amounted to 8,551, and the number of tickets issued during the past year was 2,171, while the salaries of the two medical officers amounted to but £140 a year. In the Ballyclogh district the population was 3,122, and the number of tickets issued in 1869 was 741, yet in that district the medical officer had £100 a year. In Rahan, too, the medical officer had £100 a year, while the number of tickets issued there during the past year was but 479. The same state of things prevailed in other districts, which showed that infinitely more work was done by the medical officers of the Buttevant district than by the others, and yet the former had but £70 a year each while the latter had £100. He considered that the Buttevant physicians were well entiled to the same salary, and he had much pleasure in moving that their salaries be increased to £100 a year. (Hear, hear.)

Mr. Moriarty seconded the proposition, and it was evident there was a necessity for two medical officers in the Buttevant district or else they would not be placed there, and when it was necessary to have them they should be kept in a suitable position. (Hear, hear.) He considered that £100 a year was the lowest salary that could be paid them, and where the increase was recommended by the local committee, who were the best judges in the matter, he thought the Board should unanimously grant the increase. (Hear, hear.)

Mr. Purcell said he should on principle oppose the proposition. He had not the smallest word to say against the ability, efficiency, or activity of the medical officers in question, but he thought the guardians ought to exercise every means of economy towards the ratepayers. (Hear, hear.) He did not see any ground for raising the salaries. There were two gentlemen in the Buttevant district to discharge duties which in other districts quite as large were efficiently done by one. (Hear, hear.) Therefore, he saw no just grounds for the increase, and he believed if the situations were vacant to-morrow there would be plenty of men competing for them. (Hear, hear.) The fact was the raising of salaries was becoming too common in all unions (hear, hear) ; but he thought the officers holding the situations should resign, and then if good men could not be got to do the duties at the salary let it be raised. (Hear, hear.)

Mr. Green said that when the other doctors salaries were raised they were not called on to resign. (Hear.)

Mr. Barry said that lately additional work had been imposed on the medical officers in Buttevant, and that was a fact that ought to be taken into consideration. (Hear.)

Mr. Magarth, while objecting to the increase asked, would not object to pay something additional for the increased duties thrown on the medical officers.

Mr. Purcell moved as an amendment, that the gentlemen be called on to resign before the question of increasing their salaries was entertained. (Hear, and no, no).

No one seconded this.

The Chairman said that the argument put forward in favour of the Proposition was, that the medical officers of the Buttevant district had more work to do than those in other districts, which at first sight had a very plausible appearance, but to his mind it was conclusive against the proposition, for not only was the work in the Buttevant district greater than in any other district of the union, but it was greater than in any other similar district in Ireland. The conclusion he arrived at was, that there was an unwarrantable amount of tickets issued there, and that the relief was most indiscriminate and unjustifiable. (Hear, and no.)

Mr. Hutch said that in the Mallow district the population was less than in Buttevant, yet the number of tickets issued was almost the same. (Hear).

The Chairman said the amount of medical relief given in Buttevant was enormous, and as an amendment he would move that it was hoped the Commissioners would not sanction any increase of salary to the Buttevant medical officers until it was satisfactorily explained that the comparatively enormous issue of tickets there, involving as it did increased and most probably superfluous duties on the part of the medical officers, did not itself constitute a very grave abuse requiring reform.

Mr. Williamson seconded the amendment.

Mr. Green, Mr. Moriarity, and other Guardians protested against such an amendment, as it involved a charge against the Buttevant Dispensary Committee.

The Chairman said he made no charge, but his belief was there was an unwarrantable issue of tickets in Buttevant.

Mr. Hutch said that such an amendment was an insult to the committee.

The Chairman modified his amendment, and then put it to the Board, when it was rejected without a division.

Mr. Magarth then moved as an amendment that an increase of £15 a year be granted to each of the two medical officers.

Mr. Barry seconded this, but it was rejected also.

A conversation ensued, after whibh Mr. Hutch withdrew his proposition, and a division was taken as to whether the increase should be £15 or £20 a year to each officer. For £15 there appeared seven votes, and for £20 ten. The latter was accordingly carried by a majority of three.—Adjourned.

CLONMEL UNION—Thursday.

CHOLERAIC DISEASE.

The following letter was read :—

"Clonmell, August 24, 1870.

"Sir—I think it my duty to inform the Board of Guardians that, for the last ten days, there have been a great many cases of choleraic diarrhœa, with some very decided cases of cholera, one of which died in Mall lane ; he came to Clonmell from Carrick-on-Suir, very ill. Another has been sent into a cholera ward in the fever hospital. I would suggest that there was an action taken at once in the matter. If there be any increase in the disease, it would be perfectly impossible for me, single-handed, to attend to all the cases, as it is, I have worked rather too much. They should be compelled to go into hospital, and a proper mode of conveyance for their transmission provided ; and there should be a thorough cleansing and whitewashing wherever those cases occur.—I have the honour to be, Sir, your obedient servant,

"P. Fitzgibbon."

The Chairman said he had the authority of Dr. Gitzgibbon for stating that he never saw the lanes of Clonmell better attended as to whitewashing and cleanliness. His (Mayor's) instructions to the Corporate Inspector was, to carry out whatever directions he received from the Doctor, as to whitewashing, &c., wherever sickness occurred. Dr. Fitzgibbon requested him to mention that the vehicle used for the conveyance of patients to the hospital was not suitable, and he recommended that a kind of ambulance waggon should be procured, in which patients could lie down.

Dr. Scully said it would be quite dangerous to leave such patient on a seat for ten minutes.

Mr. Davis should think there ought to be something done for the town, independent of any action of the Board of Guardians. Within the borough the Guardians had no authority.

The Chairman said there was no sanitary board within the borough, so that the Guardians where the proper authority.

Dr. Cantwell said that the Guardians had control outside the borough, but, inside, the Corporation was the authority. Mr. Cantwell here said that he was very sorry to be obliged to bring before the board, for the third time, a terrible nuisance that existed on the Cahir road ; and if some steps were not now taken, he would communicate with the Commissioners direct. There had been a habit of throwing dead horses into the old quarry at Tubberaheena ; but latterly they had left the carcases at the quarry at the top of the hill. This morning two were there exposed, and the stench from them was fearful. It was the duty of the Board, he thought, to take immediate action in the matter.

The Chairman said the remedy was very plain and simple. The parties who created the nuisance should be summoned ; the place was outside his jurisdiction.

Mr. M'Eniery—If the stench is so terrible, how is it that the other magistrates don't get it ?

Mr. Cantwell—If you doubt what I say, Mr. M'Eniery, you can go out yourself to the place and take a smell (laughter).

The Mayor said that the Constabulary had power to prevent this nuisance. No person could act as knacker without a license.

Mr. Cantwell observed that he had brought the matter under the notice of the police, and they certainly did what they could.

After some discussion, it was decided that the clerk should communicate with the police authorities.

The discussion of Dr. Fitzgibbon's letter was resumed by

Mr. Davis, who said they should take it step by step. One of the first things to be done, according to a circular from the Commissioners in 1866, was, when they receive a communication announcing the existence of cholera, to issue notices according to a form prescribed, setting forth the situation of the dispensary ; and that when persons suffered from diarrhœa, they should at once go for medical advice, which they could have without any ticket. The Guardians ought also at once decide on a ward in the hospital for cholera patients.

Dr. Scully said that the one case admitted was now convalescent. He told Dr. Fitzgibbon that he would receive in hospital any cases of cholera sent there, and attend to them.

The Chairman would not recommend the posting of the notices suggeted in the Commissioner's letter, referred to by Mr. Davis, as doing so would only create alarm.

Mr. Cantwell, as to assistance for Dr. Fitzgibbon, referred to the fact that in 1866, when there we similar reports to the present, Mr. Ward was appointed inspector of nuisances. He thought a similar course might be adopted now.

Mr. Riall—It would not help us one iota.

Mr. Davis.—If Mr. Ward were a medical man he might help us, but he is not. The relieving officer has a very simple duty to perform ; he need not wait for authority from the Board to get houses whitewashed and cleansed where necessary.

The Chairman said if there was likely to be a continuance of the disease they might get assistance for Dr. Gitzgibbon, but there was nothing to prevent them waiting for a week. The town was in a very satisfactory condition, except as to water, as two or three pumps had lately run dry.

A minute was drawn up stating what course the Guardians were prepared to adopt, and the master was directed to go to the Artillery Barracks in order to see an ambulance waggon with a view of having one constructed.

DUNDRUM DISPENSARY.

Superannuation Allowance to Dr. Bernard.—At the last meeting of the Rathdown Board of Guardians, it was moved by Emanuel James Bayly, J.P., seconded by General Hall, C.B., that "Recognizing the long and meritorious services of Dr. Bernard, late medical officer of the Dundrum portion of the Dundrum and Glencullen Dispensary District, thirty-one years in the Dundrum, and four years in the Glencullen portion of the district, and that in the exercise of his duties he has contracted a permanent infirmity which altogether incapacitates him from the efficient performance of the duties of medical officer. This Board concurs in the resolution of the Dundrum and Glencullen Dispensary Committee assembled at the extraordinary meeting on the 18th July, and unanimously agreed to, 'That the highest amount of superannuation allowance be recommended for Dr. Bernard, and request that the Commissiondrs will sanction the same.'" The motion was carried unanimously, and £60 per annum voted.

NORTH DUBLIN UNION.

Mr. Wm. L. Ensor has given notice "that on Wednesday the 14th September he will propose that the salaries of the medical officers, visiting and resident, of the North City District, shall be increased by £25 per annum."

Mr. Franklin gave notice "that on this day fortnight he shall move that the doctors' salary of the rural district of the North Dublin Union be increased £25 per annum."

After the disposal of some routine business, the Board adjourned.

Poor Law Inquiry.—An investigation was opened on Friday last at the Kildorry Hospital, County Cork, by William O'Brien, Esq., Poor-Law Inspector, into charges preferred against Dr. William H. Rogers, the physician of the dispensary, by several inhabitants of the district. These people were examined at great length, and, if the report of their evidence in the local papers be correct, they charged the doctor with the habitual use of abusive language to them when they sought his professional help, negligence in attending to them, and intoxication. It was elicited from most of the witnesses or complainants, on cross-examination, that the circumstances of which they complained took place as long as two years since, and that they would not have made any complaint of Dr. Rogers if their priest, the Rev. Mr. Riordan, had not advised them to do so. Captain Bowen bore testimony to Dr. Rogers' urbanity and attention to his duties. The inqury has terminated, but no action has yet been taken by the Commissioners thereon.

THE HIGH-HANDED COMMISSIONERS OF POOR LAWS.

It is now quite certain that the three gentlemen who sit in the Custom House, Dublin, and regulate the affairs connected with the administration of the Poor Laws in Ireland, are determined to carry matters with a high hand in relation to the Castleconnell Dispensary district. They have sent a letter, we understand, to the authorities, stating their determination to adhere to their sealed order dismissing Dr. F. T. Porter from his position as resident medical officer; and the letter has been received this morning. We need not say that the arbitrary course taken by the Commissioners has caused universal pain, dissatisfaction, and disgust. Even if Dr. Porter were guilty of the act imputed to him—that of writing an anonymous letter to a member of the Committee, is it impossible to find something like a parallel case not far from home? Surely our readers must have exceedingly short memories if they be not aware of the facts to which we refer, and of the reward, not the degradation, which has resulted. We do not propose to vindicate Dr. Porter, but we do protest loudly—emphatically—and in the spirit of even-handed justice, against the course that has been adopted in his regard. It is doubtful if the course be legal; and in the interests of persons who hold offices under the Poor-law, as well as in the interest of Dr. Porter, the legality or illegality of the extremely arbitrary steps taken by the Commissioners against him ought to be tested in a court of law, in order that it should be ascertained above board whether the course in question is consistent with law—we do not add with fair play. We do not believe that that course is in accordance with the spirit of the Constitution; and it is due to those who have given a consistent and unbiased support to Dr. Porter to see that in this case at least the powers which the Commissioners assume should be legally tried before the competent tribunal, and in a manner which will develope the facts in all their fulness on every side. What Dr. Porter's opinions in the matter are we do not know; but we do know the opinions of all those who are independent of the adverse influences which have prevailed against him; and these opinions are decided, strong, and earnest. Even the Dispensary Committee became remorseful and repentant when they witnessed the severe usage to which the sealed order without a trial subjected him; and the Board of Guardians unanimously agreed to request the Commissioners to withdraw the summary dismissal, and permit Dr. Porter to resign a situation which it is obvious he could not hold in the face of a strong and persistent opposition. If tenure depends on so slender a thread as the dictum of the Commissioners, the sooner the law is changed the better.—*Limerick Reporter.*

We have over and over again endorsed in anticipation the foregoing observations, and though well aware of the futility of our doing so, we continue to protest against the arbitrary nature of the powers wielded by the Commissioners. Whether Dr. Porter did or did not commit the fault attributed to him, or did or did not deserve dismissal, is nothing to us. The Commissioners are as little in a position to decide the question as we are, for they have never taken the trouble to inquire, by any of the means at their disposal, which justice requires that they should avail themselves of.

Their inspector did, in point of fact, investigate prior accusations, and did practically acquit Dr. Porter, and now the Commissioners have dismissed him, not because he has been proved to have neglected his duty or disregarded his instructions, not because a clique in his Dispensary Committee have a dislike to him and accuse him of a fault which there is not the least public reason to believe he ever committed. While we freely acknowledge the general impartiality of the Commissioners in their arbitration between doctors and their taskmasters, we repeat that neither they nor any other persons should be invested with absolute and irresponsible power, which from time to time, as in the case of Dr. Wright, of Acklow, they have been betrayed by the whisperings of influential persons into using without warrant of justice.

Fruit.—We believe the quality and quantity of the fruit crop is above an average this year. We learn the plum trees are laden, and that in most places they are to be obtained in profusion at a very cheap price. Apples, it appears, are very abundant, but in this they are equalled by pears which are to be seen hanging very thickly "on walls, pyramids, espaliers, and standards." Other fruits are also plentiful, as apricots, peaches, and nectarines; but we confine ourselves to those kinds which are most consumed by the public. Good ripe plums we consider nutritious, but they should be always consumed after meals. We have known them produce a very severe and intractable form of diarrhœa. Apples, unless very ripe, should be baked. The number of cases of diarrhœa in children, induced by eating green, acrid, and hard apples, is, weekly, very great. We agree with a writer in *The Field* who deplores that pears are not more extensively used as an article of diet; for he considers, and we see nothing against it, that good young, ripe pears eaten with bread ought to be most pleasant and healthful; when they are not ripe we recommend them to be stewed, when, if eaten with bread, they not only make a pleasant meal, but prove exceedingly nutritious. It is to be regretted that fruits are more viewed in the light of extras, and partaken of at improper times. If fruit be good, gathered fresh, ripe, and free from rot or insects, eaten with care and prudence, it will be healthful. After six o'clock in the evening, no fruit should be eaten, owing to returning chilly evenings, the stomach is slow to digest cold, acid articles of diet, so that the earlier time of the day will be found safest. A little fruit by way of *dessert* after a hearty dinner is an exception to the rules we enforce.

The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 14, 1870.

STUDENTS' NUMBER.

WE have always felt that the information necessary for the guidance of the expectant Student in Medicine or his guardian is embodied only in very unsatisfactory and insufficient form in Official Regulations, which, when desired, are always at command. We have, therefore, accorded to such matter the smallest possible space consistent with clearness, confining our erasures as much as possible to technical redundancies, and omitting from them nothing which seemed of the least importance.

Into the space which this epitomizing has given us, we have endeavoured to compress as much practical, everyday information as we conceive to be necessary, and writing as we do for the Students of the United Kingdom, and not solely for London, we have endeavoured to give predominance to the educational arrangements of no special locality.

THE CAREER OF THE ENGLISH STUDENT.

THE young gentleman who is about to enter the Medical Profession in England has more than one course open to him, whether he decide on fulfilling his curriculum in London or in one of the provincial schools. The latter course is generally determined by local causes with which pupil and parent are both familiar. We propose, therefore, in this place, to point out a few things that concern alike the London or provincial medical student.

First of all, as to apprenticeship. The only English corporation that absolutely requires an apprenticeship is the Society of Apothecaries, which is bound by Act of Parliament. The clause, however, is very liberally interpreted, and the apprentice may, during his term, fulfil part or the whole of the curriculum. The master must possess the licence of the Company, but he may practise any department of the Profession. There is much difference of opinion as to the value of an apprenticeship. Some profess to despise it, and regard it as a badge of trade. There are, however, many advantages in the system, if carried out in the liberal mode we have spoken of; and we feel sure neither pupil nor parent would ever regret having entered into such an agreement with a medical gentleman of position and honour. Thus, suppose a pupil to be bound apprentice to a Licentiate of the Apothecaries' Company for a period of five years, with the right to attend lectures and hospital practice during the last three years, he enjoys the following advantages: In the early part of his pupilage he not only learns practical pharmacy, and becomes acquainted with the more generally used articles of the Materia Medica, but may be assisted in preparing for the Preliminary Examination. Moreover, he prepares himself to take, should he ever wish to do so, the post of assistant to a general practitioner, as the experience he has thus acquired will procure him a situation in preference to prizes, gold medals, and even university distinctions. Again, this experience is of the very highest value, should he decide on settling in general practice after he is qualified. On the whole, then, this modified apprenticeship system is equal to any, and parents who know a practitioner to whom they would willingly entrust their sons, cannot do better than pay him a fair premium. Those residing near will occasionally be able to arrange for an out-door apprenticeship.

Supposing, on the other hand, that the plan of apprenticeship be rejected, a young man may still become the pupil of some one in practice. This is often done by those who aim at the higher branches of practice. A physician or surgeon who will give some time to the superintendence and direction of a pupil's study certainly offers him great advantages, and those who can afford thus to act will not regret the expense of providing their sons with such a guide.

Lastly, a pupil may enter at any of the London hospitals without any such preparation. He has only, provided he has passed a preliminary examination, to pay the first year's fees, and he is admitted at once to all the dignity of a medical student. He should decide on the diplomas he requires, and guide his studies accordingly. Most of the schools now have a composition fee, entitling to all required for the ordinary qualifications in medicine and surgery. They also mostly have another sum, very little higher, entitling the student to perpetual attendance on all lectures and hospital practice. It is better to take out the perpetual ticket, as all contingencies are thereby provided for. The fees are mostly payable in two or three instalments, at the commencement of each Winter Session. The Dean will always forward details, as well as any special information of which a student may find himself in need. The first instalment varies from forty to fifty guineas; the second is a like sum; the third usually only makes the whole paid a hundred guineas or a little over.

The student who comes from the country to enter in London not unfrequently requires lodgings. Those who can live with relatives and friends are, of course, best suited; but not a few find themselves very comfortable in furnished apartments, which are to be had in respectable streets near all the hospitals. Two brothers or two friends can, of course, do this a little less expensively than one. We have known a good sitting-room and bed-room hired for the Session at half a guinea a week. The price varies

with the season a little, and some can afford more than others, and therefore can always have a selection of better rooms.

Residence settled, student life begins on the 1st of October, by hearing the Introductory Lecture, at the conclusion of which the fees may be paid, unless they have already been handed over.

It should be mentioned that one or two of the medical schools have collegiate institutions in connection with them, where rooms may be had instead of the more usual plan of taking lodgings. Some of the lecturers at most schools receive pupils, and all of them will at any time afford special information to those who may inquire of them. It is therefore a good plan to communicate with any one of them with whom the intending pupil or his parents may have any acquaintance, or to whom an introduction can be obtained. Or, in any case, the Dean will at once reply to inquiries by post and forward a full prospectus.

As to contending for prizes, there are differences of opinion. Diligent attendance on the classes and in the wards will enable the student to store his mind with knowledge fitting him for his profession, and this should be his first aim. Gold and silver medals are honourable distinctions, but only secondary ones. We never competed for them, nor encouraged others; and some of the most eminent men hold the same views. Others, however, differ from us, and the pupil may judge for himself. Competition for appointments to dresserships and other offices, where much practice is seen, stands on a different footing. No prize can equal such posts; and the possibility of getting them should influence largely the choice of a school. In some schools they must be paid for. In others, the diligent gain them without extra expense. The student, having selected his hospital and school, has chosen his teachers. We have only to remind him that however able they may be, the result depends on his own application. Let him supplement their efforts by giving all his energy to the pursuit of knowledge, and there is not one of our schools of medicine in which he will not acquire such a knowledge of his profession, that when the time comes he will pass his examination with ease, and, what is more important still, will then be able to practise in our noble profession with benefit to the sick to whom he may minister.

The information most important to students may be divided into two parts—first, the regulations with which they must comply before they can present themselves for examination to any of the Licensing Bodies; second, the means that exist to enable them to do so. In the first category are to be placed the regulations of the Corporations; in the second, some account of the many Schools of Medicine and Hospitals where professional education can be pursued. A natural supplement to this information is a brief sketch of the career open to young men after they have obtained their diplomas, especially in the Public Services. Hence we furnish some particulars that will be interesting to those who contemplate entering the Army or Navy, or taking service under the Poor-law Board.

According to this plan, we proceed to consider, first of all, the regulations of the Qualifying Bodies.

Treatment of Hæmatemesis.

In the same report it is stated that alum whey is very effectual in hæmatemesis in cases of perforating ulcer of the stomach.

THE UNIVERSITIES.

Oxford and Cambridge.—The elder English Universities have of late years opened their doors much wider than heretofore, and that without losing any of the prestige they possessed. Those who propose to follow their course of education need not any longer enter at any particular College or Hall, although it will probably be long before lodger students will be very numerous. There are advantages in the College life that will not be willingly given up by those who can afford it, and, for a purely medical career, it would be perhaps preferable for those who would not like to enter a College to graduate at the London University.

We would here urge upon every student who may enter any University the great advantages they would derive from a course of study in the Faculty of Arts, and we strongly advise every one who has the time to take a Degree in Arts before commencing his medical curriculum. A Degree in Arts stamps a man for life; and as some examination must be passed before the commencement of professional study, it would always be best to take such a degree. A University Degree in Arts is recognized universally as the preliminary examination, and possesses its own value, besides exempting from other tests.

University of London.—The medical degrees of this University have now obtained a reputation second to none, and no student can therefore propose to himself a higher qualification. The training is rather longer than that required for the diplomas of most of the corporations. The examinations are very stringent, and it is in after years that the student will feel the gratification of having obtained such a degree. Every student is required to go through the full course of hospital studies *after* he has passed the matriculation examination. It is, therefore, very desirable he should matriculate before entering a medical school, otherwise two years will be lost. The matriculation examination of this University is accepted as a preliminary by the Medical Council, and therefore the labour bestowed in preparation will serve the student's purpose even if he do not proceed to a degree. The medical degrees of the University are Bachelor and Doctor of Medicine, and Bachelor and Master in Surgery. Degrees of Bachelor and Doctor of Science are also now obtainable. There are, at each stage of the graduate's career, examinations for honours, which afford the student the opportunity of gaining highly-prized distinctions in various branches. There are also scholarships for the most successful.

University of Durham.—The degrees of Bachelor and Doctor of Medicine are granted by this University, as is also the degree of Master of Surgery. There is also a licence in medicine, to obtain which residence is not essential. A licentiate cannot pass to the M.B. until he has obtained the degree of B.A., or passed an equivalent examination. Only M.B.'s of twenty-one terms' standing can proceed to M.D.

There is a medical scholarship of £25 tenable for four years, and the fees, both Collegiate and University, are very moderate.

THE CORPORATIONS.

From the Universities we pass to the other bodies that can give authority to practise.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

THE FELLOWSHIP.

The Fellowship is only attainable by election. No one can be proposed who is not a Member of four years' standing. The mode of election has long given much dissatisfaction, as the readers of The Medical Press and Cir-

CULAR are well aware. There is a general admission as to the justice of our strictures, and from the liberal feeling of the majority of the Fellows, a reform has already been initiated, which is sure to bear good fruit.

THE MEMBERSHIP.

A person may become a Member of this College without holding a degree in Medicine, or indeed any other diploma. This is not very often done; for the Membership gives no right to the use of the title doctor, though some Members not possessed of a degree do so style themselves. This is, however, in direct violation of the rules of the College to which a Member pledges himself on admission. The curriculum extends over four years.

Graduates in Medicine of any British University are admitted to an examination for the Membership. Such graduates are exempt from some parts of the examination —*e.g.*, anatomy and physiology. Even foreign graduates of accredited Universities have no difficulty in being admitted to examination.

THE LICENCE.

This diploma authorizes the holder to practise his Profession as a Licentiate of the College. Unless a graduate of some University, he is forbidden to use the title of doctor, but we regret to say many do so. At first it was regarded as a medical diploma for the general practitioner, intended to supersede that of the Apothecaries' Company. The examination is conducted by specially appointed examiners, and is complete in the several departments. It has been proposed to give this licence to Licentiates of the Apothecaries' Company, on payment of a fee, *without examination*.

Not quite two years ago we had to record the most important change that has ever occurred in reference to the qualifications of general practitioners. This licence of the London College of Physicians was then recognized by the Poor-law Board as a qualification in surgery as well as medicine. Consequently, this single diploma is sufficient to enable any one to take a Poor-law appointment. It ought, therefore, to become a single authority to practise every department of the Profession. In such case, any one contented with the diploma of L.R.C.P. Lond., would have all he needed, and the one faculty system so long desired by earnest reformers would be established.

It is to be supposed that the College will follow up its advantage, and protect all its Licentiates in the exercise of all branches of the Art of Healing.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

No Corporation has exercised so great an influence over the Profession in England as this. Without the M.R.C.S. it is not easy to obtain any English surgical appointment. In a parish appointment, its membership, though no longer essential, carries great weight. Hence, most English students intend to prepare themselves for this, which, together with a medical qualification, suffices for every purpose of the general practitioner. The College has two grades, Member and Fellow. It also gives a diploma in midwifery, but this is mostly confined to those who are already Members.

THE FELLOWSHIP.

Members of long standing can be admitted by election. As, however, this grade is also obtainable by examination, this is the more usual mode. Consulting surgeons mostly take the Fellowship by examination, though there are many hospital surgeons in London who have contented themselves with remaining Members.

A Member of the College of eight years' standing is admitted to examination on the production of a certificate of three Fellows, that he has been engaged for eight years in the practice of surgery, and is a fit and proper person to be admitted a Fellow.

THE MEMBERSHIP.

This diploma gives no vote in the affairs of the College. It is in effect only a licence to practise, and corresponds with the licentiateship of the Edinburgh and Dublin Colleges. Yet, during the past year, the Members, as well as the Fellows, were invited to a public meeting in the College.

In future, candidates for the diploma will be examined in the practice of medicine, and also in the practical employment of splints, bandages, and other surgical appliances.

APOTHECARIES' SOCIETY OF LONDON.

THE Licence of the Worshipful Society of Apothecaries is perhaps the most useful medical diploma for the general practitioner in England. The monoply enjoyed by this body for many years, in this respect, is not easily to be disturbed. The laws of many institutions require their medical officers to hold this diploma, and these laws are not readily altered. Though other medical qualifications are recognized by the Poor-law Board, there is no doubt that the guardians throughout the country—and they elect the medical officers—are familiar with the diploma of the Apothecaries' Society, and it is to them more of a guarantee than other qualifications, of the value of which they are ignorant. The drawback to many a student is that, constrained by the Act of Parliament, the Society requires apprenticeship. This clause has, however, received a very liberal interpretation, and every pupil of a licentiate, who is certified to have served *after the manner* of an apprentice, is considered to have fulfilled the requirement. During this term he may also have carried on his hospital studies. Everyone, therefore, who can show this certificate, intending to settle *in England* as a general practitioner—even if he take other diplomas—would probably consult his own interest by becoming a Licentiate of the Apothecaries' Society; and as the fee is only six guineas, a very large number of young men will, we doubt not, secure this possible avenue to appointments.

The next "Examination in Arts" will be held on Friday, the 23rd, and Saturday, the 24th inst., and the next "Registration" will be commenced on the 1st of October and ended on the 15th.

Having now considered the qualifying bodies of England, we pass on to the second consideration—the schools of medicine and hospitals—and first of all take those of the Metropolis.

Educational Institutions.

THE Schools of Medicine and the Hospitals to which they are attached next demand attention, inasmuch as at one of them the Student has to go through the curriculum prescribed by the licensing bodies.

In entering a School of Medicine, application is to be made to the Dean. In London the fees range from 80 to 120 guineas for the course of study required for the ordinary diplomas. The sum, if paid at once, is less than if paid in two or three instalments. From 40 to 45 guineas at the commencement of each of the two first years is an ordinary arrangement, the remainder being paid on entering the third winter. The amount of the fees does not differ so much as to make it of importance in the selection of a school.

We now proceed to name some of the characteristics of the most important London Schools.

THE LONDON HOSPITAL.

THIS large hospital is situated at the east end of London, in a district where accidents are of frequent occurrence, and as a field for the study of surgery has always been pre-eminent. It contains upwards of 500 beds; of these 160 are devoted to medical cases, and the remainder to surgery. About 200 are reserved for cases of accidents. The in-patients number about 5,000 a year; the out-patients 35,000. Special departments have been organised

for diseases of the eye, ear, and skin. Special wards are also set apart for venereal and obstetric cases. There are many prizes offered, and perhaps no school offers so many clinical appointments to the student without extra fees.

ST. BARTHOLOMEW'S HOSPITAL.

The great city hospital has always attracted large numbers of students from all parts of the country, so that the school is very flourishing.

H.R.H. the Prince of Wales is the President of the hospital, which receives within its walls upwards of 5,000 in-patients annually, and its out-patients and casualties amount to more than 100,000 annually. It contains 650 beds, of which 403 are allotted to surgical, including ophthalmic, orthopædic, aural, and syphilitic cases, and 247 to medical cases and diseases of women and children. One of the Assistant-Physicians sees the medical out-patients daily, between eleven and two ; and one of the Assistant-Surgeons sees the surgical patients daily, between twelve and two.

Accommodation is provided for residence of students in the college connected with the institution, for which an entrance fee of 2*l.* 2s., and a further payment of caution money, 3*l.* 3s., is required. The cost of maintenance varies from 30s. to 33s. per week, payable in each term ; and the term of residence is unlimited.

GUY'S HOSPITAL.

This old favourite borough school still attracts as many students as ever. The school is, we believe, one of the most popular in the metropolis, and from the excellence of its appointments, its situation, and superior staff, it still keeps up its old renown. In special departments, Guy's is the most advanced. This hospital has set the example of giving the appointments to its special departments to gentleman not on the staff. This liberality has enabled it to secure the leading specialists of the country in its service, and has done more than all the other hospitals together to put down all improper coquetting with specialism.

Guy's is situated close to the London Bridge Railways. Hence great facilities for getting to any part of London or the country. It is quite practicable for students to reside a little distance down either of the lines that converge at this point, and thus enjoy the benefit of country air during their hospital career. For those who wish to live close to the hospital, there are many lodgings to be had at a moderate price.

ST. THOMAS'S HOSPITAL.

This is the borough hospital which was removed for the Charing-cross Railway. The new hospital on the site at Stangate will soon be finished, when a new impetus must be given to the charity and the school.

There will be accommodation for residence and free maintenance in the College-house for the two house-surgeons, resident accoucheurs, one dresser, one obstetric clerk, and assistant obstetric clerk, which appointments are awarded by competition.

UNIVERSITY COLLEGE AND HOSPITAL.

This is situated in a very central position, near the Gower street Station of the Underground Railway, affording facilities for gentleman residing in many parts of London. The College gives instruction in every department of knowledge, and specially prepares students for degrees in all the Faculties at the University of London. There is, however, no theological faculty, the College, like the University with which it is in intimate connection, being founded on the non-sectarian principle. The Medical Faculty and the Hospital are very complete and flourishing as educational institutions. The University College School specially prepares boys to be ready at a proper age to enter the College.

KING'S COLLEGE.

This College gives instruction in all the faculties, and has a Theological Department. It was established by Church of England persons, in opposition to University College, which is a non-sectarian institution. King's, then, is the Church of England College. The College is situated close to Somerset House, having a frontage on the new Thames Embankment, within a few minutes' walk of a station on the Underground Railway. There is also a junior school in connection with this College, to prepare boys to enter the College at a proper age. The Hospital is only a short distance from the College, and although small, the renown of its staff has always kept up its reputation, so that King's is one of the most popular of the medical educational institutions in London.

CHARING CROSS HOSPITAL.

This hospital, though one of the smaller ones, derives from its situation great advantages. It is in one of the most central positions in London, where there is constant communication with every part. In connection with it the practice of the Royal Western Ophthalmic Hospital close by, affords an excellent opportunity for the study of that branch of the profession. Other special departments have been established, and the authorities seem to have the courage to establish them on a liberal basis, the hospital staff not monopolising these appointments.

ST. GEORGE'S HOSPITAL.

The chief advantage of this School is its unrivalled position, at the corner of Hyde Park—perhaps the most salubrious part of the metropolis. Students can easily find lodgings within half an hour's pleasant walk. It is, perhaps, the most aristocratic of the London schools, and the present staff maintain their position as worthy successors of Hunter, Brodie, and other worthies who formerly taught in it.

MIDDLESEX HOSPITAL.

The hospital contains upwards of 300 beds, of which 184 are for surgical, and 120 for medical cases. There is a special department for cancer cases affording accommodation for thirty-three in-patients, whose period of residence in the hospital is unlimited. Wards are also appropriated for the reception of cases of uterine disease and of syphilis, and beds are set apart for patients suffering from diseases of the eye.

Special attention is bestowed on the clinical instruction of the students both in the wards and out-patients' rooms. Three clinical prizes, including the governors', prize of twenty guineas, are annually awarded to those students who pass the most satisfactory examination at the bedside, and in the *post-mortem* room. Class prizes are also given, and six resident clinical appointments are annually awarded after competitive examination, to students who have completed their education and complied with the regulations of the school. The officers thus appointed reside and board in the hospital free of expense.

The college tutor assists all general students free of charge, especially those who are preparing for examination, and his daily instruction is arranged with a view to avoid the necessity of students obtaining any private teaching apart from that of the medical school.

WESTMINSTER HOSPITAL.

This is near the Abbey and the Houses of Parliament, and will be found convenient for all in that neighbourhood. It is well appointed in every respect, and one of the most moderate in respect to fees. The whole course of study for the usual examinations may here be completed for seventy-five guineas, payable in instalments. The perpetual fee is only eighty guineas. Resident appointments,

clerkships, and dresserships are all conferred without extra payments. Suitable lodgings may be obtained in the neighbourhood, and at not more than a quarter of an hours' walk from the hospital.

ST. MARY'S HOSPITAL.

THERE is a Medical School in connection with this hospital, which is located at Paddington, in close proximity to the Great Western Terminus. Students with slender purses will find the neighbourhood of the hospital a very moderate one as regards lodgings, and easy of access by omnibus and the Underground Railway to all parts of London. The Clinical Department is very complete. Wards are devoted to the Diseases of Women, including Ovariotomy, and to Ophthalmic Cases. Special study is also provided for in the Out-patient Department for Diseases of the eye, the ear, the skin, and the throat. Three resident medical officers are appointed for twelve months, and an obstetric officer for six months, who board free of expense in the hospital. A resident registrar is also appointed from amongst the students, with a salary of 100*l.* a-year. These appointments are awarded after competition, without additional fee.

Instructions to Students about to enter the Medical Profession.

1.

IN order to be registered as a Medical Student it is absolutely necessary to pass a *Preliminary Examination in Arts.*

The following are the Examinations, Certificates of which are at present recognised by the General Medical Council.

a. A *Degree in Arts* of any University of the United Kingdom, or of the Colonies, or of such other universities as may be specially recognised from time to time by the Medical Council.

b. A Certificate of either of the following :—

Preliminary Examination in Arts of Royal College of Physicians, Edinburgh ; Royal College of Surgeons, Edinburgh ; Royal College of Surgeons, Ireland ; Faculty of Physicians and Surgeons of Glasgow ; Apothecaries' Hall, Ireland.

Oxford—Responsions or Moderations.

Cambridge—Previous Examinations.

Durham—Examinations for Students in their Second and and First years.

Durham—Registration Examination for Medical Students.

Oxford, Cambridge, Durham—Local Examinations (Senior), Certificate to include Latin and Mathematics.

Aberdeen, Edinburgh, Glasgow, St. Andrew's—Preliminary Examination for Graduation in Medicine or Surgery.

Edinburgh—Examination of (Senior) Candidates for Honorary Certificates under the local Examinations of the University of Edinburgh.

Dublin—University Entrance Examination.

Queen's University, Ireland—Entrance Examination ; Examination for the Diploma of Licentiate in Arts ; Previous Examination for B.A. Degree.

First Class Certificate of the College of Preceptors.

University of Calcutta, Madras, Bombay—Entrance Examination ; Certificate to include Latin.

M'Gill College, Montreal—Matriculation Examination.

University of Toronto ; King's College, Toronto ; Queen's College, Kingston ; Victoria College, Upper Canada—Matriculation Examination.

University of King's College, Nova Scotia—Matriculation Examination or Responsions.

University of Fredericton, New Brunswick—Matriculation Examination.

University of Melbourne—Matriculation Examination, Certificate to include all the subjects required by the General Medical Council.

University of Sydney—Matriculation Examination.

Codrington College, Barbadoes—1. English Certificate for Students of two years' standing, specifying the subjects of Examination. 2. Latin Certificate, or 'Testamur.'

Tasmanian Council of Education—Examination for the Degree of Associate of Arts, Certificate to include Latin and Mathematics.

Christ's College, Canterbury, New Zealand—Voluntary Examination, Certificate to include all the subjects required by the General Medical Council.

2.

Supposing a Student not to possess a Certificate of any one of the preceding, it will be necessary for him to pass one or other of the following Preliminary Examinations before he can be registered as a Medical Student or enter a Medical School. (A.) The Royal College of Surgeons. (B.) The Apothecaries' Hall. (C.) The University of London. The last is by far the best, as it gives a certain status.

3.

REGISTRATION OF MEDICAL STUDENTS.

Every Medical Student must be registered in the manner prescribed by the General Medical Council, within fifteen days of commencing study.

Every person desirous of being Registered as a Medical Student must apply to the Branch Registrar of the division of the United Kingdom in which he is residing ; and produce or forward to the Branch Registrar a Certificate of his having passed a Preliminary Examination, as required by the General Medical Council, and a statement of his place of Medical study.

The several Qualifying Bodies are required not to admit after October, 1870, to the final Examination for a Qualification under the Medical Acts, any Candidate (not exempted from Registration) whose names had not been entered in the Medical Students' Register at least four years previously.

In the case of Candidates from other than Schools of the United Kingdom, the Branch Councils have power to admit exceptions to this Recommendation.

SPECIAL DETAILS AS TO REGULATION OF QUALIFYING BODIES THAT DO NOT REQUIRE RESIDENCE.

REQUIREMENTS OF QUALIFYING BODIES.

UNIVERSITY OF LONDON.

Degrees in Medicine and Surgery are granted by the University. Students are required to pass—1st, the Matriculation Examination (General Education) ; 2nd, the Preliminary Scientific (including Inorganic Chemistry, Mechanical and Natural Philosophy, Botany and Zoology). The Senate of the University recommend Students to pass this Examination before commencing their Medical studies ; 3rd, the first M.B. Examination (including Anatomy, Physiology, Materia Medica, and Organic Chemistry) ; 4th, the second M.B. Examination (including Medicine, Surgery, Midwifery, Forensic Medicine, Pathology, Hygiene and Therapeutics, and Hospital Medical and Surgical Practice). The total fees for the M.B. degree are 17*l.*, for the M.S. degree 5*l.* additional.

ROYAL COLLEGE OF PHYSICIANS OF ENGLAND.

Attendance on the following course of Lectures is required for the license of this body, *i.e.*, Anatomy (with Dissections) and Physiology, during two winter session ; Chemistry, six months ; Practical Chemistry, Materia Medica, Practical Pharmacy, and Botany, three months each ; Morbid Anatomy, six months ; Principles and Practice of Medicine, during two winter sessions ; Clinical Medicine during three winter and three summer sessions ; Principles and Practice of Surgery, during two winter sessions ; Clinical Surgery, during two winter and two summer sessions ; Midwifery and the Diseases peculiar to Women, and Forensic Medicine, three months each ; Hospital practice—*Medical*, three winter and three summer sessions ; *Surgical*, three winter and two summer sessions ; Diseases of Women, six months ; Clinical Medical Clerk, at least six months. The fee for the license is fifteen guineas. The examination is divided into two parts, from the first of which a candidate is exempted, provided he has passed the first or Anatomical Examination of any other Examining Board.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The following courses of Lectures and Hospital Practice are required for the diploma of this body; Practical Pharmacy, three months; Descriptive and Surgical Anatomy, Dissections, Physiology, Surgery, two courses each of six months' duration; Medicine and Chemistry, one course each of six months; Materia Medica, Midwifery, with practical instruction, one course each, of three months; Instruction and Proficiency in Vaccination. Hospital practice—*Surgical*, with Clinical Lectures, three winter and two summer sessions; *Medical*, with Clinical Lectures, one winter and one summer session; Dressership, or charge of patients, six months after the completion of the second year of professional study. The fee for the diploma is 22*l*. There are two examinations, the first at the end of the second winter in Anatomy and Physiology, the second at the end of the fourth year in Surgery, Surgical Pathology, Medicine and Midwifery also.

WORSHIPFUL SOCIETY OF APOTHECARIES OF LONDON.

The following courses are required for the license: Descriptive and Surgical Anatomy, Physiology and Dissections, Medicine, two courses, of six months each; Chemistry and Morbid Anatomy, one course, of six months each; Practical Chemistry, Materia Medica, Midwifery, Forensic Medicine, and Toxicology, and Botany, one course, of three months each. Hospital Medical Practice and Clinical Lectures, two winter and two summer sessions. An apprenticeship of five years. The fee for the license is 6*l*. 6s. The examination is divided into two parts.

THE SCOTTISH DOUBLE QUALIFICATION.

Candidates for the licences of these bodies are required to attend the following courses of Lectures: Anatomy, Practical Anatomy, Physiology, Medicine, and Surgery, two courses of six months each; Materia Medica, Practical Chemistry, Forensic Medicine, Midwifery, and Diseases of Women and Children, Pathological Anatomy, Practical Pharmacy, one course of three months each. Hospital practice—Medical and Surgical, with Clinical Lectures, two winter and two summer sessions each; Certificate of Proficiency in Vaccination. The fee for the Double Qualification is 16*l*. There are two Examinations.

VACATIONS.

There are Three Months' Vacations during the year—viz., APRIL, after the Winter Session, and AUGUST and SEPTEMBER, after the Summer Session.

ORDER OF STUDY.

The following Order of Study meets the regulations of all the above Examining Boards:—

FIRST WINTER SESSION.—Chemistry, Anatomy, Physiology, Dissections, Surgical Hospital Practice, Surgical Clinical Lectures.

FIRST SUMMER SESSION.—Materia Medica and Therapeutics, Botany, Practical Chemistry, Practical Pharmacy, Surgical Hospital Practice, Surgical Clinical Lectures.

SECOND WINTER SESSION.—Anatomy, Physiology, Dissections, Principles and Practice of Medicine, Principles and Practice of Surgery, Medical Hospital Practice, Surgical Hospital Practice, Surgical Clinical Lectures.

SECOND SUMMER SESSION.—Midwifery, Medical Jurisprudence, Medical Hospital Practice, Medical Clinical Lectures, Surgical Hospital Practice, Surgical Clinical Lectures, Demonstrations of Morbid Anatomy.

THIRD WINTER SESSION.—Principles and Practice of Medicine, Principles and Practice of Surgery, Medical Hospital Practice, Medical Clinical Lectures, Surgical Hospital Practice, Surgical Clinical Lectures, Demonstrations of Morbid Anatomy, Practical Midwifery.

THIRD SUMMER SESSION.—Medical Hospital Practice, Medical Clinical Lectures, Demonstrations of Morbid Anatomy, Practical Midwifery.

FEES PAYABLE FOR ALL LECTURES AND HOSPITAL PRACTICE REQUIRED FOR THE ABOVE DIPLOMAS.

LONDON.	£	s.	d.

Special Details respecting Educational Institutions.

QUEEN'S COLLEGE, BIRMINGHAM.

Professors of the Medical Faculty.—Winter Courses: Medicine, Dr. James Russell, Dr. Balthazar W. Foster; Surgery, Mr. Oliver Pemberton, Mr. Furneaux Jordan; Anatomy, Mr. Charles J. Bracey, M.B. Lond., and J. F. West, F.R.C.S.; Physiology, Dr. Richard Norris, Mr. T. H. Bartleet, M.B. Lond.; Chemistry, Dr. Alfred Hill, F.C.S.; Demonstrator of Anatomy, Mr. William Thomas, M.B. Lond., F.R.C.S. Summer Courses: Midwifery, Mr. John Clay, Mr. John Bassett; Diseases of Women and Children, Mr. Samuel Berry and Dr. R. C. R. Jordan; Forensic Medicine and Toxicology, Mr. Thomas Swain and Dr. Alfred Hill; Practical Chemistry, Mr. Alfred Anderson, F.C.S.; Botany, Dr. Wiliam Hinds; Materia Medica and Therapeutics, Mr. J. St. S. Wilders and Mr. Edward Mackey, M.B. Lond.; Ophthalmic Surgery, Mr. J. Vose Solomon; Dental Surgery, Mr. Thos. Hawkins; Comparative Anatomy, Dr. Thomas Savage; Medical Tutor and Registrar, Mr. James Hinds, M.B. Lond.

Hospital Practice may be attended at either the General Hospital or the Queen's Hospital, which are equidistant from the College.

Resident Students.—Students may reside within the College, where they will be provided with rooms and board, and will be under the supervision of the Warden and Resident Tutors, Resident Students are expected to attend the College Chapel, unless specially exempted by the Warden.

Resident Tutors.—The Professor of Classics, the Profesor of Mathematics, and the Medical Tutor.

Scholarships and Prizes.—Two Warneford Scholarships, the Sands Cox Prize (value of 20*l*.), the Warden's Prize (of the value of five guineas), the Percy Prize (books of the value of five guineas), and Class Prizes, Medals, and Certificates of Honour are awarded annually.

The prospectus of the Medical Department, and further information, may be obtained by application to the Rev. the Warden at the College; or to Professor Foster, M.D., 4 Old square, Birmingham, Physician to the General Hospital; or to Professor Furneaux Jordan, Colmore row, Birmingham, Surgeon to the Queen's Hospital.

THE QUEEN'S HOSPITAL, BIRMINGHAM.

Physicians, Dr. Fleming, Dr. Johnston, Dr. Heslop. Surgeons, Mr. West, Mr. Gamgee, Mr. Furneaux Jordan, Mr. J. St. S. Wilders. Dental Surgeon, Mr Adams Parker. Resident Physician and Medical Tutor, Dr. Sawyer. Resident Surgeon and Surgical tutor, Dr. Jolly.

Several Clinical Prizes are offered for competition to Students of the second, third, and fourth years. They vary from 2*l.* 2s. to 5*l.* 5s. in value.

The Hospital has special wards for Diseases of Children and Venereal Diseases. Clinical Lectures and Instruction are delivered daily at the Hospital by the Physicians and Surgeons. Fees are to be paid to Mr. H. C. Burdett, Resident Secretary to the Hospital. The register of tickets for attendance on Clinical Lectures, and on Medical and Surgical Practice, is open at the Hospital from October 1 to October 15, 1870, and May 1 to May 15, 1871. Special instruction in Dental Surgery by Mr. Adams Parker. Fee, 2*l.* 2s.

GENERAL HOSPITAL, BIRMINGHAM.

Physicians, Dr. Bell Fletcher, Dr. Russell, Dr. Wade, Dr. Foster. Surgeons, Mr. Alfred Baker, Mr. Oliver Pemberton, Mr. T. H. Bartleet, Mr. W. P. Goodhall. Resident Physician and Tutor, Dr. Welch. Resident Surgeon, Mr. May.

Clinical Lectures are delivered by the Physicians and Surgeons every week during the Session.

BRISTOL MEDICAL SCHOOL, SESSION 1870-71.

The Winter Session will commence on Monday, October 3, 1870. Medicine, Dr. Martyn and Dr. Fox, Surgery, Mr. Coe and Mr. Leonard. General Anatomy and Physiology, Messrs. Atchley and Steele. Descriptive and Surgical Anatomy, Mr. Lansdown and Mr. Tibbits. Superintendence of Dissections, Messrs. Dowson and Dobson. Chemistry, Mr. Coomber.

The Summer Session will commence on May 1, 1871. Midwifery, and Diseases of Women, Dr. J. G. Swayne. Forensic Medicine, Mr. E. C. Board. Materia Medica and Therapeutics, Dr. G. F. Burder. Botany, Mr. A. Leipner. Practical Chemistry, Mr. Coomber. Comparative Anatomy, Mr. Atchley.

Competitive Examinations are held amongst Students of the first, second, and third years respectively; and prizes of money, instruments, and books, are annually awarded.

Medical and Surgical Hospital Practice and Clinical Lectures are attended at the Royal Infirmary or at the General Hospital.

BRISTOL ROYAL INFIRMARY.

The Infirmary contains 242 beds. Physicians, Dr. Brittan, Dr. Fairbrother, Dr. Fox, Dr. Beddoe. Surgeons, Mr. Bernard, Mr. Leonard, Mr. Clark, Mr. Tibbits, and Mr. Steele.

Clinical Clerks are appointed without extra fee. A Gold Medal and other Prizes are awarded annually. Patients admitted in 1869; In-patients, 2,655; out-patients, 21,933; total, 24,588.

BRISTOL GENERAL HOSPITAL.

The Hospital contains 130 beds. Physicians, Dr. Martyn, Dr. Burder, Dr. Fripp. Surgeons, Mr. Coe, Mr. Lansdown, Dr. H. Marshall, Mr. G. F. Atchley. Physician-accoucheur, Dr. Swayne. Two Scholarships of 15*l.* each are awarded annually. Also a Scholarship, called the Sanders Scholarship for the study of Medicine and Surgery, being the interest of 500*l.* (to be given annually), bequeathed to the Hospital by the late J. N. Sanders, Esq.

Resident Pupils (including board, lodging, and washing), 100*l.* for the first year, 60*l.* for each subsequent year. Or for five years, with apprenticeship to the Hospital, 260*l.*

LEEDS SCHOOL OF MEDICINE.

The Winter Session will commence on Monday, October 3, 1870. Anatomy, by James Seaton, M.R.C.S., Robert T. Land, M.D., M.R.C.S., and John A. Nunneley, M.B., M.R.C.S. Physiology, by William Hall, M.R.C.S., and Thomas R. Jessop, F.R.C.S. Principles and Practice of Medicine, by Charles Chadwick, M.D., F.R.C.P., John D. Heaton, M.D., F.R.C.P., and T. C. Allbutt, M.A., M.D., F.L.S. Principles and Practice of Surgery, by Claudius G. Wheelhouse, F.R.C.S., and T. Pridgin Teale, M.A., F.R.C.S. Chemistry, by J. Chapman Wilson, F.C.S. Materia Medica, by John E. Eddison, M.D. Midwifery, by W. Hall, M.R.C.S. Forsenic Medicine, by Thomas Scattergood, M.R.C.S. Botany, by Edward Atkinson, M.R.C.S., F.L.S. Comparative Anatomy, by C. G. Wheelhouse, F.R.C.S., and T. C. Allbutt, M.A., M.D., F.L.S. Assistant-Demonstrators of Anatomy, Robert Parr Oglesby, M.R.C.S., and Charles James Wright, M.R.C.S. Demonstrations in Operative Surgery, by Messrs. S. Hey, C. G. Wheelhouse, and Pridgin Teale. Demonstrations of Skin Diseases, by Dr. Allbutt, at the Infirmary. Ophthalmoscopic Demonstrations, by Mr. T. Prigdin Teale.

Prizes.—At the close of each Session, Examinations for Prizes are held, when Silver and Bronze Medals, Books, and Certificates of Honour are presented according to merit. Two Clinical Prizes of 10*l.* each, a Forsenic Medicine prize of 10*l.*, and two Chemical Scholarships, are awarded to Students.

Clinical Clerkships and Dresserships.—In accordance with the recent requirements of the Examining Boards, it is now arranged that every Student in turn shall pass through the offices of Clinical Clerk and Dresser. No Certificate of Hospital Practice will be granted to Students who have not held these offices.

Resident Medical Officers.—Four House-Surgeons are elected for the service of the Infirmary, to work under the direction of the Resident Medical Officer. They are chosen from those senior Students who have shown industry and skill as Dressers and Clinical Clerks. They are provided with private apartments, board, gas, and coal, in the Hospital, without charge.

Honorary Medical Officers of the Hospital.—Consulting Surgeon: William Hey, F.R.C.S. Physicians: Charles Chadwick, M.D., F.R.C.P.; John Deakin Heaton, M.D., F.R.C.P.; and T. Clifford Allbutt, M.A., M.D., F.L.S. Surgeons: Samuel Hey, F.R.C.S.; C. G. Wheelhouse, F.R.C.S.; T. Pridgin Teale, M.A., F.R.C.S.; T. R. Jessop, F.R.C.S.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE.

The Introductory Address will be delivered on October 3, 1870, at 3 p.m., by Dr. Brown.

Hospital Practice, Royal Infirmary.—Physicians, Dr. Vose, Dr. Turnbull, Dr. Inman. Surgeons, Mr. Stubbs, Mr. Bickersteth, Mr. Hakes. Assistant-Surgeons, Mr. Harrison. House-Surgeons, Dr. Cleaver and Mr. Matthews. Pathologist, Mr. Banks. Dental Surgeon, Mr. Snape.

Lectures, Winter Session.—Medicine, Dr. Cameron. Surgery, Mr. Harrison. Physiology, Dr. Waters. Anatomy, Mr. W. M. Banks. Dissection, Dr. Glynn and Mr. E. A. Browne. Chemistry, Dr. Brown.

Lectures, Summer Session.—Midwifery, Dr. Steele. Diseases of Children, Dr. Gee. Materia Medica, Dr. Nevins. Medical Jurisprudence, Dr. E. Whittle, Toxicology and Practical Chemistry, Dr. Brown. Botany, Dr. W. Carter. Ophthalmic Medicine and Surgery, Dr. Hibbert Taylor. Comparative Anatomy and Zoology, Dr. Davidson.

Exhibitions.—Royal Infirmary Medical Scholarship—value 42*l.*—consisting of Gold Medal, value 10*l.* 10s., and Six Months' Free Board and Residence, with Clerkship and Dressership, in the Royal Infirmary.—Four Exhibitions—value 31*l.* 10s. each—consisting of Six Months' Free Board and Residence in the Royal Infirmary.

NEWCASTLE-ON-TYNE SCHOOL OF MEDICINE.

Hospital Practice is obtained at the Newcastle Infirmary, which contains 230 beds, and in which the required Clinical Lectures are delivered. Two Resident Clinical Clerkships, four Resident Dresserships, and four Non-resident Dresserships, are gratuitous, at the disposal of the Physicians and Surgeons. There are four Scholarships of 25*l.* a-year, each tenable for four years by Students residing at Durham, or Newcastle, also the Dickinson Scholarship of 15*l.* for general proficiency. At the end of each Session a Silver Medal and Certificate of Honour will be awarded, after examination, to the best Student in each class.

SHEFFIELD SCHOOL OF MEDICINE.

THE practice at this school affords an excellent field for study, especially Operative Surgery, in consequence of the large number of Accidents continually occuring in the manufacturing Establishments surrounding. The Sheffield Royal Infirmary contains 150 beds, and is an admirably appointed institution.

MANCHESTER ROYAL SCHOOL OF MEDICINE AND SURGERY, FAULKNER STREET.

The Winter Session will commence October 3, with an Introductory Address by L. H. Grindon.

Winter Session, 1870-71.—Physiology, by Mr. Smith. Descriptive Anatomy, by Mr. Lund and Mr. Bradley. Practical Anatomy, by Mr. S. M. Bradley. Chemistry, by Mr. Stone. Principles and Practice of Medicine, by Dr. Roberts and Dr. Morgan. Principles, Practice, and Operations of Surgery, by Mr. Southam. Anatomy, Physiology, and Pathology, of the Eye, by Mr. Hunt.

Summer Session.—Midwifery and Diseases of Women and Children, Dr. Thorburn. General Pathology and Morbid Anatomy, by Dr. Simpson. Materia Medica, Medical Botany, and Therapeutics, by Mr. Somers. Forensic Medicine, by Mr. Harrison. Botany, by Mr. Grindon. Practical Chemistry, by Mr. Stone. Comparative Anatomy, by Mr. Bradley.

Scholarships.—In addition to prizes, amounting to 36 guineas, for general proficiency, Three Scholarships for perpetual students will be offered for competition—one of 20*l.* for third year's students; one of 15*l.* for second year's students; one of 10*l.* for first year's students.

ROYAL INFIRMARY, EDINBURGH.

In this Hospital a portion of the beds is set apart for Clinical Instruction by the Professors of the University of Edinburgh. Courses of Clinical Medicine and Surgery are also given by the Ordinary Physicians and Surgeons. Separate Wards are devoted to Fever, Small-pox, Venereal Diseases, Diseases of Women, Diseases of the Eye; also to cases of Incidental Delirium or Insanity. Post-mortem Examinations are conducted in the Anatomical Theatre by the Pathologist, who also gives Practical Instruction in Pathological Anatomy and Histology. Professors of Clinical Medicine, Dr. Bennett, Dr. Laycock, Dr. Maclagan, Dr. Sanders. Extra Physician and Lecturer on Diseases Peculiar to Women, Dr. J. Matthews Duncan. Ordinary Physicians and Lecturers on Clinical Medicines, Dr. Rutherford Haldane, Dr. Geo. W. Balfour, Dr. T. Grainger Stewart. Assistant-Physicians, Dr. Claud Muirhead, Dr. Thos. R. Fraser. Consulting-Surgeon, Dr. Dunsmure. Professor of Surgery, Mr. Spence. Ordinary Acting-Surgeons, Dr. J. D. Gillespie (Lecturer on Clinical Surgery), Dr. P. H. Watson, Mr. Thos. Annandale. Professor of Clinical Surgery, Mr. Lister. Ophthalmic Surgeons, Mr. Walker, Dr. D. A. Robertson. Assistant-Surgeons, Dr. Joseph Bell, Dr. John Duncan. Dental Surgeon, Dr. John Smith. Pathologist, Dr. James B. Pettigrew. Hospital Tickets.—Perpetual, in One Payment, 10*l.*; Annual, 5*l.* 5*s.*; Half-yearly, 3*l.* 3*s.*; Quarterly, 1*l.* 11*s.* 6*d.* Separate payments for Two Years entitle the Student to a Perpetual Ticket. No Fees are payable for any Medical or Surgical Appointment in this Hospital.

UNIVERSITY OF ABERDEEN.

Faculty of Medicine—Session 1870-71.

Winter Session commencing on Wednesday, October 26.—Anatomy, Professor Struthers, M.D., 3*l.* 3*s.* Practical Anatomy and Demonstrations, Professor Struthers and the Demonstrator, 2*l.* 2*s.* Chemistry, Professor Brazier, 3*l.* 3*s.* Institutes of Medicine, Professor Ogilvie, 3*l.* 3*s.* Surgery, Professor Pirrie, 3*l.* 3*s.* Practice of Medicine, Professor Macrobin, M.D., 3*l.* 3*s.* Midwifery and Diseases of Women and Children, Professor Inglis, 3*l.* 3*s.* Zoology, with Comparative Anatomy, Professor Nicol, 3*l.* 3*s.* Medical Jurisprudence, Professor Ogston, 3*l.* 3*s.*

Summer Session, commencing on the first Monday in May.—Botany, Professor Dickie, 3*l.* 3*s.* Materia Medica (100 Lectures), Professor Harvey, 3*l.* 3*s.* Practical Anatomy and Histology, Professor Struthers and the Demonstrator, 2*l.* 2*s.* Practical Chemistry, Professor Brazier, 3*l.* 3*s.* Zoology, with Comparative Anatomy, Professor Nichol, 3*l.* 3*s.*

Matriculation Fee for the Winter and Summer Sessions, 1*l.* For the Summer Session alone 10*s.*

Royal Infirmary: Perpetual Fee to Hospital Practice, 6*l.*; or First Year, 3*l.* 10*s.*; Second Year, 3*l.* Clinical Medicine, Drs. Harvey and Smith, 3*l.* 3*s.* Clinical Surgery, Drs. Pirrie, Kerr, and Fiddes, 3*l.* 3*s.* Pathology, Dr. Rodger, 2*l.* 2*s.* Dental Surgery, Mr. Williamson.

UNIVERSITY OF GLASGOW.

Faculty of Medicine.—The Classes open for the Winter Session on Tuesday, October 25, 1870, when an Introductory Lecture will be given by Professor Young.

Chemistry, Practical Chemistry, and Chemical Laboratory, Dr. Anderson, 3*l.* 3*s.* Practice of Physic, Dr. Gairdner, 3*l.* 3*s.* Anatomy, Anatomical Demonstrations, and Practical Anatomy, Dr. Allen Thomson and Demonstrator, 8*l.* 8*s.* Materia Medica, Dr. Cowan, 3*l.* 3*s.* Forensic Medicine, Dr. Rainy, 3*l.* 3*s.* Surgery, Dr. Macleod, 3*l.* 3*s.* Midwifery, Dr. Leishman, 3*l.* 3*s.* Institutes of Medicine, Dr. A. Buchanan, 3*l.* 3*s.* Clinical Medicine and Clinical Surgery, Physicians and Surgeons of Royal Infirmary.

ANDERSON'S UNIVERSITY, GLASGOW.

WINTER SESSION 1870 OPENS OCTOBER 26.

Chemistry, Practical Chemistry, and Laboratory, Vacant; Surgery, Dr. James Dunlop; Institutes of Medicine (Physiology), Dr. Watson; Anatomy, Anatomical Demonstrations, Practical Anatomy, or Dissection, Dr. G. Buchanan; Practice of Medicine, Dr. M'Call Anderson; Materia Medica, Dr. Morton; Hospital Practice in Royal Infirmary; Clinical Lectures in Royal Infirmary.

SUMMER SESSION.

Midwifery, Dr. J. G. Wilson; Medical Jurisprudence, Dr. P. A. Simpson; Surgical Anatomy, Practical Anatomy, Osteology for beginners, Dr. George Buchanan; Practical Chemistry, Vacant.

Class Fees: For each of the above Courses of Lectures, first Session, 2*l.* 2*s.*; second Session, 1*l.* 1*s.*; afterwards free.

Anatomy Class Fees: For both Courses (Lectures and Demonstrations), first Session, 4*l.* 4*s.*; second Session, 4*l.* 4*s.*: afterwards free.

Practical Anatomy; The Dissecting-room is free for two Sessions to those who attend both Courses of Anatomy. After the second year the fee for Practical Anatomy is 1*l.* 1*s.* per Session.

The Fees for all the Lectures and Hospital Practice required of Candidates for the Diplomas of Physicians and Surgeon amount to 45*l.*

GLASGOW ROYAL INFIRMARY.

The Winter Session commences on November 1, 1870. Physicians, Drs. W. T. Gairdner, Steven Perry, M'Call Anderson, and Scott Orr. Surgeons, Drs. E. Watson, Dewat, Macleod, G. Buchanan, and J. Morton. Fever Physicians, Drs. James Maclaren and M. Charteris.

Number of beds, 583.

Besides the Clinical Instruction given at the bedside, Lectures on the Cases are given four times weekly, at 9 a.m., during the Winter and Summer Sessions. Regular Operating days—Wednesdays and Saturdays.

The valuable Pathological Museum is open to all Students who desire to examine the Preparations.

Five Physicians' and Five Surgeons' Assistants perform the duties of House-Physicians and House-Surgeons. These offices, held for one year, are open to Students of the fourth year. They are lodged and boarded in the Hospital for 25*l.* per annum. Dressers to the Surgical Wards and Clerks to the Dispensary are appointed without fee.

Fees admitting to the Medical and Surgical Practice and the Clinical Lectures:—For Ticket: the first year, 3*l.* 3*s.*; second year, 3*l.* 3*s.*; third and perpetual, 1*l.* 1*s.*; for six months' attendance, 2*l.* 2*s.*; three months', 1*l.* 11*s.* 6*d.* Practical Pharmacy, six months, 3*l.* 3*s.*

Fees for Clinical Lectures, on Medicine, 3*l.* 3*s.*, on Surgery, 3*l.* 3*s.*

IRELAND.

THE practice of the Profession in Ireland, though not nearly as remunerative as in England, still affords a certain prospect to any Medical man who is content with modest independence. Irish Medical men pride themselves on holding a higher social position than the English general Medical practitioner. They are entitled to meet the gentry of their locality on terms of equality, and it is not necessary or usual for them to endanger their prestige by the adoption of the trading or Christmas bill system which obtains elsewhere. In fact, what they lose in income they gain in rank.

In order to put the career of the Irish Student as plainly as possible, we narrate the progress of an ideal person, from the day on which he takes his first step towards medicine to the hour of his issue from the *cocoon* of studentship, a fully-developed surgeon.

The parents and guardians of Master Robert Sawyer have, after much discussion, decided that he shall be a doctor. He has had a moderate amount of schooling, at least the very moderate amount which is essential for the Medical preliminary examinations, and his father is ready to expend at least £130 on his Medical education, that sum being divided over four years, or paid down in order to secure the advantage of a considerable saving.

THE CHOICE OF SCHOOLS AND COLLEGES

will depend on various circumstances, and on the aspirations of Master Sawyer. If he's intended to make a fortune and enlighten his generation as a metropolitan practitioner, and if money and education are plenty, he will probably take University degrees in Arts and in his profession. If the attainment of fair professional rank on moderate terms be desired, the College of Surgeons and College of Physicians will serve every purpose. If cheapness and the obtaining a licence to practise without much trouble or severe study be the object, there are Licensing Bodies who will be glad to meet the views of the candidate.

The choice of a School, Hospital, and College having been made, Master—now *Mister*—Sawyer is perhaps sent to those to pass his

PRELIMINARY EXAMINATION

in general education, but if he be either lazy or ignorant, he may adjourn that unpleasant process, *de die in diem*, until the eve of his final qualification as a Surgeon. The preliminary examination is, however, not to be feared, inasmuch as most Licensing Bodies are anxious to secure students by making the first steps in learning very easy.

The preliminary examination (of the subjects of which details will be found in the official regulations of each College) having been passed or postponed, Mr. Sawyer comes to town to begin work.

He may do so either (1.) on his own account, or (2.) he may become voluntarily a pupil of some Medical man, usually a teacher or hospital surgeon, who can assist him in his studential course. This is by no means a requirement of any of the Colleges; it is purely a matter of option. Should the student pursue the first course, he usually comes to town, takes a lodging close to his School and Hospital, either by himself or in companionship with some *chum*, and either arranges to maintain himself or to board with his landlady. There is, of course, every degree of expense and of comfort, but we should say that reasonable yet frugal living may be had in Dublin at about 10s. per week for lodging, and £5 to £6 per month for maintenance.

We would here, as a matter of private judgment, remark that it is better for parents to have board provided on a good substantial scale by the house. Young men are too apt to spend their money on luxuries or extravagancies, and make up the deficit by using insufficient food, to the great injury of the health.

APPRENTICESHIP.

Should the student prefer becoming a pupil of some Medical man, hospital surgeon or lecturer, he can make terms by private agreement, either as a resident in the house of his master or as an extern pupil. The terms for such advantages vary considerably. A usual bargain is that the master shall, in consideration of a payment varying from £125 to £150, undertake to pay all educational expenses whatsoever, and, in addition, the intern pupil pays £6 6s. per month for his maintenance during the nine months he is in town. Under other arrangements the master will receive, say £100, for a session of nine months, and will undertake all expenses, whether professional or domestic.

These sums are what we would consider fair to both sides; but as it is a matter of voluntary arrangement and of superiority of advantages, experience, and success offered, we can only suggest what seems equitable.

COST OF EDUCATION.

Should the student proceed on his account, the lectures necessary for the L.R.C.S.I. will amount to £65; hospital attendance about £25; lying-in hospital from £4 4s. to £7 7s. These, with the diploma fee of £26 5s., represent the essentials. The sum of £52 10s., paid down at the commencement, is taken by the College of Surgeons as payment in full for all lectures requisite, and all the hospitals allow a considerable discount. Thus, the absolute payment will amount to somewhere about £83, taking the minimum mode of payment. In addition to this sum are to be considered the payments for "grinding" or "coaching," as the Londoners call it, the fixed sum is, for private teaching, £15 15s. for the surgical and medical qualifications, and £5 5s. for pharmacy, &c. Should the candidate "grind" for the army and navy examinations, a fee varying from £10 10s. to £21 is, we believe, usual. Should the candidate perform operations on the subject as a practice, they will cost something extra. So that, assuming the extras or voluntary costs are incurred, the total will vary say from £114 to £120 on a moderate scale; it is of course to be expected that pupil holders should have some extra payment, we, therefore, have named £155.

If Mr. Sawyer becomes an apprentice, he need trouble himself nothing about his payments. If he is his own manager, he must enter his name with the Secretaries of the School and Hospital, and pay for the Lectures and Hospital he intends to take out. If he is wise he will not adjourn the majority of his lectures, as he may, to the next year, but will take in his first year a full third of his curriculum. He is supposed to pay the Professor's fee or Hospital fee in full on entering his name, but few students do so, and many, we are sorry to say, are in the habit of entering for the minimum allowable number of lectures, and paying the minimum allowable proportion of the fee, putting off the attendance perhaps for ever, certainly until the last moment, and adjourning the payment until they must take up the certificates.

The entry of names and commencement of study is supposed to date from the 1st of October in each year, but really does date from the 1st of November, and may be delayed by the dilatory until the 25th of the same month.

Mr. Sawyer then begins work, attending Hospital each morning at nine o'clock, and occupying his day from half-past eleven to five between lectures and dissections. His holidays —if the term be not ignoble—are a fortnight at Christmas and a week at Easter, and he finally returns home at the end of July.

The progress of each year is the same, except that he usually devotes more attention to "grinding," dissection, and hospital dresserships, and less to lectures in his latter years of study, and after the expiration of his third session, his student-life, whether it begin in laziness and end in hurry and incompetency, or whether it commence in diligence and end in the

confidence of proficiency, ends with his last examination, and he goes forth into the world either an ignoramus or a reliable surgeon, whichever his choice may have been.

Regulations and Bye-Laws of Licensing Bodies in Ireland.

UNIVERSITY OF DUBLIN.

THE following Degrees and Licences in Medicine and Surgery are granted by the University of Dublin :—

1. Bachelor in Medicine. 2. Doctor in Medicine. 3, Master in Surgery. 4. Licentiate in Medicine. 5. Licentiate in Surgery.

Matriculation.

Every student must be matriculated by the senior lecturer, for which a fee of five shillings is payable ; but he need not have his name on the College books, or attend any of the academical duties, unless he desire to obtain a Licence or Degree in Medicine or Surgery. No student can be admitted for the Winter Courses after the 25th of November.

QUALIFICATIONS FOR DEGREES AND LICENCES.

Bachelor in Medicine.

Candidates must be graduates in Arts, and may obtain the degrees at the same commencements as the B.A., or at any subsequent one. The medical education of a Bachelor in Medicine is of four years' duration, and comprises the following lectures :—

Winter Courses.—Anatomy and Physiology—Practical Anatomy with Dissections—Surgery—Chemistry—Practice of Medicine—Midwifery.

Summer Courses.—Botany—Materia Medica and Pharmacy—Institutes of Medicine—Medical Jurisprudence.

Hospital attendance on Sir Patrick Dun's during nine months, with three consecutive courses of clinical lectures. Also nine months' additional attendance on a recognised hospital, and Practical Midwifery.

Any of the courses may be attended at any recognized medical school, and three of them at Edinburgh University, provided the candidates have kept an Annus Medicus in the School of Physic.

The schools recognised are—1. The School of the Royal College of Surgeons in Ireland. 2. The Carmichael School. 3. The School of Steevens 'Hospital. 4. The Ledwich School. 5. The Cecilia-street School.

An Annus Medicus may be kept in three ways—1. By attending two winter courses. 2. Or one winter and two summer courses. 3. By nine months' attendance on Sir Patrick Dun's Hospital and Clinical Lectures : together with one winter course or two summer courses of three months' duration.

The fee for nine months' attendance at Sir Patrick Dun's Hospital is twelve guineas.

The fee for the *Liceat ad Examinandum* is £5.

The fee for the degree of M.B. is £11.

Doctor in Medicine.

A doctor in medicine must be M.B. of at least three years' standing, and requires no other qualification.

Total fees for this degree, £13.

Master in Surgery.

This degree can only be obtained by Bachelors of Arts. The curriculum is the same as that for the Licentiate in Surgery, as given below.

Candidates will also be required to perform surgical operations on the dead subject.

Total amount of fees for the degree of Ch.M., £16.

Licentiate in Medicine.

Candidates for the licence in Medicine and Surgery must be matriculated in Medicine, and must have completed four years in medical studies, and must pass an examination in Arts, including Greek, Latin, English, and Mathematics, unless they be students in the Senior Freshman, or some higher class. The medical course necessary for a Licence in Medicine is the same as for the degree of M.B. A fee of £5 is charged on taking the Licence. Licenciates in Surgery of the Royal Colleges of Surgeons, on passing the Art Examination, will be admitted to examination for the Licence in Medicine. Such candidates will be exempted from examination in Anatomy and Surgery : Fee for the *Liceat ad Examinandum*, £5. Fee for the Licence in Medicine, £5.

Licenciate in Surgery.

Candidates must have kept one full year in Arts, and will be required to perform surgical operations on the dead subject. The curriculum extends over four years, and is as follows :—Two courses each of Anatomy and Physiology, and Theory and Practice of Surgery ; three courses of Demonstrations and Dissections ; and one course each of Practice of Medicine, Chemistry, Materia Medica, Midwifery, Laboratory Chemistry, Botany, and Medical Jurisprudence. Also attendance for three Sessions, each of nine months, on a recognized hospital. Of the courses of lectures, which are of six months' duration, not more than three can be attended during any one session. Any of the above-named courses may be attended at any of the medical schools at Dublin, provided the candidate has kept an *Annus Medicus*. A fee of £5 is charged for the licence, and £5 for the *Liceat*.

SESSIONAL EXAMINATIONS.

Candidates for degrees and licences will be subjected to two examinations, one of them preliminary, which will be held at the close of the second year, and the other, after the full curriculum has been completed. The subjects of the preliminary examination are the following : Descriptive Anatomy, Botany, and Materia Medica, Pharmacy, Chemistry, theoretical and practical, with Chemical Physics. The best answers at the preliminary examinations will be elected to the scholarships, provided they are in the Senior Freshman, or some higher class, and have kept one *Annus Medicus*.

PRIVILEGES OF MEDICAL STUDENTS.

Medical students, being junior or senior sophisters, and in attendance on the full courses necessary for an *Annus Medicus*, are exempted from the classics of the junior sophister year, and from one of the three optional courses (Mathematical Physics, Experimental Physics, or Classics) of the senior sophister year. To obtain this privilege the student must be matriculated, and the certificate of his attendance on lectures be submitted to the senior lecturer.

FREE COURSES.

Students in Arts having their names on the College-books will be permitted to attend one course free of expense with the Professor of Botany, and to attend the lectures of the University Professors at half price.

MEDICAL SCHOLARSHIPS.

Two medical scholarships are given annually, value 20*l.* per annum each, tenable for two years, the examinations for which are held each year in June, in the following subjects :—Anatomy, Physiology, Chemistry, Materia Medica, and Botany.

Medical School Exhibitions.

The professors of the University school give three exhibitions annually : two senior, value 15*l.* and 10*l.*, open to all students who have been three years attending the school. The subjects being—Practice of Medicine, Surgery, Pathology, and Forensic Medicine.

One junior, value 15*l.*—the time and subjects of examination being the same as those for the medical scholarship.

Expense of obtaining the degrees of Bachelor in Medicine and Master in Surgery in the University of Dublin :—Lectures, 49*l.* 7s. ; Hospitals, 28*l.* 7s. ; Degree Fees, 32*l.*=109*l.* 14s. ; Private Tuition, say, 20*l.* ; Total, 129*l.* 14s.

N.B.—As no degrees in Medicine or Surgery are conferred except upon graduates in Arts, the expense of the degree of Bachelor in Arts, amounting altogether to 83*l.* 4s., should be added to the foregoing, making the total cost something over 200*l.*

The Board of Trinity College have recently passed orders :—1. That three-fourths of the courses of lectures must be in all cases attended. 2. That the system of perpetual pupils be abolished. 3. That a daily roll be called by each Professor. 4. Students in Arts shall be entitled to attend one course in Botany, and to receive a certificate free of charge. 5. Candidates for degrees and licences in Surgery shall be required to attend one course only on Anatomy, for which he shall be charged three guineas. 6. The two courses delivered by the Professor of Surgery shall include practical instruction in Operative Surgery on the dead subject : and for each the professor shall charge four guineas. 7. The Professor shall

charge three guineas for the winter lecture in Chemistry. 8. Laboratory instruction shall be substituted for the second course of chemistry, hitherto delivered, for which the Professor of Chemistry shall charge five guineas. 9. Students in Arts may attend the Professors of Surgery and Chemistry, and to receive certificates on payment of half the fees. 10. That after Shrovetide, 1868, all candidates in Medicine shall produce certificates in practical Midwifery, incuding at least six deliveries.

See advertisements of School of Physic and Sir Patrick Dun's Hospital.

THE QUEEN'S UNIVERSITY IN IRELAND.

FACULTY OF MEDICINE.

DEGREE OF DOCTOR OF MEDICINE.

Each candidate for the degree is required—

1. To have passed in one of the Queen's Colleges the examination for Matriculation in Arts,* and to have been Matriculated in Medicine. 2. To have attended in one of the Queen's Colleges, Lectures on one Continental language for six months, and on Natural Philosophy for six months. 3. To have attended, in some one of the Queen's Colleges, two other courses of the medical curriculum. For the remainder of the courses, certificates will be received from the Lecturers in Schools, recognized by the Senate. 4. To pass two University Examinations—the First University Examination and the Degree Examination.

The curriculum of Medical study extends over four years, and is divided into two periods of two years each.

The first period comprises attendance on Chemistry, Natural History, Anatomy and Physiology, Practical Anatomy, and Materia Medica. Practical Chemistry in a recognized Laboratory is also to be attended during the first period, and the practice during six months of a Medico-Chirurgical Hospital, containing at least sixty beds, together with the Clinical Lectures delivered therein.

The second period comprises attendance on Anatomy and Physiology, Practical Anatomy, Theory and Practice of Surgery, Midwifery and Diseases of Women and Children, Theory and Practice of Medicine, Medical Jurisprudence. During this period Students attend Practical Midwifery, and eighteen months' practice of a Medico-Chiurgical Hospital, containing at least sixty beds, and in which clinical instruction is delivered.

At least two of the above courses of Lectures must be attended in some one of the Queen's Colleges; the remainder may be taken at the option of the candidate, in any University, College, or School recognized by the Senate of the Queen's University.

The University Examinations are held twice in each year, in June and September.

The June Examinations are Pass Examinations, and commence on the Tuesday following the second Saturday in June.

The Honour Examinations commence on the last Tuesday in September, and are followed by Pass Examinations.

Each candidate for examination in June must forward to the Secretary, before the 1st of June, notice of his intention to offer himself, along with his certificates; and each candidate for examination in September or October must forward similar notice, along with his certificates, before the 1st of September.

THE FIRST UNIVERSITY EXAMINATION IN MEDICINE.

The First Examination may be passed either in June or September.

Students may present themselves for this Examination at the termination of the first period of the Curriculum, or at any subsequent period.

Before being examined, each Candidate must produce evidence of having completed the course recommended for study during the first period.

The First University Examination comprises the subjects recommended for study during the first period, along with which any Candidate may present himself for Examination in Experimental Physics and Modern Languages, if he has attended in one of the Queen's Colleges the courses on these subjects.

* The following are the subjects of Examination. Homer's *Iliad*, Books I, II (omitting Catalogue of Ships), III: Lucian's *Dialogues* (Walker's edition); Xenophon's *Anabasis*, Books I, II, III; Virgil, *Æneid*, Books, I, II, III; Sallust; Horace, *Satires*; Latin Prose Compositon; English Prose Composition; English History; Modern Geography; Arithmetic; Algebra, to the end of Simple Equations; Euclid, Books I, II, III.

English Composition forms a part of all University Examinations.

HONOURS.

Competitors for Honours will be examined in all the subjects of the First Medical Examination, including Experimental Physics and Modern Languages.

Two Exhibitions, one consisting of two instalments of 20*l.* each, the other of two instalments of 15*l.* each, are awarded under certain conditions at this examination.

The candidates who pass with Honours will be arranged in three classes.

Candidates who defer passing their First Medical Examination until they present themselves at the degree examination are not eligible for Honours with the First Examination.

Honour and Pass Examinations are held in September. The Examination held in June is a Pass Examination.

DEGREE EXAMINATION IN MEDICINE.

Examinations for the M.D. will be held in June and September. The fee is 5*l.*

Each candidate must produce—

1. A certificate from the Secretary of the Queen's University, that he has passed the previous examination, unless he presents himself for both examinations simultaneously.

2. From the Council of his College that he has passed a full examination for Matriculation in Arts, and has been admitted a Matriculated Student in the Faculty of Medicine.

3. That he has attended in the College lectures on one Modern Language, on Experimental Physics, and two other courses.

4. That he has completed all other prescribed courses.

The Degree Examination comprises the subjects recommended for study during the second period, along with Experimental Physics and one Modern Language, unless an Examination in these subjects have been already passed at the previous Medical Examination.

The Examination for the Degree of M.Ch. comprises in addition an examination in Operative Surgery.

Candidates who graduated with Honours will be arranged in three classes. Candidates who take a first class will receive a medal and prize. Candidates who take a second class will receive a prize. Candidates who take a third class will receive a certificate of honour.

The examination for the Degree with Honours will commence on the last Tuesday in September, and will be followed by the examination of those candidates who seek to graduate without honours.

See advertisements of Queen's Colleges, Belfast and Cork.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Royal College of Surgeons is the principal Surgical Licensing Corporation of Ireland, and confers the great majority of the surgical qualifications granted in that division of the United Kingdom. Although there is a medical school attached to it, the College receives and grants its diplomas on certificates from all medical schools of standing. The letters testimonial confer the title of licentiate, with full qualification to practise; but the exercise of the privileges of attending and voting as a member of the College is reserved for Fellows. The Medical School of the College is under the superintendence of the Council, by whom the Professors are elected. Important modifications have been recently made in the system of examination, quarterly sessions of the court having been established, and voting by numbers instead of "Yes" and "No" introduced. Full information as to these changes will be found in the appended regulations. Operations on the subject are required to be performed by candidates for the diploma, and after January 1, 1871, clinical examinations will also be carried out.

REGISTRATION OF PUPILS.

Every person, and without any examination, shall be registered as a pupil on the college books on payment of five guineas, which is allowed in his diploma fee as part payment.

Registered pupils can study in the museum on two days in each week, and read in the library every day, from ten to one. They may also attend the Lectures on Comparative Anatomy, and obtain the certificate without payment. No student is admitted to the sessional or final examination for

letters testimonial until he becomes a registered pupil, but he may register at any time previous.

CLASSICAL EXAMINATION.

Students are admitted to this examination at any period previous to the final examination for letters testimonial.

The following are the subjects for the Preliminary Examination :—The English Language, including Grammar and Composition. Arithmetic, including Vulgar and Decimal Fractions. Algebra, including Simple Equations. Geometry, first two books of Euclid. Latin and Greek, including Translation and Grammar. In Greek—The Gospel of St. John, the Menippus of Lucian, or the First Book of Xenophon's Anabasis. In Latin—The First and Second Books of the Æneid of Virgil, the Jugurthine War of Sallust, or the Third Book of Livy. These examinations are hald quarterly, viz. :—On the third Wednesday in January, April, July, and October, in each year. Fee, ten shillings.

THE FELLOWSHIP.

Candidates must be twenty-five years of age, have studied six years, and have attended a course on Comparative Anatomy, on Botany, and Natural Philosophy. The fee is thirty guineas for a resident in Dublin, and twenty for a non-resident, having been previously a licentiate.

LETTERS TESTIMONIAL.

Every registered pupil shall be admitted to an examination if he shall have laid before the Council—*a.* A receipt showing that he has lodged twenty guineas. *b.* A certificate of an examination in Greek and Latin. *c.* Certificates of four year's study. *d.* Certificates of three years' hospital attendance.* *e.* Certificates of attendance on the following lectures :—

Three Courses.—Anatomy and Physiology; Theory and Practice of Surgery ; Dissections with Demonstrations.

Two Courses.—Chemistry (or one on general and one on practical Chemistry).

One Course.—Midwifery ; Medical Jurisprudence ; Botany; Materia Medica ; Practice of Medicine.

DIPLOMA IN MIDWIFERY.

Any Fellow or Licentiate shall be admitted to an examination upon the following documents :—

a. Certificates of one course of lectures on Midwifery and Diseases of Women and Children.

b. That he has attended a recognized lying-in hospital for six months ; or a recognized dispensary for lying-in women and children, devoted to this branch of surgery alone.

c. That he has conducted thirty labour cases. Candidates for the Midwifery Diploma shall be examined on the organization of the female ; the growth and peculiarities of the fœtus ; the practice of Midwifery, and the diseases of women and children.

The Candidate pays £1 6s. for the Midwifery Diploma provided he takes it out within one month from the date of his Letters Testimonial; after that date the Fee will be Two Guineas.

REGULATIONS AS TO EXAMINATIONS.

Letters Testimonial.

Five examiners at least are present. Each candidate shall be examined upon Anatomy, Physiology, the Theory and Practice of Medicine and Surgery, Materia Medica and the form of prescription, and shall perform such surgical operations or dissections, or explain such anatomical and pathological preparations as the examiners may require.

Licentiates of a college of physicians or graduates in medicine of a University, shall be examined in general and descriptive Anatomy, Physiology, the Theory and Practice of Surgery, and Operative Surgery. Rejected candidates cannot present themselves until after six months. In addition to the oral examinations, candidates are required to give written answers to written questions.

FELLOWSHIP EXAMINATIONS.

Five examiners at least, together with the president, or vice-president, and two members of the Council shall be present. Each candidate shall be examined on two days. The subjects of the first examination shall be Anatomy and Physiology (human and comparative) ; those of the second, Pathology, Therapeutics, the Theory and Practice of Medicine and Surgery. In addition to the oral examinations, candidates shall be required to give written answers to written questions. The candidates shall also perform dissection and operations on the dead body. Rejected candidates cannot present themselves until after one year.

ORDER OF QUARTERLY EXAMINATIONS.

1st. Candidates shall return their names to the Registrar, and lodge their fees and certificates one week before examination.

2nd. Candidates shall be examined in alphabetical order.

WRITTEN EXAMINATION.

3rd. The candidates assemble at three o'clock P.M., when twelve, selected according to alphabetical order, will each (for the junior class) receive three written questions on Anatomy and Physiology, and one on Materia Medica, and (for the senior) four written questions on Surgery and Practice of Medicine, which they will be required to answer within one hour ; at the end of the hour each candidate shall enclose his questions and answers in an envelope, with his name on the back, and hand same to the examiner superintending.

ORAL EXAMINATION.

4th. The seven examiners shall attend on each day at four o'clock, to commence the Oral Examinations, and four of them shall examine for a quarter of an hour, at four separate tables in the junior class—viz., three on Anatomy and Physiology, and one on Materia Medica, and in the senior class, three on Surgery and Practice of Medicine, and one on the form of prescriptions.

5th. Two councillors shall be summoned to witness the examination of each candidate, and shall accompany him from table to table till his examination be completed, when the voting papers having been examined, and the result declared, the name of each successful candidate shall be enrolled in a book kept for that purpose in the College.

Examinations shall be held on the fourth Tuesday in January, April, July, and October, at which candidates shall be divided into two classes—junior and senior.

Curricula.

The Junior Class shall produce certificates of three courses of Lectures on Anatomy and Physiology, three courses on Practical Anatomy, with dissections ; two courses on Chemistry, one course on Materia Medica, one course on Botany, and one course on Forensic Medicine.

This class shall be examined in Anatomy, Physiology, and Materia Medica.

The Senior Class shall produce certificates of three courses on the Theory and Practice of Surgery, one course on the Practice of Medicine, and one course on Midwifery ; also of attendance at a recognized hospital for three Winter and three Summer Sessions.

This class shall be examined in Surgery, Operative Surgery, the Practice of Medicine, and form of prescription.

6th. The examinations in Operative Surgery are conducted by the four surgical examiners. The questions are written upon cards, deposited in a balloting-box, from which each candidate, as called up, draws his question, and performs the operations there indicated.

7th. Any candidate rejected in Operative Surgery is not permitted to present himself for the senior *viva voce* examination.

Both these examinations shall be partly written and partly oral.

The fee for this examination shall be fifteen guineas.

Fees to be paid by Candidates for Letters Testimonial.

1st. The candidate pays ten shillings for his preliminary examination.

2nd. Five guineas as registered pupil of the College.

3rd. Five guineas for the Junior Class examination, which is not returned in case of rejection, but is allowed in the fee for his second examination.

4th. Fifteen guineas for the Senior Class examination—total, £26 15s.

* ATTENDANCE ON PROVINCIAL HOSPITALS.—Candidates who shall have attended recognized hospitals during three Winters, shall be admitted, if they shall produce certificates of attendance during a like number of months at a County Infirmary, or Provincial Surgical Hospital, containing at least fifty beds, provided the surgeons shall make returns in the months of May and November of the number of students so attending.

5th. Every candidate rejected at the quarterly examinations shall be required to pay to the College the sum of two guineas on applying for re-examination.

6th. The Registrar receives £1 1s. on handing over the diploma.

See advertisement of school in connection with College.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

REGULATIONS RELATIVE TO THE LICENCE IN MEDICINE.

EXAMINATIONS are held on the second Wednesday in each month.

The name of every Candidate, together with his Schedule and the essential documents must first be submitted to the College on the first Friday in each month, and no name can be received later than the Monday previous.

REGULATIONS RESPECTING THE LICENCES IN MEDICINE AND MIDWIFERY.

Candidates who have not obtained some of the qualifications of preliminary examination must give proof of four years' study; and of having studied Anatomy and Physiology, Practical Anatomy, Chemistry, Practical Chemistry, Materia Medica, Botany, Medical Jurisprudence, Practice of Medicine, and Pathology, Surgery, Midwifery.

Of having attended a Medico-Chirurgical Hospital, with Clinical Lectures, for twenty-seven months.

Of six months' Practical Midwifery at a hospital, or other evidence of having attended Practical Midwifery.

Testimonials of character from two registered Physicians or Surgeons.

A Candidate who has already obtained a Medical or Surgical Qualification is required to fill up a Schedule; but he is only required to produce his Diploma or Certificate of Registration, and the Certificate of Practical Midwifery, and Testimonials as to character.

The examination is by written questions, and *Viva Voce*, and divided into two parts:—

First part.—Anatomy, Physiology, Botany, and Chemistry.

Second part.—Materia Medica, Practice of Medicine, Medical Jurisprudence, and Midwifery.

Candidates qualified as follows are required to undergo the second part only—viz., 1. Graduates in Medicine of a University. 2. Fellows, Members, or Licentiates, of the Colleges of Physicians of London or Edinburgh, admitted upon examination. 3. Graduates or Licentiates in Surgery. 4. Candidates who, having completed the curriculum, shall have passed the previous examination of any of the Licensing Corporations in the United Kingdom.

Under this last regulation gentlemen who have passed the first portion of the examination for the Licence of the Royal College of Surgeons of Ireland or the Royal College of Surgeons of England are exempted from the first part of the examination.

Candidates who have been five years in practice are not required to undergo the written portion of the examination.

REGULATIONS RELATIVE TO THE DIPLOMA IN MIDWIFERY.

Examinations for the Diploma in Midwifery are held on the day after the Licence in Medicine.

Candidates not being Licentiates will be admitted on the following qualifications:—The Degree or Licence in Medicine or Surgery, with a Certificate of six months' Lectures on Midwifery, with six months at a recognized lying-in Hospital, or of having attended Practical Midwifery for six months at a recognized lying-in Hospital, or other evidence of having attended Practical Midwifery.

FEES FOR LICENCE AND EXAMINATIONS.

The Fee for the Licence is £15 15s.

The Fee for the Midwifery Diploma is £3 3s.

The Fee for the Licence in Medicine and Diploma in Midwifery, if taken out within one month, £16.

Further information and blank schedules may be obtained by application personally, or by letter, to the Registrar, College of Physicians, Kildare street, Dublin.

THE APOTHECARIES' HALL OF IRELAND.

REGULATIONS REGARDING THE LICENCE.

EVERY candidate is required to undergo a preliminary and a professional examination.

THE PRELIMINARY EDUCATION AND EXAMINATION

Include—1. English; 2. Mathematics; 3. French; 4. Latin; 5. Greek; 6. Natural Philosophy; 7. Natural History.

A preliminary examination will be held at the Hall four times in the year—viz., on the third Friday in the months of January, April, July, and October, at two o'clock P.M. This examination will be conducted by printed papers and written answers, and conducted by graduates in Arts of the University of Dublin, with assessors from the Court of the Hall.

Unsuccessful candidates will not be re-admitted to examination until after six months.

Certificates in Arts granted by any of the bodies named in the Medical Act, or by any educational institution approved of by the Medical Council, will be recognized.

The Apothecaries Company of Ireland was incorporated as the Pharmaceutical Licensing Body of Ireland. It practically abrogated that function some years ago by converting its Licence into a Medical Diploma. As no more than twenty persons out of the whole number qualified last year in Ireland took the L. A. H., and as it is expected that the Pharmacy Act of England will be shortly extended to Ireland, and the Examination in Pharmacy placed in the hands of the Pharmaceutical Society, we do not consider it necessary to occupy our space at length with the official regulations of the Apothecaries' Hall.

Every candidate must produce certificates:—1. Of having passed an examination in Arts previous to professional study. 2. Of being twenty-one years of age, and of good moral character. 3. Of apprenticeship to a qualified apothecary, or of having been engaged at practical pharmacy with an apothecary for three years subsequent to having passed the examination in Arts. 4. Of having spent four years in professional study. 5. Of having attended the following courses—viz.:—Chemistry, one winter session; Anatomy and Physiology, two winter sessions; Demonstrations and Dissections, two winter sessions; Botany and Natural History, one summer session; Materia Medica and Therapeutics, one summer session; Practical Chemistry, three months; Principles and Practice of Medicine, one winter session; Practical Midwifery at a recognised hospital (attendance upon twenty cases); Surgery, one winter session; Medical Jurisprudence, one summer session; Instruction in the Practice of Vaccination. Of having attended at a recognised hospital the Practice of Medicine and Clinical Lectures during two winter and two summer sessions; also the Practice of Surgery and Clinical Lectures, one winter and one summer session. 7. Of having performed vaccination under a recognised vaccinator.

CERTIFICATE OF ASSISTANT.

The Licence Examination is divided into two parts:—First, Chemistry, Botany, Anatomy, Physiology, Materia Medica, and Pharmacy. Second—Medicine, Surgery, Pathology, Midwifery, Forensic Medicine, and Hygiene. The First Part may be undergone after the second Winter and after the Candidate has attended Courses on the subjects named for this Examination; and the Second after the completion of his studies.

A candidate for the certificate of assistant to an apothecary must have completed at least three years of his apprenticeship, or have a certificate from an apothecary of having been engaged at practical pharmacy for three years, together with a certificate of good moral character.

The examination of the intended assistant will be restricted to the British Pharmacopœia and to Pharmacy, scientific and practical, including the history and character of medicines, their preparations, combination, and doses, and the translation of Latin prescriptions.

THE PROFESSIONAL EXAMINATION.

The Professional Examinations will be held quarterly, and will commence on the first and second Mondays in the months of January, April, July, and October. They will be carried on as follows:—The First Part, for Junior Students, by papers, on the first Monday, at twelve o'clock, noon; and orally, on the Tuesday and Wednesday succeeding, at the same hour. The Second Part, or Pass Examination for Senior Students, by papers, on the second Monday, at twelve o'clock, noon; and orally, on the Tuesday and Wednesday succeeding, at the same hour.

Candidates who fail to pass the first part of the professional examination will be remitted to their studies for *three months*.

Numerical values will be assigned to the Answers both written and oral, in the several Examinations, and only candidates who possess a certain proficiency of Medical knowledge in *all* the subjects will obtain "*the licence to practice.*"

Unsuccessful candidates at the Pass Examination will not be re-admitted until after the expiration of *six months.*

Doctors of Medicine of any University, or Surgeons of any College of Surgeons, who have served an Apprenticeship, or the required term at *practical* Pharmacy, to a qualified Apothecary, may obtain the Licence by undergoing one day's Examination—the former in Pharmacy and the latter in Medicine and Pharmacy.

Candidates for the *Licence* must lodge their Testimonials and enrol their names and address with the Clerk at the Hall, in Dublin, a week prior to the examination.

See the advertisement in another part of our issue.

Irish Hospitals and Schools of Medicine.

SCHOOL OF PHYSIC, UNIVERSITY OF DUBLIN.

This School was established by Act of Parliament 40 George III., and is under the joint government of the Board of Trinity College and the King and Queen's College of Physicians.

Institutes of Medicine, Professor Law. Materia Medica and Pharmacy, Professor A. Smith. Surgery, Professor R. Smith. Anatomy and Chirurgery, Professor MacDowel.

Its Medical School is at Trinity College, where a spacious dissecting-room has recently been erected. Information as to the Medical Scholarships and Exhibitions in this School will be found amongst the regulations of the University of Dublin.

For further particulars see advertisement.

SCHOOL OF SURGERY, ROYAL COLLEGE OF SURGEONS.

This School is under the superintendence of the Council of the College, who appoint the professors. The Introductory Address will be given on the first Monday in November. The Professor of Physiology will commence his course with a series of twelve lectures on Comparative Anatomy—free to the public. The dissecting-rooms have been recently much enlarged. Arrangements have been made to give increased facilities for instruction in Operative Surgery and Chemical Analysis. Prizes in Anatomy and Physiology, and Surgery, will be awarded at the end of the Winter Session. The Junior Surgical Society meets fortnightly in the school, and several prizes have been offered for the best essays read during the Session.

For further particulars see advertisement.

THE LEDWICH SCHOOL OF MEDICINE, PETER STREET.

This School, claiming priority of foundation before any of its kindred unchartered institutions were projected, was established in 1810 by J. Kirby, and has, since then, under the energetic administration of the Messrs. Ledwich and Dr. Mason, maintained a very high prestige as an educational institution. It is situated next door to the Adelaide Hospital in Peter street, about five minutes' walk from the Meath Hospital, Royal College of Surgeons, and Mercers' Hospital, and the Coombe Lying-in Hospital, and ten minutes from the Catholic University School, the University and the City of Dublin Hospital. The hospital in most immediate connexion with it is Mercer's.

For further particulars see advertisement.

STEEVENS' HOSPITAL SCHOOL.

This hospital is conducted on the plan of the London Hospital Schools, combining, in one establishment, all the departments of medical education. Situated in the centre of a district occupied by some of the largest manufacturing concerns, its beds are constantly filled with accidents of a serious nature. Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane, Dr. Croker, consulting physician, being one of the medical attendants. All morbid specimens are most carefully examined and preserved by the curator, who is an officer regularly appointed and paid by the Board of Governors.

There is accommodation for residence of seven surgical and four medical residents; besides whom the Resident-Surgeon receives house pupils. The fees payable for the privilege of residence are 21 guineas, winter; 15 guineas, summer six months; including hospital ticket; students have apartments, coal, gas, and furniture.

Accommodation outside the hospital, in the neighbourhood, is arranged by the hospital authorities.

PRIZES.

3 Cusack Medical and Exhibition, of 8*l*, 5*l*, 3*l*; 2 Midwifery Assistants, 30*l* each; 1 Medical Clinical Prize, 10*l* 10s; 1 Surgical Prize, 10*l* 10s.

The session opens with the distribution of prizes in the first week in November.

For further particulars see advertisement.

THE CARMICHAEL SCHOOL OF MEDICINE.

The various lectures are now delivered, and the dissections carried on in the new building, which the munificence of the late Surgeon Carmichael has given to the proprietors. As the building was designed with special reference to the requirements of a large medical class, every convenience is afforded to the student in the prosecution of his studies.

The proximity of this School with the House of Industry Hospitals, and its connections with these institutions as well as with the Mater Misericordiæ, Meath, and Jervis street Hospitals, through its teachers, ensures equal opportunities to the pupils of becoming thoroughly acquainted with the more immediately practical part of their profession.

Arrangements have now been completed for rendering more available the Carmichael premium bequest, which will henceforth enable the proprietors to distribute prizes to the amount of 60*l*. yearly; and the Scholarship, value 15*l*. yearly, which the friends of the late Dr. Mayne have founded in his name, will be allotted at the termination of the Winter Session.

For further particulars see advertisement.

THE CITY OF DUBLIN HOSPITAL.

This hospital is situated in Upper Baggot street, about ten minutes' walk from the Royal College of Surgeons and the Medical School of Trinity College, and twelve from the Ledwich Schools and the School of the Catholic University. Physicians and surgeons are, with two exceptions, either Professors or Demonstrators in the School of the Royal College of Surgeons in Ireland. The hospital contains 104 beds, and accommodates about 800 intern patients annually. There are special wards for ophthalmic and aural diseases (on which subjects a special course of lectures is delivered by Dr. Loftie Stoney), and for diseases of children. A new wing has been lately opened for the reception of fever and other infectious diseases. The "Purser" Studentship of 20*l*. per annum (with apartments) is obtainable by competitive examinations by all students, and a special certificate is granted. The fees for hospital attendance are—nine months, 8*l*. 8s.; six months, 6*l*. 6s.; summer three months, 3*l*. 3s. Perpetual, 21*l*.

A special course of lectures on ophthalmic surgery is now required for the surgical qualifications of the University of Dublin.

For further particulars see advertisement.

THE MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

This hospital is situated about a quarter of an hour's walk from the University, and within a few minutes of the College of Surgeons and the Ledwich Schools of Medicine; affords every facility for the treatment and study of disease. Its salubrious position and long-established character call for constant admission to its accident, chronic, fever, surgical, and children's wards, which are thus constantly occupied with cases illustrative of medicine and surgery.

Four prizes will be given at the termination of the winter course to the best answerers in their respective classes.

The office of resident pupil is open to pupils as well as apprentices.

For further particulars see advertisement.

ST. VINCENT'S HOSPITAL.

This hospital was established in 1834 by the Sisters of Charity, some of whom had studied the system of the Parisian hospitals, after which it was modelled. The ward for "*Enfans Malades*" is an interesting feature. The hospital has over a hundred beds constantly full, and each sister has charge of about twelve patients. In connection with it a Convalescent Home was established two years since at Stillorgan, the greatest benefit in the way of rapid recoveries and convalescence after acute attack has followed. These institutions are wholly supported by voluntary contributions. The clinical instruction in medicine and surgery is given by Dr. Quinlan, Dr. Mapother, Mr. O'Leary, and Dr. Cryan. Prizes are awarded at the end of the winter session.

For further particulars see advertisement.

THE ADELAIDE HOSPITAL

Is in Peter-street, next door to the Ledwich School. From the 1st of October, the physicians and surgeons will visit the wards, and give instruction at the bed-side, at the advertised hours, and the course of clinical lectures will be commenced in the beginning of November.

For further particulars see advertisement.

SIR PATRICK DUN'S HOSPITAL,

Founded on the endowment of Sir P. Dun. and for many years receiving nothing but purely medical cases, has been lately reconstituted as a Medico-Chirurgical Hospital. It is in immediate connection with the School of Physic, and its physicians and surgeons are all professors in that School. The University requires nine months' attendance at this hospital from candidates for the M.B.

Hospital fee for twelve months, including nine months' clinical lectures, nine guineas.

For further particulars see advertisement.

MERCER'S HOSPITAL.

Is situated within a few minute's walk of the Royal College of Surgeons, Ledwich School, Trinity College, and Catholic University School.

Wards for the reception of fever and contagious diseases are now open, in addition to the previous accommodation of the hospital.

Terms of Attendance.—Six months, six guineas; nine months, eight guineas; perpetual pupils, 21*l.*

For further particulars see advertisement.

JERVIS-STREET HOSPITAL.

This hospital is situated in the neighbourhood of the Carmichael and Catholic University Schools, and in a part of the city not otherwise provided with hospital relief.

For further particulars see advertisement.

ROTUNDO LYING-IN HOSPITAL.

This well-known institution is the largest and oldest maternity hospital in the United Kingdom, and the repute in which it is held attracts students from all parts of the world. It accommodates an average of 1,700 intern patients, including those admitted to the chronic wards labouring under the various forms of uterine complaints, and is under the care of the Master, who is elected every seven years, and two assistants, who hold these appointments for three years. The mastership is at present held by Dr. Johnston, and the assistants are Dr. Thomas More Madden, and Dr. Alexander Taylor. There is, in addition, an external maternity department, where patients, procuring a ticket properly signed, can be attended at their own homes; also, a dispensary is held every morning for diseases of women and children. Clinical instruction is given each morning both in the labour as well as in the chronic wards, and two courses of lectures are delivered in the year, which are recognized by all the licensing bodies.

A student entering for the practice of the hospital pays a fee of 10*l.* 10s. for six months. During that time he is required to attend at least thirty cases, either within the walls of the hospital or at the residence of patients who may apply for assistance. For this course of study, on examination, a diploma is given, which is received as a qualification in midwifery in the public services.

A limited number of students is admitted to reside in the hospital, for which they pay a fee of 20 guineas for six months.

COOMBE LYING-IN HOSPITAL.

This hospital was founded in 1826, but it was not till 1867 that it was incorporated by Royal Charter, which enables its medical officers to issue diplomas qualifying the holders to practise midwifery. By a clause in the charter the diplomas issued antecedent to its date have been made of equal force and value with those issued subsequent thereto. This hospital divides with the Rotundo almost the entire of the obstetric hospital practice of Dublin. It is situated in the centre of a district densely populated by the lower orders, and thus affords the amplest opportunities for practice. It accommodates about 600 labour cases within its walls, while those attended as externs amount to nearly double that number. Moreover, the chronic ward for the reception of cases of the diseases of females, gives admission to about eighty patients annually. Its wards are in the charge of Dr. Ringland and Dr. Sawyer, as masters, and Dr. Roe, as assistant master, whilst the chronic ward for the diseases of females is under the charge of Dr. Kidd, the obstetric surgeon of the institution. The fee for attendance is 4*l.* 4s for six months as extern, and 10*l.* 10s as as intern pupil. During that period the student attends on a given night in each week, or oftener, if circumstances permit, and takes charge in his turn of any cases that may be admitted to the labour wards, or may call for his assistance outside. In difficult cases he has the superintendence of the resident medical officer, and of the masters when necessary. An annual examination is held in May and November, at which prizes of considerable amount are awarded, and certificates of good answering granted. Two paid resident pupil midwifery assistantships are obtainable annually by competitive examination, for which all pupils who have obtained their midwifery diploma are eligible.

For further particulars see advertisement.

Provincial Colleges of Ireland.

QUEEN'S COLLEGE, BELFAST.

The first Matriculation Examination will commence in October. There will be additional Matriculation Examinations on the 14th November for those who have not been able to present themselves at the first. Lectures will commence on 1st November. No student can be permitted to enter after the 14th November. Two junior scholarships, value £25 each, are awarded to matriculated students commencing the first year of their study. The examination for these will take place immediately after the first Matriculation Examination. Two of similar value to students of the second year, two to students of the third year, and two to students of the fourth year.

For subjects of examination and other information see Queen's College Calendar for 1865. At the termination of the session, prizes will be awarded for proficiency in the several classes.

The trustees of the "Charters' Educational Fund" grant annually, for ten years, a sum of £50, for the purpose of establishing an exhibition in connection with the Belfast School of Medicine. The competitive examination for this exhibition will be held at the end of the session, at which all medical students can compete.

Fees.—Practical chemistry, 3*l.* Anatomy and physiology, first coursy, 3*l.*; subsequent course, 2*l.* Anatomical demonstrations and practical anatomy, each course, 3*l.*; for subjects each session, 15s. Other medical lectures, first course, 2*l.*; each subsequent course, 1*l.*

BELFAST GENERAL DISPENSARY.

This institution is the only hospital for the reception of injuries and surgical diseases in Belfast, and contains 150 beds.

For further particulars see advertisement.

QUEEN'S COLLEGE, CORK.

MEDICAL SCHOLARSHIPS.

First year.—One to the candidate who shall have most distinguished himself at the examination for science scholarships of the first year in Arts, and one to the candidate who shall have most distinguished himself at the examination for literary scholarships of the first year in Arts. Candidates for these scholarships shall have previously declared themselves, and have matriculated as medical students.

Subjects for the second year—Anatomy and physiology, chemistry, general physics, zoology and botany, the French language.

Subjects for third year—Anatomy and physiology, practical anatomy, materia medica, practical chemistry.

Subjects for fourth year—Anatomy and physiology, practical anatomy, therapeutics, pathology and morbid anatomy, surgery, midwifery.

The fees, whether matriculated or non-matriculated for attendance on lectures, are 1*l.* for each course, when attended for the first time, and 1*l.* for each re-attendance on the same; except that the fee for anatomy and physiology shall be 3*l.* when attended for the first time, and 2*l.* for every subsequent attendance; and that for practical anatomy or practical chemistry shall be 3*l.* for each attendance.

For further particulars see advertisement.

QUEEN'S COLLEGE, GALWAY.

FACULTY OF MEDICINE.

The College Session.

The College Session is divided into three terms. The first term commences October 19th.

Matriculation.

The Matriculation Examination is held at the commencement of the first term; but additional examinations are held before the close of the term. The last Matriculation Examination is held on the 16th November. Each candidate before being admitted to examination must pay a fee of ten shillings, which will be returned to such as fail to pass.

Attendance on Lectures.

All students shall pay the College fee, and a moiety of their class fees, and enter their names with the Registrar, before they are admitted to the classes of the several Professors. No student shall have his name replaced on the rolls at the second term who has not paid the second moiety of his class fees. No student shall be regarded as having kept a course of lectures who has not attended two-thirds of the entire number.

Examinations.

A Sessional Examination is held at the close of each session in the subjects of lectures. There is also a Supplementary Examination on the same subjects at the commencement of the following session.

Scholarships.

Eight junior scholarships, of the value of 25*l.* each, are awarded to students pursuing the course for the degree of M.D. The examinations for junior scholarships are held at the commencement of the first term. Junior scholars are exempted from one moiety of the class fees. The College is empowered to award exhibitions, varying in value from 10*l.* to 18*l.*, at the same examinations as the scholarships, and to be held upon the same terms.

For further particulars see advertisement.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS, NORTH BRUNSWICK STREET, DUBLIN.

These Hospitals contain 312 beds; 110 for Surgical, 82 for Medical, 120 for Fever and other epidemic Diseases. The Truss Establishment, for the distribution of trusses to the ruptured poor of Ireland, is connected with these Hospitals. There is an extensive Pathological Museum, containing above 4,000 drawings, casts, and preparations, with the history of each case recorded. There is also a well-selected Medical and Surgical Lending Library. Two Clinical Lectures are delivered in each week, in addition to the usual Bed-side Clinical Instruction which is given daily by the Physicians and Surgeons. There will be a distinct Course of Lectures and Clinical Instruction on Fevers. A course of Practical Instruction in Ophthalmic Surgery, as required by the Board of Trinity College for Surgical Degrees, will be given. Surgical Operations are performed on Wednesday mornings only, except in cases of emergency. Eight resident Clinical Clerks and the Dressers are selected each half-year from among the best qualified of the pupils, without the payment of any additional fee. Eight *Interns* will be appointed on the 1st of November, and provided with furnished apartments, fuel, &c., &c. At the termination of the Session, premiums will be awarded in Clinical Medicine and Surgery. The Richmond Institution for the Insane, containing 1,000 beds, adjoins these Hospitals, affording every facility for the study of mental diseases. The Carmichael School of Medicine, in which all the Courses of Lectures required by the different Colleges are delivered is in the immediate vicinity of these Hospitals; the student is thus furnished with every facility for completing his professional education.

RELATIVE COST OF MEDICAL EDUCATION IN IRELAND.

University of Dublin, M.B. and M.Ch.

	£	s.	d.
I. Lectures	49	12	0
II. Hospitals	33	12	0
III. Degrees	32	0	0
	115	4	0
Expense of Degree in Arts	83	4	0
Total	£198	8	0

Queen's University M.D. and M.Ch.

If two years' Lectures and Hospital be taken in Dublin, about	£67	0	0

Colleges of Surgeons and Physicians.

About	£140	0	0

On these terms a reduction may be made by cash payments to Hospital and College at the commencement of study.

Scottish Institutions.

We now turn to the various bodies in Scotland. First, as to the Universities.

University of Edinburgh.—This is a teaching as well as a qualifying body, and the other faculties are as complete as that of medicine. The University confers the degree of M.D., and M.B., as well as that of C.M., and so affords its graduates the opportunity of obtaining, at the same time, a Surgical, in addition to the Medical diploma. The C.M. is not conferred on any one who does not take at the same time the M.B. For the degrees of M.B. and C.M., four years of professional study must be completed after passing a preliminary examination recognized by the Medical Council. A degree in Arts in any British University exempts from the preliminary examination. Of these four years, one must be passed in the University of Edinburgh, and one other either in that or some other University entitled to confer the degree of M.D.

The University recognizes the courses of lectures of extra-academical teachers in Edinburgh, subject to certain regulations.

University of St. Andrew's.—This University confers the Degree of Master in Surgery (C.M.), as well as the Degrees of Bachelor and Doctor of Medicine. For many years the University did not require residence, and large numbers of medical men resorted to it in order to obtain the Doctorship by examination only. In this the University closely assimilated itself to the University of London, which is exclusively an examining body. The large number of practitioners who obtained the Degree after an examination extending over three or four days, attests the wisdom of a policy which was almost reversed by the University Commissioners. Only ten persons per annum can now obtain the St. Andrew's Degree without residence. There are not a few of the old graduates who look upon this policy as retrograde and illiberal. The University of London maintains its position without requiring academical residence, and no one can doubt that the University of St. Andrew's might have pursued the same course with great success, and by so doing conferred a benefit on the profession. Those who have not now fulfilled their course in a University must either go to the University of London or forego a degree. The London University compels matriculation before commencing Hospital study. Only a relaxation of this rule can secure to all who desire it the opportunity of being examined for a degree.

University of Aberdeen.—This is a large teaching body, as well as one entitled to confer degrees in all the faculties. The curriculum required for medical degrees is the same as that of the University of Edinburgh. Thus four years of professional study, after passing a preliminary examination, is essential. One year must be passed at Aberdeen. The lectures qualifying for this and other examining bodies are delivered by the Professors in the University.

University of Glasgow.—This is a large teaching as well as examining body. The same degrees are conferred as in the Universities of Edinburgh and St. Andrew's. The course of study and regulations to be served by candidates are the same as those of the University of Edinburgh, one year's compulsory residence at the University of Glasgow being required instead of at Edinburgh. The examinations are conducted by the Professors of Medicine, together with the three Assessors appointed by the University Court. The fees for degrees in all four of the Scottish Universities are uniform—viz.: M.B., 15*l.* 15s. (being 5*l.* 5s. at each of the three examinations); C.M., 5*l.* 2s. (in addition to the fees for M.B.); M.D, 5*l.* 5s. (in addition to the fees for M.B.); and 10*l.* 3s. for Government stamp. The lectures qualifying for the degrees are delivered by the Professors in the University, and the hospital practice is attended at the Glasgow Royal Infirmary.

Now as to the Corporations.

Royal College of Physicians of Edinburgh.—This, like its London sister, is exclusively a licensing body, though, since the arrangement for the double qualification has been carried out, it may possess some additional control over the teaching at Surgeons' Hall. By this arrangement students who have fulfilled the prescribed curriculum may pass the joint examination of this College and the Royal College of Surgeons, and obtain the two diplomas. They can thus at once register both a medical and surgical qualification.

THE FELLOWSHIP.

This is conferred only by election, and no one can be balloted for until he has been a member for one year.

THE MEMBERSHIP

Is conferred on licentiates of a College of Physicians, or graduates of a University, who are 24 years of age, and satisfy the College of their knowledge of medical and general science.

THE LICENCE.

The regulations are the same as those for the joint examination for the Scotch Double Qualification, with the following exceptions:—Anatomy, Practical Anatomy, and Surgery, six months; Clinical Surgery, three months.

Candidates for the Licence of the College who already possess a qualification from a recognised licensing body, or who have passed the first Professional Examination before a qualifying body, will not be required to be re-examined in Anatomy, Physiology, and Chemistry.

The following are the Fees, payable in all cases in advance:—

By a Licentiate, Ten Guineas. By a Member, Thirty Guineas.

When a Licentiate shall be raised to the rank of Member, Twenty Guineas.

Royal College of Surgeons of Edinburgh.—The Fellowship is conferred only on persons who have obtained a diploma from this or one of the Colleges of Surgeons of England or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, and who are 25 years of age. At the election, three-fourths of the votes are required to be in the candidate's favour, and he has to maintain the privileges of the College and obey its laws. Fellows are forbidden to keep open shops, to be connected with secret remedies, or to suffer their names to be used in indelicate advertisements or publications.

THE LICENCE.

The regulations are the same as those for the Joint Examinations, conducted by the Colleges of Physicians and Surgeons, with the following exceptions:—Botany is not required. A second course of Medicine is not required.

The first Professional Examination embraces Anatomy, Physiology, and Chemistry. The second, Surgery and Surgical Anatomy, also Medicine, Midwifery, Materia Medica, Medical Jurisprudence, and Clinical Surgery.

Registered medical practitioners, whose degree or licence in Medicine dates prior to October 1st, 1861, are exempt from the first Professional Examination.

Fee for the diploma, £10.

Faculty of Physicians and Surgeons of Glasgow.—This body has similar powers to those of the Royal College of Surgeons of Edinburgh, and its regulations for Licence and Fellowship are similar. It has also the same arrangement with the Edinburgh College of Physicians for a double diploma.

The Scotch Double Qualification.—As already stated, the Royal College of Physicians of Edinburgh have made arrangements with the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, by which, after one series of examinations, the successful candidate receives two diplomas, and is thus able to register a medical and a surgical qualification under the Medical Act, thus:—

Lic. Roy. Coll. of Phys. Ed., and Lic. R. C. S. Edin., or Lic. R. Coll. of Phys. Ed., and L. Fac. Phys. and Surg. Glas., as the case may be.

The principle on which the joint examinations are conducted is a simple compromise by which the College of Physicians takes exclusive charge of the examination in medicine; the College of Surgeons or the Glasgow Faculty, as the case may be, of the examination in surgery; while the examination in subjects common to both medicine and surgery is conducted by a Board, in which each of the bodies is represented.

It is proper to state that such arrangements as those were contemplated by the Medical Act and authorised by Section XIX., while those under consideration were sanctioned by the Medical Council on the 7th August, 1859.

Candidates for the double qualification having fulfilled the prescribed curriculum are subjected to two profes-

sional examinations. The preliminary examination for future students must be passed before commencing professional study, and in other respects be in accordance with the recommendations of the Medical Council.

Anderson's University, Glasgow.—This is exclusively a teaching body. It offers excellent opportunities for acquiring a complete medical education, and the expenses are very much below those of any other institution. The fame of Glasgow as a place for clinical instruction has long been known, and this school affords the means of dissection, and the pursuit of other practical knowledge throughout the year. Hospital practice at the Glasgow Royal Infirmary. Every information will be given on application to Dr. McCall Anderson, 1 Woodside crescent, Glasgow, both as to the University, the Hospital, and Diploma.

THE GENERAL MEDICAL COUNCIL.

To this body is entrusted the supervision of medical education, and it has made a number of recommendations, the majority of which have been accepted by all the Examining Bodies, and are, consequently, found in their regulations. The student has, therefore, nothing to do with the Council, except that he must take care to be duly registered as a student of medicine, at the commencement of his career, at the office, Soho Square.

MEDICAL REGISTRATION.

All duly qualified Physicians, Surgeons, Medical Graduates, and Apothecaries, are required by the Medical Act 21 and 22 Vic. c. 90, to be registered before they can hold any public medical or surgical appointment, or issue valid medical certificates.

The Medical Registration of any Practitioner may be effected, on application, in writing (according to a form to be had at the Office, 35 Dawson street, Dublin) and producing, or transmitting with such requisition the *Diplomas* to be registered, and also paying or remitting the fee which is regulated by the Medical Council, viz., £5 for first registration, and 5s. for every qualification which may be subsequently added. Drafts on Banks, and Post-office orders, to be drawn in favour of W. E. Steele, M.D., Registrar, Dublin.

Medical Students who have passed a preliminary *Arts Examination* are required by the Medical Council to be registered. In order to effect this each student should apply according to a form (to be had on application as above), accompanied by a certificate of his having passed such examination, same to be lodged with the Registrar (W. E. Steele, M.D.) who will thereupon enter the name in the Students' Register, and issue a certificate to that effect. *No fee* is required from *Medical Students* for *their* registration.

Public Services.

ARMY MEDICAL SERVICE.

The appointment of assistant-surgeon in the Army is open to all who can prove their claim to it by superior answering. The competitive examinations are held at Chelsea, usually in the first weeks of February and August. The candidate is not required to produce any other qualification before presenting himself for examination than his licences to practise and certificate of registration.

Having received his diplomas in surgery and medicine, both of which are essential to his competition, the student is obliged to apply himself vigorously to the study of certain collateral subjects, which he does usually through the medium of a "grinder." He must perfect himself in chemistry, pathology, and comparative anatomy, and if he can throw a proficiency in botany and natural history into the scale, he will materially improve his position in the scale of merit, and establish for himself a character with the authorities for industry and scientific attainments.

The assistant-surgeon is subjected to three separate examinations within the first ten years of his service, each examination having a definite object—the first, to ascertain, previous to his admission into the service as a candidate, his scientific and professional education, and to test his acquirements in the various branches of professional knowledge; the second, after having passed through a course of special instruction in the Army Medical School, to test his knowledge of the special duties of an army medical officer; and the third, previous to his promotion, to ascertain that he has kept pace with the progress of medical science.

The candidate having sent in his papers, and followed them to London, meets his competitors at Chelsea.

For the first two days of his examination he is employed in penning answers to printed questions; for the third and fourth days he is examined *vivâ voce* on all subjects; and on the fifth and sixth days he is tested by the diagnosis of disease at the bedside in the hospital, by the application of surgical apparatus, and by operations on the dead subject. This trial finished, the successful candidates (varying in number from fifteen to thirty) are selected.

SERVICE ON THE WEST COAST OF AFRICA.

A certain number of candidates, whose answering has been satisfactory, but not sufficiently so to entitle them to a place, are offered appointments on the West Coast of Africa. These situations, while they are subject to strong objection on the score of the deleterious nature of the climate, possess some advantages for those whose health can resist its influence. The districts comprised under the West Coast districts are Sierra Leone, Gambia, and Cape Coast Castle. If the candidate accepts the appointment he is sent out at once, without the period of probation to which others are subjected at Netley Hospital. He is allowed to spend a year at home, on full pay, for every year spent in Africa, and the entire period at home and abroad counts as service for pension. The promotion is sometimes rapid, owing to the dangerous nature of the climate; and we have known the rank of full surgeon reached in five years from the date of appointment as assistant-surgeon.

PROBATION AT NETLEY HOSPITAL.

The competitor who has been so fortunate as to obtain a place in the ordinary service is not allowed to join a regiment at once. He is obliged to undergo a probation of four months at Netley Hospital, near Southampton, where he is compelled to attend the following lectures—viz.: Hygiene, by Dr. Parkes; Pathology, by Dr. Aitken; Military Surgery, by Dr. Longmore; and Tropical Diseases, by Dr. Maclean. The lectures on Military Surgery include gunshot and other wounds; arrangements for the transport of wounded; duties of Army Surgeons in the field, during sieges, on transport, &c.; and other special subjects. Those on Military Medicine refer to the tropical and other diseases of the British possessions and colonies, and to the losses by disease. The lectures on Hygiene relate to the examination of water, air, food, clothing, &c., of the soldier; his duties and exercise, and the circumstances affecting his health, meteorology, statistics, and prevention of disease. The lectures on Pathology have reference chiefly to the scientific examination of tropical diseases, and of the other complaints which the Army Surgeon is especially called on to investigate. The candidates also attend the wards of the hospital under the Professors of Medicine and Surgery, to make

themselves acquainted with the system of recruiting, and the modes of keeping the Army Medical Returns. They are also called on to make *post-mortem* examinations, to operate on the dead body, and pass through laboratory practice on the modes of recognizing the qualities and adulterations of food, and on microscopic examination of morbid tissues and adulterations of food, &c. During his preliminary training here the student is understood to be in Her Majesty's service; he wears uniform, is under military discipline, and receives pay at the rate of five shillings per day, and two shillings per day for lodging money, if he be not provided with lodgings in the hospital. A sum of money equal to the half-yearly interest on £1,200, the surplus from the "Herbert Memorial," is at the end of each session awarded to the candidate who has the highest number of marks; the fortunate young man who wins this "Blue Ribbon of Netley" being tolerably certain to be well provided for. At the termination of the four months he is again examined in the subjects in which he has been instructed during that period, his marks are added to those obtained by him at the Competitive Examination, and his position on the list of merit determined by the total. Successful candidates are now eligible to be gazetted to a regiment, or employed on the staff, and enjoy all the rank and honour, pay and privileges, of Assistant-Surgeons, as provided by the regulations.

Thus it will be observed that the first, or Chelsea examination, simply admits the candidate to the service, and the conjoined result of it and the Netley examination determines his order of merit.

THE PROMOTION EXAMINATION.

But there is still one other which *must* be passed before he is promoted to full Surgeoncy, and *may* be passed at any time after five years' service.

A series of printed questions will be sent by the Director-General to the principal medical officers of stations where Assistant-Surgeons may be serving, who will deliver these sealed questions to the Assistant-Surgeons, and to see that they are answered without the assistance of books, notes, or communication with any other person. The answers are to be signed, and delivered sealed to the principal medical officer, who is to send them, unopened, to the Director-General, together with a certificate from the Surgeon of the Regiment, or other superior medical Officer, that the Assistant-Surgeon has availed himself of every opportunity of practising surgical operations on the dead body.

The Assistant-Surgeon will also be required to transmit a Medico-Topographical account of the station where he may happen to be, or of some other station where he may have been resident, or else a Medico-Statistical report of his regiment for twelve months.

If the Examining Board and the Director-General are satisfied with the certificates and answers, and with the report, the Assistant-Surgeon will be held qualified for promotion.

NAVAL MEDICAL SERVICE.

In applying to be admitted as an assistant-surgeon in the Royal Navy it is merely required to address a letter to the Secretary of the Admiralty, stating that you are in possession of a diploma from such a College—naming it; that you are desirous of being admitted as a candidate; when, if there are any vacancies, you will be informed when you will be required to present yourself at Somerset House, London, for examination.

Having passed your examination, you will, in the course of the following day, receive your appointment as acting assistant-surgeon to one of Her Majesty's ships, either for service on board that ship, or for service on shore, at one of the naval hospitals—Haslar or Plymouth. You will at the same time be informed that you are granted two or three weeks, as you may require, leave of absence, to enable you to provide your uniform and appointments. These you can get at any of the naval outfitters.

The expense of an assistant-surgeon's uniform is about £47 5s. These are credit prices, but would, I presume, be considerably less for ready money, a thing, by-the-by, to which naval tailors are not much accustomed. You must also provide yourself with a set of surgical instruments, which will cost you from ten to fifteen guineas. All kinds of underclothing, towels, handkerchiefs, &c., may be purchased much more advantageously from a regular dealer in those things than from any naval outfitter.

ADVANCE OF PAY ON JOINING.

On joining your ship you will, if you wish it, be paid what is termed three months in advance, £30. Of course it is not all advance, as your pay will have been going on from the date of your appointment.

Every article of mess traps is now furnished by the Admiralty gratis. The same with your cabin furniture; every necessary article except bedding is supplied from the dockyards. An officer on joining his ship has, therefore, nothing more to pay than his mess subscription monthly. This varies in ships according to the station they are on, from £2 10s. to £3 10s. per month. This subscription does not include anything for wines or liquors of any kind. Whatever amount of these you may consume will be paid for by you separately, at the end of each month or quarter. But as all wines are permitted, by sanction of the Admiralty, to be shipped free of duty, you drink them so much cheaper on board than you could the same qualities of wine on shore. The monthly subscription, of say £3, with the Government allowance of £11 3s. 8d. per annum to each member in lieu of provisions, is generally found sufficient to meet all ordinary expenses of messing.

It is the custom in all wardroom messes to have an extra dinner on two days of the week—generally Monday and Thursday. The days so selected are styled "field-days." It is on these days that guests are invited to dine by the mess. The guests thus invited are called public guests, and such invitations entail no extra subscription from any one, except for the extra wine consumed. It is usual to invite the captain, and other superior officer that may be on board, once a week; the other public guests are so many of the junior officers of the ship; and, if in port, officers of the sister service, and other public functionaries. The captain, or admiral, if there be one on board, usually has two or three wardroom, and two or three gunroom officers, to dine with him on every other day of the week than that on which he dines in the wardroom. Any member of the wardroom mess inviting a private friend to dine with him on board, pays usually from 2s. 6d. to 3s. 6d. (according to the rule of the mess) for his friend's dinner, in addition to any extra expense for wine.

The foregoing are the whole of the ordinary and extraordinary expenses of messing in the wardrooms of Her Majesty's ships, and which should not, with drinking a reasonable quantity of wine, beer, &c., exceed fifty guineas per annum.

Officers in the Navy, wherever they may be serving, can remit, by the paymaster of the ship, without any expense, any portion, or the whole, of their pay that may be due to them on the last day of each quarter.

SERVANTS.

Assistant-surgeons are allowed only half a servant each; or, in other words, a servant between two of them.

These servants are entered on the ship's books with the rating of officer's servant. Their pay from the Admiralty is about £17 per annum and their provisions; and where they are well conducted, attentive lads, it is usual for each of their masters to give them 10s. a month, which makes their pay up to about £29 per annum.

The pay of naval medical officers has hitherto been the same as for their military brethren.

EXTRA PAY AND ALLOWANCES.

The following extra pay and allowances are paid to naval medical officers under the conditions stated below :—

	At Home.	Abroad.
Inspectors-General, in lieu of provisions for their servants, and of the ordinary allowance for provisions for themselves	£54	£130
Deputy Inspectors-Generals Staff-Surgeons and Surgeons, do. do. ..	£35	£112
Assistant-Surgeons, do. do. ..	£30	£108

Staff-surgeons, when serving in flag-ships on foreign stations, are allowed extra pay of five shillings per diem.

Staff-surgeons, surgeons, and assistant-surgeons, when serving in ships in which there is no accommodation for residing on board, as in drill ships for the Royal Naval Reserve, are allowed £50 per annum for lodgings, and one and sixpence per diem in addition in lieu of ship's rations.

Whenever medical officers are employed on extra duty, they are allowed such extra pay as it may appear to the Lords Commissioners of the Admiralty the nature of the service merits.

Medical officers, when travelling on the public service, are allowed on the home stations—in addition to all expenses of first class fare by rail or otherwise—for subsistence :—

	Special Service occupying 12 hours.	Ditto for every 24 hours.
Inspector-General and Deputy Inspectors-general	£0 12 0	£1 0 0
Staff-Surgeons and Surgeons ..	0 7 6	0 10 0
Assistant-Surgeons	0 6 0	0 7 6

PENSIONS OF MEDICAL OFFICERS.

Besides the half-pay awarded to medical officers, there are three good-service pensions of 10s. each per diem awarded to the three inspectors-general who have completed the longest and most meritorious services.

There is also one Greenwich Hospital pension of £80 per annum awarded to a deputy inspector-general.

There are fourteen other Greenwich Hospital pensions of £50 each per annum, awarded to those fourteen deputy inspectors-general, staff-surgeons, and surgeons who are considered by the Admiralty to be most deserving of them.

PROMOTIONS.

An assistant-surgeon having served three years may be examined as to his qualifications for promotion to the rank of surgeon. If he be serving abroad he may, if he wish it, be examined provisionally by an inspector or deputy inspector-general and three surgeons ; and as soon after his arrival in England as may be convenient for him to present himself at Somerset House, for his regular and final examination. To enable assistant-surgeons to pass this examination satisfactorily they are granted, on application, two months' leave of absence to prepare themselves for it. The use of passing the provisional examination abroad is, that the assitant-surgeon, having served five years, is then eligible for promotion into any vacancy that may occur, as acting surgeon.

If the vacancy occurring shall have been caused by the death of an officer of superior rank, this promotion as acting-surgeon will be confirmed as surgeon on passing the regular examination at Somerset House. If the vacancy has occurred from any other cause than that of death, the assistant-surgeon appointed to fill it, whether he may have passed only provisionally or finally, will be appointed only as acting-surgeon until the pleasure of the Admiralty be known, who may either confirm him in it, or supersede him by the appointment of a surgeon from half-pay.

Surgeons are promoted to the rank of staff-surgeons on twenty years' service, provided that ten years have been completed since passing for the rank of surgeon.

By an Admiralty regulation dated the 12th of July, 1867, promotion to staff-surgeon is to be open to officers for distinguished or special services, although they may not have completed twenty-years' service.

An officer may be promoted to the rank of inspector-general on the completion of thirteen years' service from the date of his entry into the Royal Navy.

PRIZE-MONEY.

Medical officers share in the proceeds of all prizes captured from the enemy, of captures and seizures under the several Acts of Parliament passed relating to the revenues of customs, and to trade and navigation, for the abolition of the slave trade, for the capture and destruction of pirates and piratical vessels; and of the rewards conferred for the same; as also in the awards of all salvage granted to the crews of Her Majesty's ships and vessels of war, with other officers of corresponding ranks.

POOR-LAW MEDICAL SERVICE.

A YOUNG qualified practitioner, indisposed to be an assistant, and desirous of commencing general practice without investing any money in purchasing a succession, may, perhaps, obtain a Poor-law appointment, though he should scarcely expect to obtain a livelihood from this inadequately remunerated employment.

ENGLISH POOR-LAW MEDICAL SERVICE.

Prior to the passing of the Metropolitan Poor Act of 1867, the English Poor-law Medical Service may be said to have been in the hands of the Guardians, supervised by the Poor-law Board. Each parish in England and Wales had its guardians of the poor, and these parishes were grouped together to form unions. The unions were divided into districts for medical relief. Union medical officers, therefore, have the care of a district, or sometimes the care of the workhouse of the union—sometimes of both. The officer was elected by the guardians, and the appointment approved by the Board. He was required to have both a medical and a surgical qualification. In some instances these were specified, but almost always the London College of Surgeons and Apothecaries' Hall were the two most favoured diplomas. For this reason London students will still continue to take these qualifications, whatever else they may add to them. But the L.R.C.P. Lond. is now recognised as a full qualification, both medical and surgical. These appointments are not lucrative. In most cases the salary is very low. They are, however, sought after by young men as a means of getting into practice, and are often almost obligatory in the country to prevent fresh opposition being introduced. The Metropolitan Poor-law Act, 1867, assimilates the Poor-law, so far as London is concerned, to that of Ireland, and it will probably shortly be extended to the country. It establishes in London asylums and dispensaries, and distributes the cost of supporting them over the metropolis. Unfortunately, the Act has not even yet come into full operation. The appointment of the medical officer will be made by the Dispensary Committee, but the Poor-law Board has power to modify many of the arrangements. The Poor-law Board is now a permanent body with increased powers, but since the Act so few improvements have been effected that the medical officers are very dissatisfied. A Superannuation Act, similar to that of Ireland, has been passed.

THE IRISH POOR-LAW SERVICE.

THE newly-qualified Medical Practitioner, who may elect to try his luck in the Irish provinces, sets his hopes, in the great majority of instances, upon obtaining one or more Poor-law Medical appointments in some district where there is hope of private practice. There are 163 workhouses and 793 Dispensary Medical Officers, besides apothecaries. The number of vacancies that occur annually average 100. The average salary in this service is £90 ; and when it is taken into consideration that, in the vast majority of rural districts, it is necessary to keep a horse, and in some a boat as well, the average area being from forty to sixty square miles, it is plain that there will not be a very large margin left from the public

emoluments. The Medical Officer will also have the refusal of the Registrarship of Births, Marriages, and Deaths, which office in country districts seldom yields more than £10 a year, and often not half that amount. Despite the miserable salary and the very many discomforts of a dispensary life, these appointments are generally eagerly sought for—firstly, because they afford the new comer a certain though hardly-earned salary to supplement his private earnings; and, secondly, because, if not secured by the new comer, they would of necessity bring a competitor for practice into the field, and inasmuch as private income is of far greater import than public earnings, country Medical practitioners are obliged to undertake the public duty in order to save to themselves the monopoly of their private emoluments.

APPOINTMENT.

The qualifications required by the Poor-law Commissioners are a licence in Surgery or a diploma in Medicine, and a diploma in Midwifery; the candidate must also be twenty-three years of age.

The appointment lies with the Dispensary Committee, who elect by vote. As politics and religious feeling run high in Ireland, these elements enter into the election of Poor-law Medical Officers. Family interest also possesses great weight.

The candidate will do well to bear these facts in mind, as his personal attendance on the day of election will be required. And whatever other qualification he may have, he will then find that his compatibility in these respects with the majority of the committee is essential. And, accordingly, he had better first make himself acquainted with the local peculiarity, whatever it may be, before he enters on his candidature, otherwise, in all probability, any expenditure that he may make in the matter will be simply thrown away. We may here observe, also, that in very many instances the appointment is virtually made before the advertisement appears for a Medical Officer, in which case also candidates are put to unnecessary trouble and expense under false pretences.

CONTROL.

Each district is under the direct control of a committee composed of the neighbouring landholders, the appointment of medical and other officers are made by this committee, and the entire management of the district is under their control. Their acts are, however, subject to the approval of the Poor-law Commissioners, who have the power either of interposing their veto on any appointment, or even of expelling an officer by a "sealed order," without trial or accusation, and without the resource of appeal or investigation. This salary is paid by the Board of Guardians, and no increase or decrease can be made in the amount without their assent and that of the Commissioners. Under the late Sanitary Act the committee may recompense the Medical Officer for special services, such as those during an epidemic of cholera, or for sanitary reports. The number of unions in Ireland is 163, to each of which is attached a Medical Officer, who is appointed and controlled by the Board of Guardians in the same manner as the Dispensary Surgeon is by his committee. The salary is usually better than that of the Dispensary Doctor, and the duties of a more easy and satisfactory description, inasmuch as the duty is confined to daily attendance at the Workhouse Hospital, and no night visits out of doors or any long journeys across the country are involved.

DUTIES.

The duty of the Dispensary Doctor is twofold. He is to attend his Dispensary on a given day or days in the week. Frequently there are two dispensaries in the district, separated from each other by several miles, and he will have, perhaps, to attend two days at each. He has also to visit at any hour of the day or night a sick person, for whose relief a visiting ticket has been issued by a member of the committee or by the relieving officer, and to continue his attendance as often as may be necessary until a termination of the case. Moreover, he has a great many registry books to keep, and a multitude of returns to make, and in the majority of districts he has to make up all the medicines for the poor.

The pressure of these duties is in the greatest duty dependent on the goodwill of the members of his committee. If the medical man be a favourite with his masters they will give him very little trouble with "scarlet runners," as the visiting tickets are humorously called, and will be unwilling to trouble him even with cases deserving of personal attendance.

If, on the other hand, it is his misfortune to come in contact with some of the half-bred committee-men, who know nothing of the treatment fit for an educated gentleman, or cherish a personal spite, the discharge of his duties may become simply unbearable. He may be peremptorily summoned, in any weather, at any hour, and to any distance, to a case which he may probably find to be altogether trivial, or to a person whom he may know to be perfectly well, able to pay—Aye! even the committeeman's own brother or daughter. The law unfortunately leaves the Poor-law Medical Officer no protection, and no alternative is open to him but to resign or endure insults and annoyances of the most galling description.

By a recent Act of Parliament Poor-law Medical Officers may now now receive a pension of *one-sixtieth of their salary for each year of service* on being incapacitated from illness or old age. This grant is strictly at the discretion of the guardians, nevertheless it has been given in about eighteen cases in the course of the first year of the operation of the Act.

THE MEDICAL ASSISTANT.

ALMOST every provincial general medical practitioner in England has his qualified or unqualified assistant, and the probationary service of the private practitioner himself is thus very frequently in this capacity. As may be presumed, the duties of the office are very various, and the relations between principal and assistant very complex, so much so as to demand a special volume for themselves, which, from the experienced pen of Mr. Langley, has, under the title of *Via Medica*, passed through several editions.

NOTICES TO CORRESPONDENTS.

Those Gentlemen who have so kindly forwarded us information and corrections, will please receive our best thanks.

RE-OPENING OF THE ARMY MEDICAL DEPARTMENT.—We learn on authority on which we have reliance, that the Competitive Examinations for Assistant-Surgeoncies in the Army, which have ceased for nearly two years, will be recommenced in November next. This will open another field for medical students.

A CONSTANT READER.—You will find a full description of the uses of hydrate of chloral in the letter of our Paris Correspondent, that appeared in the MEDICAL PRESS on the 9th of March last. Several original communications respecting chloral have also appeared in our Journal during the last few months. The manufacture is difficult, and for a practitioner impracticable.

APPOINTMENT OF QUEEN'S PHYSICIAN.—Dr. James Salmon, Inspector-General of Hospitals and Fleets, and the Chief of the Medical Department of Haslar Hospital, has been appointed to the vacant office of Physician to Her Majesty.

MR. BALFOUR BROWNE on "Feigned Insanity."—At an early date.

WE have in type—

Dr Waring-Curran on "Ischuria."

Dr. Bleloch on "Correlation of Forces."

Dr. Waring-Curran on "Fracture of the Pelvic Bones—Recovery."

H. M. Jones, M.D., on "Case of Melanotic Disease of Eye—Removal."

J. A. Waldenstrom on "Alteration in the Urine from the Use of Carbolic Acid."

John A. Bolton. M.D., of Leicester, on "Rheumatism and Gout."

Our Special Correspondents' Letters from Paris and other places.

Accepted articles by Drs. Thorowgood, Martin, Bains, and others, will appear as soon as possible.

DR. MOORE.—Your interesting translation has been received, and will be placed in the printer's hands at once.

THE SEWAGE QUESTION.—Our "Special Reports" will be continued in our next issue, and then from week to week.

Marriage.

MAPOTHER—TOBIN,—On September 7, at St. Mary's Cathedral, Halifax, Nova Scotia, by his Grace the Archbishop, Edward Dillon Mapother, M.D., Dublin, to Ellen, youngest daughter of the late John Tobin, Esq., M.P. for the city.

THE NATIONAL SOCIETY FOR AID TO THE SICK AND WOUNDED IN WAR.

President—H.R.H. the Prince of Wales, K.G., &c.

Chairman of Central Committee—Lieutenant-Colonel Loyd-Lindsay, V.C., M.P.

The Central Committee request that Local Committees will remit each Wednesday, to Messrs. Coutts and Co., the amount collected during the preceding week, advertising the names of Subscribers in the local Newspapers, and sending a copy of the same to the Secretary. It is also urgently requested, that they will have all Material of the same sort packed together, a list of contents written on each bale, and an invoice of the same sent to the Secretary every Saturday. The Stores to be retained by Local Committees until orders are given about them.

In future Subscriptions of less than £5 will not be advertised separately.

The Committee cannot receive contributions sent for the wounded of one billigerent army, but will expend everything as impartially as possible.

C. J. BURGESS, Secretary.

2 St. Martin's place, Trafalgar square, 7th September, 1870.

The Professional Calendar;

OR, WEEKLY REGISTER FOR GENTLEMEN REQUIRING ASSISTANTS, AND FOR ASSISTANTS SEEKING APPOINTMENTS.

EACH Announcement of Three Lines—about thirty words—will be charged at the nominal rate of ONE SHILLING *per insertion* (6d. *each additional line*).

As this Calendar *will be for the use of the Readers of this Journal, and from which no pecuniary advantage will accrue to the Proprietor, each Advertisement* MUST *be accompanied by Postage Stamps* (*Penny*) *in pre-payment.*

A University Graduate, M.B., and L.M., of energy and ability, and good experience, desires an Engagement as Assistant with an elderly Practitioner with a view to Partnership.—Address, Dr. C. P., at Dr Waring Curran's, Osman House, Sutton-in-Ashfield, Notts, for a month.

A duly qualified and registered Surgeon Wanted in an extensive manufacturing and Colliery Practice. Must not fear work.—Address, Chirurgeon, Alfreton, Derbyshire, to be called for.

A Gentleman who has served his apprenticeship to an apothecary, Wants a Situation in an English town where there is a Medical School, to dispense and keep books. Salary expected, £30 per annum, with board and residence.—Address, R. T. L., General Post-office, Belfast, Ireland.

Wanted, an unqualified Irish Assistant, to dispense and keep books. One who has attended a Dublin School of Medicine and could prescribe in absence of principal preferred. Terms £40 per annum in-door.—Address, M. D., Newchurch, near Manchester.

Wanted, a Locum Tenens, who must be qualified for the end of September and October.—Medicus, New Radford, Nottingham.

Wanted immediately, an In-door Dispensing Assistant in a Branch Practice in the Country, to visit (on foot), and attend ordinary midwifery occasionally. Situation light. Salary £30 per annum.—Address, stating age, to R. S. Surgeon, Post-office, Epperstone, near Southwell.

Wanted, by an M.B., C.M., registered, of considerable experience, an In- or Out-door appointment. Can ride or drive.—Address, M.D., 51 Preston place, Bradford, York.

Wanted, for a country practice, an experienced, steady, qualified, and active Assistant.—Address, by letter, Medicus, care of J. S. Moon, Esq., 75 Old Broad street, E.C., London.

Wanted, an Assistant, to dispense, and visit occasionally. Salary £40.—Address, T. T., General Apothecaries' Company, Berners street, Dublin.

Assistant Wanted, sine diploma, to visit, dispense, attend Midwifery, and keep books. Welsh indispensable. None need apply who cannot produce testimonials and good references from last employer.—Address, stating age, height, weight, and with carte, to Jas. R. Walker, Surgeon, Corwen, N. Wales.

To Medical Students.—Wanted, during the Winter Session, a Gentleman competent to prescribe and visit one day weekly—mornings, 9 to 1; evenings, 6 to 10.—Address, by letter only, stating terms, with any other information, to S. Durrant, Esq., 116 Green street, Victoria park, N.E.

Dispenser.—Situation Wanted by the Advertiser, as dispenser and book-keeper, in the early part of October. In- or Out-door. Can be well recommended by present employers.—Address, M., care of Messrs. Oldman and Holderness, Surgeons, Huntingdon.

The Medical Press & Circular.

SPECIAL CORRESPONDENCE.

CORRESPONDENCE.

MEDICAL NEWS.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

PROFESSOR HUXLEY, the President, delivered his address on Wednesday evening, 14th inst., at the Philharmonic Hall. This Hall is one of the largest and handsomest in the kingdom, and it was filled to suffocation. About half the audience were ladies. Professor Stokes, the Rajah of Kallipore, Earl of Derby, Sir Roderick Murchison, Professor Williamson, and many other savants too numerous to mention were present. Professor Huxley was received with great applause. He commenced by saying he would not attempt to give a panoramic survey of the world of science, but would endeavour to put before his audience the history of the rise and progress of a single biological doctrine.

THE ORIGIN OF LIFE.—The philosophers of antiquity, interrogated as to the cause of these phenomena, were provided with a ready and plausible answer. It did not enter their minds even to doubt that these low forms of life were generated in the matters in which they made their appearance. Lucretius, who had drunk deeper of the scientific spirit than any poet of ancient or modern times except Goethe, intends to speak as a philosopher, rather than as a poet, when he writes that "with good reason the earth has gotten the name mother, since all things are produced out of the earth. And many living creatues, even now, spring out of the earth, taking form by the rains and heat of the sun." The axiom of ancient science, "that the corruption of one thing is the birth of another," had its popular embodiment in the notion that a seed dies before the young plant springs from it; a belief so widespread and so fixed, that Saint Paul appeals to it in one of the most splendid outbursts of his fervid eloquence :—

"Thou fool, that which thou sowest is not quickened, except it die."

The proposition that life may, and does, proceed from that which has no life, then, was held alike by the philosophers, the poets, and the people, of the most enlightened nations, eighteen hundred years ago; and it remained the accepted doctrine of learned and unlearned Europe through the middle ages down even to the seventeenth century.

It is commonly counted among the many merits of our great countryman, Harvey, that he was the first to declare the opposition of fact to venerable authority in this, as in other matters; but I can discover no justification for this widespread notion. After careful search through the "Exercitations de Generatione," the most that appears clear to me is, that Harvey believed all animals and plants to spring from what he terms a "*primordium vegetale*," a phrase which may nowadays be rendered "a vegetative germ;" and this, he says, is "*oviforme*," or "egg-like;" not, he is careful to add, that it necessarily has the shape of an egg, but because it has the constitution and nature of one. That this "*primordium oviforme*" must needs, in all cases, proceed from a living parent is nowhere expressly maintained by Harvey, though such an opinion may be thought to be implied in one or two passages; while, on the other hand, he does, more than once, use language which is consistent only with a full belief in spontaneous or equivocal generation. In fact, the main concern of Harvey's wonderful little treatise is not with generation, in the physiological sense, at all, but with development; and his great object is the establishment of the doctrine of epigenesis.

The first distinct enunciation of the hypothesis that all living matter has sprung from preexisting living matter came from a contemporary, though a junior, of Harvey, a native of that country, fertile in men great in all departments of human activity, which was to intellectual Europe, in the sixteenth and seventeenth centuries, what Germany is in the nineteenth. It was in Italy, and from Italian teachers, that Harvey received the most important part of his scientific education. And it was a student trained in the same schools, Francesco Redi—a man of the widest knowledge and most versatile abilities, distinguished alike as scholar, poet, physician, and naturalist—who, just two hundred and two years ago, published his "Esperienze intorno alla Generazione degl' Insetti," and gave to the world the idea, the growth of which it is my purpose to trace. Redi's book went through five editions in twenty years; and the extreme simplicity of his experiments, and the clearness of his arguments, gained for his views, and for their consequences, almost universal acceptance.

SPONTANEOUS GENERATION.—Redi did not trouble himself much with speculative considerations, but attacked particular cases of what was supposed to be "spontaneous generation" experimentally. Here are dead animals, or pieces of meat,

says he; I expose them to the air in hot weather, and in a few days they swarm with maggots. You tell me that these are generated in the dead flesh; but if I put similar bodies, while quite fresh, into a jar, and tie some fine gauze over the top of the jar, not a maggot makes its appearance, while the dead substances, nevertheless, putrefy just in the same way as before. It is obvious, therefore, that the maggots are not generated by the corruption of the meat; and that the cause of their formation must be a something which is kept away by gauze. But gauze will not keep away aëriform bodies, or fluids. This something must, therefore, exist in the form of solid particles too big to get through the gauze. Nor is one long left in doubt what these solid particles are; for the blowflies, attracted by the odour of the meat, swarm round the vessel and, urged by a powerful, but, in this case, misleading instinct, lay eggs, out of which maggots are immediately hatched upon the gauze. The conclusion, therefore, is unavoidable; the maggots are not generated by the meat, but the eggs which give rise to them are brought through the air by flies.

These experiments seem almost childishly simple, and one wonders how it was that no one never thought of them before. Simple as they are, however, they are worthy of the most careful study, for every piece of experimental work since done, in regard to this subject, has been shaped upon the model furnished by the Italian philosopher. As the results of his experiments were the same, however varied the nature of the materials he used, it is not wonderful that there arose in Redi's mind a presumption, that in all such cases of the seeming production of life from dead matter, the real explanation was the introduction of living germs from without into that dead matter. And thus the hypothesis that living matter always arises by the agency of pre-existing living matter, took definite shape; and had, henceforward, a right to be considered aud a claim to be refuted, in each particular case, before the production of living matter in any other way could be admitted by careful reasoners. It will be necessary for me to refer to this hypothesis so frequently, that, to save circumlocution, I shall call it the hypothesis of *Biogenesis;* and I shall term the contrary doctrine—that living matter may be produced by not living matter—the hypothesis of *Abiogenesis.*

Professor Huxley then refers to Biogenesis, Revelations of the Microscope, and proceeds to review the lessons of Modern Chemistry as follows:—

The Lessons of Modern Chemistry.—Modern chemistry, the birth of the latter half of the eighteenth century, grew apace, and soon found herself face to face with the great problems which biology had vainly tried to attack without her help. The discovery of oxygen led to the laying of the foundations of a scientific theory of respiration, and to an examination of the marvellous interactions of organic substances with oxygen. The presence of free oxygen appeared to be one of the conditions of the existence of life, and of those singular changes in organic matters which are known as fermentation and putrefaction. The question of the generation of the infusory animalcules thus passed into a new phase. For what might not have happened to the organic matter of the infusions, or to the oxygen of the air, in Spallanzani's experiments? What security was there that the development of life which ought to have taken place had not been checked or prevented by these changes?

The battle had to be fought again. It was needful to repeat the experiments under conditions which would make sure that neither the oxygen of the air, nor the composition of the organic matter, was altered, in such a manner as to interfere with the existence of life.

Schulze and Schwann took up the question from this point of view in 1836 and 1837. The passage of air through red-hot glass tubes, or through strong sulphuric acid, does not alter the proportion of its oxygen, while it must needs arrest, or destroy, any organic matter which may be contained in the air. These experimenters, therefore, contrived arrangements by which the only air which should come into contact with a boiled infusion should be such as had either passed through red-hot tubes, or through strong sulphuric acid. The result which they obtained was that an infusion so treated developed no living things, while if the same infusion was afterwards exposed to the air such things appeared rapidly and abundantly. The accuracy of these experiments has been alternately denied and affirmed. Supposing them to be accepted, however, all that they really proved was, that the treatment to which the air was subjected destroyed *something* that was essential to the development of life in the infusion. This "something" might be gaseous, fluid, or solid; that it consisted of germs remained only an hypothesis of greater or less probability.

After touching upon the subject of fermentation and putrefaction, and life germs in the air, he epitomises the arguments as follows:—

The Arguments Epitomised.—To sum up the effect of this long chain of evidence:—

It is demonstrable that a fluid eminently fit for the development of the lowest forms of life, but which contains neither germs nor any protein compound, gives rise to living things in great abundance, if it is exposed to ordinary air; while no such development takes place if the air with which it is in contact is mechanically freed from the solid particles which ordinarily float in it, and which may be made visible by appropriate means.

It is demonstrable, that the great majority of these particles are destructible by heat, and that some of them are germs, or living particles, capable of giving rise to the same forms of life as those which appear when the fluid is exposed to unpurified air.

It is demonstrable, that inoculation of the experimental fluid, with a drop of liquid known to contain living particles, gives rise to the same phenomena as exposure to unpurified air.

And it is further certain that these living particles are so minute that the assumption of their suspension in ordinary air presents not the slightest difficulty. On the contrary, considering their lightness, and the wide diffusion of the organisms which produce them, it is impossible to conceive that they should not be suspended in the atmosphere in myriads.

Thus, the evidence, direct and indirect, in favour of *Biogenesis* for all known forms of life must, I think, be admitted to be of great weight.

On the other side, the sole assertions worthy of attention are, that hermetically sealed fluids, which have been exposed to great and long-continued heat, have sometimes exhibited living forms of low organisation when they have been opened.

The first reply that suggests itself is the probability that there must be some error about these experiments, because they are performed on an enormous scale every day with quite contrary results. Meat, fruit, vegetables, the very materials of the most fermentable and putrescible infusions are preserved to the extent, I suppose I may say, of thousands of tons every year, by a method which is a mere application of Spallanzani's experiment. The matters to be preserved are well boiled in a tin case provided with a small hole, and this hole is soldered up when all the air in the case has been replaced by steam. By this method they may be kept for years without putrefying, fermenting, or getting mouldy. Now this is not because oxygen is excluded, inasmuch as it is now proved that free oxygen is not necessary for either fermentation or putrefaction. It is not because the tins are exhausted of air, for *Vibriones* and *Bacteria* live, as Pasteur has shown, without air or free oxygen. It is not because the boiled meats or vegetables are not putrescible or fermentable, as those who have had the misfortune to be in a ship supplied with unskilfully closed tins well know. What is it, therefore, but the exclusion of germs? I think that Abiogenists are bound to answer this question before they ask us to consider new experiments of precisely the same order.

And, in the next place, if the results of the experiments I refer to are really trustworthy, it by no mean follows that Abiogenesis has taken place. The resistance of living matter to heat is known to vary within considerable limits, and to depend, to some extent, upon the chemical and physical qualities of the surrounding medium. But if, in the present state of science, the alternative is offered us, either germs can stand a greater heat than has been supposed, or the molecules of dead matter, for no valid or intelligible reason that is assigned, are able to re-arrange themselves into living bodies, exactly such as can be demonstrated to be frequently produced in another way, I cannot understand how choice can be, even for a moment, doubtful.

The Origin of Life.—But though I cannot express this conviction of mine too strongly, I must carefully guard myself against the supposition that I intend to suggest that no such thing as Abiogenesis ever has taken place in the past, or ever will take place in the future. With organic chemistry, molecular physics, and physiology yet in their infancy, and every day

making prodigious strides, I think it would be the height of presumption for any man to say that the conditions under which matter assumes the properties we call "vital" may not, some day, be artificially brought together. All I feel justified in affirming is, that I see no reason for believing that the feat has been performed yet.

And, looking back through the prodigious vista of the past, I find no record of the commencement of life, and therefore I am devoid of any means of forming a definite conclusion as to the conditions of its appearance. Belief, in the scientific sense of the word, is a serious matter, and needs strong foundations. To say, therefore, in the admitted absence of evidence, that I have any belief as to the mode in which the existing forms of life have originated, would be using words in a wrong sense. But expectation is permissible where belief is not; and if it were given me to look beyond the abyss of geologically-recorded time to the still more remote period when the earth was passing through physical and chemical conditions, which it can no more see again than a man can recall his infancy, I should expect to be a witness of the evolution of living protoplasm from not living matter. I should expect to see it appear under forms of great simplicity, endowed like existing Fungi, with the power of determining the formation of new protoplasm from such matters as ammonium carbonates, oxalates, and tartrates, alkaline and earthy phosphates, and water, without the aid of light. That is the expectation to which analogical reasoning leads me; but I beg you once more to recollect that I have no right to call my opinion anything but an act of philosophical faith.

So much for the history of the progress of Redi's great doctrine of Biogenesis, which appears to me, with the limitations I have expressed, to be victorious along the whole line at the present day.

Development of Species.—As regards the second problem offered to us by Redi, whether Xenogenesis obtains side by side with Homogenesis, whether, that is, there exist not only the ordinary living things, giving rise to offspring which run through the same cycle as themselves, but also others, producing offspring which are of a totally different character from themselves,—the researches of two centuries have led to a different result. That the grubs found in galls are no product of the plants on which the galls grow, but are the result of the introduction of the eggs of insects into the substance of these plants, was made out by Vallisnieri, Reaumur, and others, before the end of the first half of the eighteenth century. The tapeworms, bladderworms, and flukes continued to be a stronghold of the advocates of Xenogenesis for a much longer period. Indeed, it is only within the last thirty years that the splendid patience of Von Siebold, Van Beneden, Leuckart, Küchenmeister, and other helminthologists, has succeeded in tracing every such parasite, often through the strangest wanderings and metamorphoses, to an egg derived from a parent, actually or potentially like itself; and the tendency of inquiries elsewhere has all been in the same direction. A plant may throw off bulbs, but these, sooner or later, give rise to seeds or spores, which develope into the original form. A polype may give rise to Medusæ, or a pluteus to an Echinoderm; but the Medusæ and the Echinoderm give rise to eggs which produce polypes or plutei, and they are therefore only stages in the cycle of life of the species.

But if we turn to pathology it offers us some remarkable approximations to true Xenogenesis.

As I have already mentioned, it has been known since the time of Vallisnieri and of Reaumur that galls in plants and tumours in cattle are caused by insects, which lay their eggs in those parts of the animal or vegetable frame of which these morbid structures are outgrowths. Again, it is a matter of familiar experience to everybody that mere pressure on the skin will give rise to a corn. Now, the gall, the tumour, and the corn are parts of the living body, which have become, to a certain degree, independent and distinct organisms. Under the influence of certain external conditions, elements of the body, which should have developed in due subordination to its general plan, set up for themselves, and apply the nourishment which they receive to their own purposes.

From such innocent productions as corns and warts there are all gradations, to the serious tumours which, by their mere size and the mechanical obstruction they cause, destroy the organism out of which they are developed; while, finally, in those terrible structures known as cancers, the abnormal growth has acquired powers of reproduction and multiplication, and is only morphologically distinguishable from the parasitic worm, the life of which is, neither more nor less, closely bound up with that of the infested organism.

If there were a kind of diseased structure the histological elements of which were capable of maintaining a separate and independent existence out of the body, it seems to me that the shadowy boundary between morbid growth and Xenogenesis would be effaced. And I am inclined to think that the progress of discovery has almost brought us to this point already. I have been favoured by Mr. Simon with an early copy of the last published of the valuable "Reports on the Public Health," which, in his capacity of their medical officer, he annually presents to the Lords of the Privy Council. The appendix to this report contains an introductory essay "On the Intimate Pathology of Contagion," by Dr. Burdon Sanderson, which is one of the clearest, most comprehensive, and well-reasoned discussions of a great question which has come under my notice for a long time. I refer you to it for details and for the authorities for the statements I am about to make.

Vaccination.—You are familiar with what happens in vaccination. A minute cut is made in the skin, and an infinitesimal quantity of vaccine matter is inserted into the wound. Within a certain time a vesicle appears in the place of the wound, and the fluid which distends this vesicle is vaccine matter, in quantity a hundred or a thousandfold that which was originally inserted. Now what has taken place in the course of this operation? Has the vaccine matter by its irritative property produced a mere blister, the fluid of which has the same irritative property? Or does the vaccine matter contain living particles, which have grown and multiplied where they have been planted? The observations of M. Chauveau, extended and confirmed by Dr. Sanderson himself, appear to leave no doubt upon this head. Experiments, similar in principle to those of Helmholtz on fermentation and putrefaction, have proved that the active element in the vaccine lymph is non-diffusible, and consists of minute particles not exceeding 1-20,000th of an inch in diameter, which are made visible in the lymph by the microscope. Similar experiments have proved that two of the most destructive of epizootic diseases, sheep-pox and glanders, are also dependent for their existence and their propagation upon extremely small living solid particles, to which the title of *microzymes* is applied. An animal suffering under either of these terrible diseases is a source of infection and contagion to others, for precisely the same reason as a tub of fermenting beer is capable of propagating its fermentation by "infection" or "contagion," to fresh wort. In both cases it is the solid living particles which are efficient; the liquid in which they float, and at the expense of which they live, being altogether passive.

Now arises the question, are these microzymes the results of *Homogenesis*, or of *Xenogenesis;* are they capable, like the *Torulæ* of yeast, of arising only by the development of pre-existing germs; or may they be, like the constituents of a nut-gall, the results of a modification and individualization of the tissues of the body in which they are found, resulting from the operation of certain conditions? Are they parasites in the zoological sense, or are they merely what Virchow has called "heterologous growths?" It is obvious that this question has the most profound importance, whether we look at it from a practical or from a theoretical point of view. A parasite may be stamped out by destroying its germs, but a pathological product can only be annihilated by removing the conditions which give rise to it.

It appears to me that this great problem will have to be solved for each zymotic disease separately, for analogy cuts two ways. I have dwelt upon the analogy of pathological modification, which is in favour of the xenogenetic origin of microzymes; but I must now speak of the equally strong analogies in favour of the origin of such pestiferous particles by the ordinary process of the generation of like from like.

It is, at present, a well-established fact that certain diseases, both of plants and of animals, which have all the characters of contagious and infectious epidemics, are caused by minute organisms. The smut of wheat is a well-known instance of such a disease, and it cannot be doubted that the grape disease and the potato disease fall under the same category. Among animals, insects are wonderfully liable to the ravages of contagious and infectious diseases caused by microscopic *Fungi*.

Fly Plagues.—In autumn it is not uncommon to see flies motionless upon a window-pane, with a sort of magic circle, in white, drawn round them. On microscopic examination the

magic circle is found to consist of innumerable spores, which have been thrown off in all directions by a minute fungus called *Empusa muscæ*, the spore-forming filaments of which stand out like a pile of velvet from the body of the fly. These spore-forming filaments are connected with others, which fill the interior of the fly's body like so much fine wool, having eaten away and destroyed the creature's viscera. This is the full-grown condition of the *Empusa*. If traced back to its earlier stages, in flies which are still active, and to all appearance healthy, it is found to exist in the form of minute corpuscles which float in the blood of the fly. These multiply and lengthen into filaments, at the expense of the fly's substance; and when they have at last killed the patient, they grow out of its body and give off spores. Healthy flies shut up with diseased ones catch this mortal disease and perish like the others. A most competent observer, M. Cohn, who studied the development of the *Empusa* in the fly very carefully, was utterly unable to discover in what manner the smallest germs of the *Empusa* got into the fly. The spores could not be made to give rise to such germs by cultivation; nor were such germs discoverable in the air, or in the food of the fly. It looked exceedingly like a case of Abiogenesis, or, at any rate, of Xenogenesis; and it is only quite recently that the real course of events has been made out. It has been ascertained that when one of the spores falls upon the body of a fly it begins to germinate and sends out a process which bores its way through the fly's skin; this, having reached the interior cavities of its body, gives off the minute floating corpuscles which are the earliest stage of the *Empusa*. The disease is "contagious," because a healthy fly coming in contact with a diseased one, from which the spore-bearing filaments protrude, is pretty sure to carry off a spore or two. It is "infectious," because the spores become scattered about all sorts of matter in the neighbourhood of the slain flies.

Diseases of the Silkworm.—The silkworm has long been known to be subject to a very fatal contagious and infectious disease called the *Muscardine*. Audouin transmitted it by inoculation. This disease is entirely due to the development of a fungus, *Botrytis Bassiana*, in the body of the caterpillar; and its contagiousness and infectiousness are accounted for in the same way as those of the fly-disease. But of late years a still more serious epizootic has appeared among the silkworms; and I may mention a few facts which will give you some conception of the gravity of the injury which it has inflicted on France alone.

The production of silk has been, for centuries, an important branch of industry in Southern France, and in the year 1853 it had attained such a magnitude that the annual produce of the French sericulture was estimated to amount to a tenth of that of the whole world, and represented a money value of 117,000,000 of francs, or nearly five millions sterling. What may be the sum which would represent the money value of all the industries connected with the working-up of the raw silk thus produced is more than I can pretend to estimate. Suffice it to say, that the city of Lyons is built upon French silk, as much as Manchester was upon American cotton before the civil war.

Silkworms are liable to many diseases; and, even before 1853, a peculiar epizootic, frequently accompanied by the appearance of dark spots upon the skin (whence the name of "Pebrine" which it has received), had been noted for its mortality. But in the years following 1853 this malady broke out with such extreme violence that in 1856 the silk crop was reduced to a third of the amount which it had reached in 1853; and, up till within the last year or two, it has never attained half the yield of 1853. This means not only that the great number of people engaged in silk-growing are some thirty millions sterling poorer than they might have been; it means not only that high prices have had to be paid for imported silkworm eggs, and that, after investing his money in them, in paying for mulberry-leaves and for attendance, the cultivator has constantly seen his silkworms perish and himself plunged in ruin—but it means that the looms of Lyons have lacked employment, and that, for years, enforced idleness and misery have been the portion of a vast population which, in former days, was industrious and well to do.

In 1858 the gravity of the situation caused the French Academy of Sciences to appoint commissioners, of whom a distinguished naturalist, M. de Quatrefages, was one, to inquire into the nature of this disease, and, if possible, to devise some means of staying the plague. In reading the report made by M. de Quatrefages, in 1859, it is exceedingly interesting to observe that his elaborate study of the Pébrine forced the conviction upon his mind that, in its mode of occurrence and propagation, the disease of the silkworm is, in every respect, comparable to the cholera among mankind. But it differs from the cholera, and, so far, is a more formidable disease, in being hereditary, and in being, under some circumstances, contagious, as well as infectious.

The Italian naturalist, Filippi, discovered in the blood of the silkworms affected by this strange disease a multitude of cylindrical corpuscles, each about 1-6000 of an inch long. These have been carefully studied by Lebert, and named by him *Panhistophyton*; for the reason that, in subjects in which the disease is strongly developed, the corpuscles swarm in every tissue and organ of the body, and even pass into the undeveloped eggs of the female moth. But are these corpuscles causes, or mere concomitants, of the disease? Some naturalists took one view and some another; and it was not until the French Government alarmed by the continued ravages of the malady, and the inefficiency of the remedies which had been suggested, dispatched M. Pasteur to study it, that the question received its final settlement; at a great sacrifice, not only of the time and peace of mind of that eminent philosopher but, I regret, to have to add, of his health.

But the sacrifice has not been in vain. It is now certain that this devastating, cholera-like, Pebrine is the effect of the growth and multiplication of the *Panhistophyton* in the silkworm. It is contagious and infectious because the corpuscles of the *Panhistophyton* pass away from the bodies of the diseased caterpillars, directly or indirectly, to the alimentary canal of healthy silkworms in their neighbourhood; it is hereditary, because the corpuscles enter into the eggs while they are being formed, and consequently are carried within them when they are laid; and for this reason, also, it presents the very singular peculiarity of being inherited only on the mother's side. There is not a single one of all the apparently capricious and unaccountable phenomena presented by the Pébrine but has received its explanation from the fact that the disease is the result of the presence of microscopic organism, *Panhistophyton*.

Such being the facts with respect to the Pébrine, what are the indications as to the method of preventing it? It is obvious that this depends upon the way in which the *Panhistophyton* is generated. If it may be generated by Abiogenesis, or by Zenogenesis, within the silkworm or its moth, the extirpation of the disease must depend upon the prevention of the occurrence of the conditions under which this generation takes place. But if, on the other hand, the *Panhistophyton* is an independent organism, which is no more generated by the silkworm than the misletoe is generated by the oak, or the apple-tree, on which it grows, though it may need the silkworm for its development in the same way as the misletoe needs the tree, then the indications are totally different. The sole thing to be done is to get rid of, and keep away the germs of the *Panistophyton*. As might be imagined, from the course of his previous investigations, M. Pasteur was led to believe that the latter was the right theory; and guided by that theory, he has devised a method of extirpating the disease, which has proved to be completely successful wherever it has been properly carried out.

There can be no reason, then, for doubting that, among insects, contagious and infectious diseases, of great malignity, are caused by minute organisms which are produced from pre-existing germs, or by Homogenesis; and there is no reason, that I know of, for believing that what happens in insects may not take place in the highest animals. Indeed, there is already strong evidence that some diseases of an extremely malignant and fatal character to which man is subject, are as much the work of minute organisms as is the Pébrine. I refer for this evidence to the very striking facts adduced by Professor Lister in his various well-known publications on the antiseptic method of treatment. It seems to me impossible to rise from the perusal of those publications without a strong conviction that the lamentable mortality which so frequently dogs the footsteps of the most skilful operator, and those deadly consequences of wounds and injuries which seem to haunt the very walls of great hospitals, and are, even now, destroying more men than die of bullet, or bayonet, are due to the importation of minute organisms into wounds, and their increase and multiplication; and that the surgeon who saves most lives will be he who best works out the practical consequences of the hypothesis of Redi.

Conclusions.—I commenced this address by asking you to follow me in an attempt to trace the path which has been

followed by a scientific idea, in its long and slow progress from the position of a probable hypothesis to that of an established law of nature. Our survey has not taken us into very attractive regions; it has lain, chiefly, in a land flowing with the abominable, and peopled with mere grubs and mouldiness. And it may be imagined with what smiles and shrugs practical and serious contemporaries of Redi and of Spallanzani may have commented on the waste of their high abilities in toiling at the solution of problems which, though curious enough in themselves, could be of no conceivable utility to mankind.

Nevertheless, you will have observed that before we had travelled very far upon our road there appeared on the right hand and on the left fields laden with a harvest of golden grain, immediately convertible into those things which the most sordidly practical of men will admit to have value—namely, money and life.

The direct loss to France caused by the Pébrine in seventeen years cannot be estimated at less than fifty million sterling; and if we add to this what Redi's idea, in Pasteur's hands, has done for the wine-grower and for the vinegar maker, and try to capitalise its value, we shall find that it will go a long way towards repairing the money losses caused by the frightful and calamitous war of this autumn.

And as to the equivalent of Redi's thought in life, how can we over-estimate the value of that knowledge of the nature of epidemic and epizootic diseases, and consequently of the means of checking or eradicating them, the dawn of which has assuredly commenced.

Looking back no further than ten years, it is possible to select three (1863, 1864, and 1869) in which the total number of deaths from scarlet fever alone amounted to ninety thousand. That is the return of killed, the maimed and disabled being left out of sight. Why, it is to be hoped that the list of killed in the present bloodiest or all wars will not amount to more than this! But the facts which I have placed before you must leave the least sanguine without a doubt that the nature and the causes of this scourge will, one day, be as well understood as those of the Pébrine are now; and that the long suffered massacre of our innocents will come to an end.

And thus mankind will have one more admonition that "the people perish for lack of knowledge;" and that the alleviation of the miseries and the promotion of the welfare of men must be sought by those who will not lose their pains in that diligent, patient, loving study of all the multitudinous aspects of nature, the results of which constitute exact knowledge or science.

It is the justification and the glory of this great meeting that it is gathered together for no other object than the advancement of the moiety of science which deals with those phenomena of nature which we call physical. May its endeavours be crowned with a full measure of success!

BRITISH PHARMACEUTICAL CONFERENCE, 1870.

The President of this, the seventh meeting, was Mr. J. Stoddart, F.C.S., of Bristol.

His Inaugural Address was delivered at the Royal Institution, Liverpool, and recalled some of the most prominent observations and discoveries of the previous year.

The fundamental idea of the Conference was the furtherance of pharmacy proper, by directing attention to the proper means of scientific education or judicious training, and the advancement of the pharmaceutists' status as a profession. He could not endorse Adam Smith's observation, that a philosopher was a person "whose trade is to do nothing and speculate in everything." Where would be our telegraph if Faraday and Œrstadt had not studied the properties of an electrified wire; or the wonderful calculations of astronomy if Newton had let the fall of an apple pass by unheeded? To the student nothing was too trifling or unimportant. We lived in complete subjection to Nature's laws, and how foolish not to learn what those laws required, so that we might have them with us and not against us! Pharmacy, of all pursuits, was the one most dependent on the proper use of these laws, and the pharmaceutist must make the most he could of the animal, vegetable, and mineral substances with which he had to do, with the view of producing the best results. The Pharmacy Act obtained two years ago had worked well, but its expected benefits were more decidedly in the future. Let them, however, beware of infusing a mercenary spirit into the conduct of their society. Its main object ever must be the upraising of their pharmaceutical education, and not the lowering it into a trades union, a spirit which would prove its ruin. Chemistry, botany, and physics were to them only secondary in importance to a well-grounded general education, and the study of botany was peculiarly a necessity.

After describing most of the important discoveries of the year in chemistry, he went on to say:—

The vegetable alkaloids, it was true, had not yet been artificially produced, but so great an advance was being made in the formation of organic compounds by artificial means, that it was too chimerical an idea to expect a pharmaceutical solution of the philosopher's stone problem, and to manufacture quinia and morphia on a large scale, so as to be entirely independent of the cinchonaceæ and puparaceæ, on which we now entirely rely for these invaluable medicines. The President illustrated the advantage of a knowledge of natural physics, because many of the most beautiful phenomena pass under the dispenser's eye every day. By means of the spectroscope many elements had been detected in articles of the materia medica which, a few years ago, were considered great rarities. On the table he exhibited the ashes of many pharmacopœial substances containing the metals rubidium, lithium, and strontium. In a case of cattle poisoning at Wells assizes the animals were proved to have been killed by eating plants containing lead derived from the soil on which they grew. Analysis showed that the grass, weeds, fungi, thistles, and shrubs contained a ponderous quantity of lead, although totally unaffected in their growth. The past year had been prolific in so many new and important discoveries that it became difficult to point out one or two only for consideration. At the last meeting chloral-hydrate was an expensive curiosity; now it was manufactured in enormous quantities, and he regretted that already another preparation had been introduced, containing only 70 instead of 90 per cent. of chloral, and was declared by Dr. Liebreicht to be devoid of therapeutic power. Sulpho-carbolic acid was another preparation that had recently been brought into use. It was made by combining sulphuric and carbolic acids in their molecular weights (49 to 94), at a temperature of 290 Fahr. Many physicians affirmed that it was a more powerful disinfectant than plain carbolic acid. The madder plant was employed as a medicinal agent in the manufacturing districts, principally for tincturial purposes, and £1,000,000 was annually paid by us for foreign madder. Two Germans had recently succeeded in artificially making aligarine, the colouring matter of madder. Since the Exeter meeting, an international congress of pharmacentists had been held at Vienna. He trusted that the opportunity would occur for reciprocating the friendly feeling exercised on that occasion by a cordial invitation to our own shores. In conclusion, he impressed on the Conference the importance of sinking petty differences of opinion, and advancing the promotion of pharmacy. Government showed a disposition to help them in every way, and would give a decided preference to those who passed the examinations. For instance, they would admit no candidate for the office of naval dispenser until he had a satisfactory diploma from the Pharmaceutical Society. In return, the members of the Society were in duty bound to see that they fulfilled their trust, and discharged the moral obligation that they had entrusted to their care. As the general tendency of the medical profession was to leave the dispensing of prescriptions to pharmacists, it was therefore their duty to lose no time in rendering themselves competent to undertake the office in the best manner.

The address was much applauded, and on the motion of Mr. Mackie (Edinburgh), seconded by Mr. Williams (London), thanks were voted to the President for his very able address.

The report of the Executive Committee stated that during the year they had been engaged in organising the production of such a year-book for 1870 as the Exeter Conference decided should be issued; in the completion of a system of canvassing for members among the pharmacentists of England, with the object of advancing the general aims of the Conference, and securing sufficient for the uninterrupted production of a year-book; and in the appropriate disposal of the Bell and Hills' Library Fund, a sum of 50 guineas, generously given by Mr. Thos. Hyde Hills for stimulating pharmaceutical education. The services of Mr. John Cargill Brough had been obtained

as editor of the year-book, and the volume was to be issued not later than December 1st. The number of members had been increased from 600 to about 1,500, and a still further increase was anticipated upon the distribution of the year-book and a recognition of its value. The scheme connected with the Bell and Hills' Library Fund is the presentation of ten guineas' worth of books to the pharmaceutical chymists—the chymists and druggists of the cities and towns in which the Conference meets—as an addition to, or the nucleus for, the formation of a library where assistants or apprentices may study and improve themselves; and this had already been done at Exeter.

On the two following days communications were read by Dr. Attfield "On Bitter Cassava Juice, and its supposed Antiseptic Properties," Mr. Rimmington "On Citrate of Magnesia," Mr. J. Watts, B.Sc., "On the Chemical Constitution of Sulphurated Potash," Mr. C. Tichborne, F.C.S., "On Sulphite of Zinc," and others from Messrs. J. Ince, W. Tilden, Morson, &c.

Original Communications.

CORRELATION OF THE PHYSICAL AND VITAL FORCES.

By Archibald Bleloch, A.M., Glasg., D.Sc., M.B. and C.M. Ed.

In physical science, electricity, magnetism, galvanism, mechanical force, heat, light, motion, are various terms expressing the same thing under different conditions, and in varying relations. The terms are convertible because the things signified are all of one nature. Motion is the *ultima reductio*; each is convertible into the other without any residuum. In natural science we have terms of corresponding import, and the things signified are also of one nature. The terms *vis nervosa*, muscular contraction, animal caloric, growth, and nutrition, are expressive of the same thing under different conditions and in varying relations. Each is convertible into the other without any residuum. Motion is the *ultima reductio*.

In physical science we have inorganic substrata necessary to the phenomena of physical force. In natural science we have organic substrata necessary to the phenomena of vital force. The difference resides in the substrata, and not in the forces. The words vital and physical are wholly concerned with the substrata, and hence, when the substrata are changed, vital force passes into physical force and *vice versâ*. The different phases of vital force are allotropic of the different phases of physical force, and the same correlation is observable in both the one and the other. When we speak of *vis nervosa* being eliminated and transmitted, we understand by these terms the origination and propagation of motion in the tissues which make up the nerve centres and nerve tubes. This particular kind of motion is originated in the cells and granules of the nerve centres, and is propagated from particle to particle of the fluid in the nerve tubes until it reaches the muscle, when it is immediately converted into contractile force. The *vis nervosa*, allotropic of electricity or galvanism, passes from the axis cylinder of the nerve tube to the fibrinogen and fibrino-plastic of the muscular structure, and contraction is the result. What takes place here, in natural science is exactly analogous to what happens when the physicist converts electricity or galvanism into mechanical force. The difference in the substrata modifies the quality of the force, but the correlation remains the same. Heat, light, electricity assumed the character of vital forces when they operate in an organized structure fitted to the particular kind of motion which they severally represent; and as heat becomes electricity by passing through a certain combination of metals, so *vis nervosa* becomes animal caloric in certain conditions of organised tissue. A change in the substrata coincides with a conversion of the force into some one or other of its allotropic forms whether that force operates, for the time being, in organised living tissue, or in inorganic matter as such. It is well known that a current of electricity passes into muscular contractile force, without the mediation of *vis nervosa*, when conducted to living muscular structure, and it has also been abundantly proved that electricity is equally productive of muscular contractile force through this mediation, The explanation is simple: electricity, *vis nervosa*, and muscular contractile force are different forms of one and the same thing. The substrata change, and, therefore, the phenomena. The experiment instituted to prove that electricity is not *vis nervosa*, by dividing the nerve tube and substituting a piece of metallic wire, is not scientific. It confounds the organic with the inorganic world. It forgets that while an organism lives, all the physical forces are modified to its acquirements. It is not meant by this that a living organised being is exempt from the operation of the physical forces as such. The physical forces embrace all matter, organic and inorganic in their operations. What is meant is, that the functions of the living being are carried on by allotropic forms of the physical forces, and that these forms are determined by the substrata. Life is the sum of the allotropic forms which the physical forces assume in the substrata of the living organism. Death takes place when these substrata are no longer able to modify the physical forces so as to carry on the functions of life. To prove this we have only to place a seed in circumstances where the physical forces, and the elements essential to growth and nutrition are present. The seed forms the substrata altogether apart from the forces which effect the growth of the tree. A seed does not live until the substrata of which it is composed are subjected to the influence of the physical forces, heat, light, electricity, &c. These enter the substrata and regulate, under allotropic forms, the growth and nutrition of the plant. In fact, they constitute its life, continuing to operate so long as nutrient materials are supplied, and the substrata do not become effete—when this takes place the plant dies. If it be asked whence came the substrata? We reply that the physical forces through their allotropic forms perpetuate the substrata of the different species of plants and animals, but they cannot originate organic substrata, because this would imply that they can assume the characteristics of vital forces in purely inorganic substrata which is impossible. There is, therefore, no need of experiment to determine the question of spontaneous generation. It is an absurdity. It is contrary to the laws of physical science. This, however, does not alter the fact of the correlations of the physical and vital forces. A sound is propagated through unorganised matter by the rapid oscillation of the inorganic molecules, and in the same manner it strikes the tympanum, and thence through the ossicles of the internal ear, until it reaches the wonderful apparatus in which the auditory nerve terminates, when it is immediately converted into *vis nervosa*, and the phenomenon of sound is conveyed to the intelligence. The latter half of the process is effected in the same manner as the former. The one is effected through the oscillation of inorganic particles, the other is effected through the oscillation of organic nerve cells, granules, and the particles of nervous fluid. It is now held that the phenomenon of light is the result of a certain form of motion in what is termed a luminiferous ether pervading space, and which exists between the molecules of transparent bodies. Undulations are propagated through this medium, and, so long as the particles moved are inorganic, they maintain the characteristics of a purely physical force, and as such they pass through the lenses of the eye, but when they reach the retina, their allotropic form light is propagated by that apparatus through the optic nerve to the intelligence. In the case of the sense of touch, we have an instance of simple mechanical force converted into *vis nervosa*. The terminations of the sensory nerves in the dermal surface

are said to receive an impression, but the truth is, that the mechanical impact or force applied to the tactile bodies in which the sensory nerves terminate, passes into a successive oscillation of the particles of fluid in the sensory nerve tubes. The sensation of touch is the consciousness of the oscillation of these particles, carried up to the sensorium. So also with the other senses, taste and smell. They are closely allied to the sense of touch. They have special nerves, but communicate with the intelligence in a similar manner.

When *vis nervosa* passes along the nutrient nerve tubes it assumes the character of an allotropic form of magnetism. It is animal magnetism. It operates in the organized structure and attracts the nutrient materials appropriate to the growth and nutrition of the different parts. Again, when the *vis nervosa* passes along the nerve tubes that supply the various secreting cells, as for instance, those of the kidneys, those of the liver, or those of the intestinal glands, it assumes the form of a vital chemical affinity. It passes into the various elaborations, and in these remains stored up for further service, or for elimination. When the *vis nervosa* in the nerves is deranged through some disease of the nerve centre, the *physio-chemical* result becomes vitiated. We have then diabetes, oxaluria, excess of uric acid, and such like. All this becomes intelligible on the supposition that the physical and vital forces are correlated, and that the one passes into the other when the substrata necessary to their different phenomena are presented.

FRACTURE OF THE PELVIC BONES—RECOVERY.

By J. Waring-Curran, L.K. & Q.C.P., L.R.C.S.I., &c.

Two or three years ago I recorded in the columns of The Press and Circular the particulars of a case of fractured pelvis, which terminated fatally. The paper was copied into the American and Australian medical journals, and attracted some attention at the time. The history of the following case is interesting considering the important nature of the injuries sustained, and the fact of the patient recovering, or making as good a recovery as the nature of the case would, under the most favourable circumstances, permit.

B. B., a collier, aged two-and-thirty years, whilst at work in the pit was severely crushed by the fall of at least five tons of coal upon him. When extricated by his fellow workmen, it was discovered the greater part of the coal had fallen upon the lower part of the body. When I visited him he was in a state of collapse, and, upon removing his garments, discovered that he had passed urine, that the horizontal rami of ischiun and pubis were depressed; and having satisfied myself that there was no fracture or dislocation of the extremities to be reduced, I had him placed in a warm bed, with hot water bottles, and resorted to the other usual means for bringing about reaction. Upon visiting him two hours afterwards, I found him rational. He told me he was in a stooping position when the fall of "bind" and coal took him in the lower part of the back, which pressed out his water. He complained of excruciating pain, deep seated, in the pelvic region. He was unable to lie on his back or side, but was being supported by two men, one on either side, around whose neck he placed his arms and kept the pelvis off the bed. I administered an opiate, and, as it was dark, delayed any further examination until the morning; but, in the course of a few hours, I was hastily summoned, as he required to pass water and was unable to do so. I found urine in the bladder, and tried to introduce a catheter, but failed, as the point of the instrument reached about the base of the triangular ligament, it was met by a firm resistance, in trying to manœuvre my instrument past the obstruction, I conceived that it grated against a piece of jagged bone, but past it the catheter would not go.

Another surgeon, at my request, came to my assistance, and he also failed to pass the instrument. The symptoms were not sufficiently urgent to demand tapping, so that we delayed further interference until the next day, when I was met by, what is called in colliery districts, "The Field Doctor." He also tried to pass the instrument, and without success. Now, urine was evidently infiltrated into the perineum and scrotal tissue. A water cushion was provided, and, curious to say, the man in the evening passed a quantity of bloody urine with a strong ammoniacal odour through the natural channel; he had no control over the stream. We were able to detect crepitus over the horizontal rami of ischiun and pubis, and had no doubt of the existence of a fracture of the descending rami of the left side, the end of either fragment being directed inwards upon the urethra; I tried to pass a catheter, but without success; the obstruction, and that bony, was still readily felt; no doubt a false passage existed. The patient was well sustained, and every little symptom attended to with zeal and assiduous care by "The Field Doctor." In nine weeks he was able to leave his bed; in twelve, he could place the right foot to the ground, but the left he was unable to straighten without excruciating pain. Supplied with crutches, and accommodated with a hollow seated padded chair, with an eminence on either side to support the tuberosities of the ischia, he was got into another room each day. The passage of the water again stopped, when an instrument was passed in through a tortuous urethra as the obstruction still existed.

It is now nine months since the date of the accident; the man is able to walk, but still unfit to follow his usual occupation. There is great weakness of the left side, and occasionally the water has to be drawn off through an instrument. He suffers from spasmodic pains at times, which a warm bath generally relieves, otherwise the man appears well. He thinks in a couple of weeks of resuming his employment, but he is unable to bend the body, or stoop as in the act of lifting an object from the ground.

The case is interesting, considering the very grave nature of the accident, and the result is most satisfactory; whilst it teaches the lesson that we should not be too officious, but wait Nature's efforts. I am free to confess, we might have forced a passage at once, or tapped the bladder, were it not from the existence of different fractures that we considered the case hopeless, and that it would only be unnecessary cruelty punishing the patient more.

THE SEWAGE QUESTION.

SPECIAL REPORT.

(Prepared expressly for the Medical Press.)

No. IV.

RUGBY SEWAGE FARM.

The population of Rugby is about 9,000, and the sewage amounts to from 220,000 to 250,000 gallons a day. It flows by gravitation partly to the old works, which distribute the sewage to the low level fields, and partly to the new works, at a higher level. At both places, however, the operations are the same—the sewage being strained through perforated boards, with holes about one and quarter inch diameter, and six inches apart; and then it flows by open carriers over the ground.

At the low level works the sewage (amounting to about one-third of the whole supply) is distributed over about sixteen acres of land, of the nature of a loose gravelly clay, upon a subsoil of clay which rests upon stone.

The high level sewage (amounting to two-thirds of the supply) is distributed upon forty-nine acres of land, of the

same nature of soil, and which is entirely laid out with Italian rye grass.

The farm is about a mile west of Rugby, and at the time of our visit it was, in places, quite saturated with sewage, and had an offensive odour, and it was not until it had flowed successively over three or four portions of land that it was sufficiently purified to be admissible into a running stream.

We took samples of sewage at its entrance upon the farm, and at its exit at two places into the river Avon, and the following are the results of the analysis of them :—

Constituents per gallon.	Raw sewage.	Effluent water.	Effluent water.
	Grains.	Grains.	Grains.
Solid matter in solution -	36·67	37·87	38·60
Chloride of sodium -	8·41	7·44	8·39
Organic matter - -	12·36	9·69	11·51
Ammonia - - -	4·43	1·28	1·28
Ditto organic - -	0·16	0·08	0·08
Nitrogen as nitrates, &c.	0·00	0·21	0·13
Oxygen required to oxydise - -	0·92	0·42	0·63
Matter in suspension -	1·28	0·32	1·15
Organic matter - -	0·64	0·13	0·58
Mineral ditto - -	0·64	0·19	0·57

On another occasion, when samples were taken, they yielded the following results :—

Constituents per gallon.	Raw sewage.	Effluent water.
	Grains.	Grains.
Solid matter in solution . .	43·30	36·11
Chloride of sodium . .	—	—
Organic matter . . .	6·10	2·49
Ammonia	3·841	0·480
Do. organic . .	0·120	0·080
Nitrogen as nitrates, &c. .	0·220	0·231
Oxygen required to oxydise	0.953	0·302
Matters in suspension . .	9·52	0·00
Organic matter . . .	4·48	0·00
Mineral ditto . . .	5·34	0·00

The farm, which has been worked for many years by enthusiastic irrigators, has been in several hands, who have invariably abandoned it at last, on account of the unprofitable results, and for the last two years it has been worked as a matter of necessity by the local Board of Health, who have spent about £5,000 upon it, and who pay a rental of £4 an acre for the land, which, with rates and taxes, amounts to £4 10s. an acre.

Last year the receipts were from £70 to £80 over the working expenses ; but this does not include the interest of the money borrowed, or the cost of superintendence.

Foot and Mouth Disease.—Three fresh outbreaks of this malady in the Dorchester division were reported on Saturday ; in that division alone it prevails on nineteen farms. Thirty fresh cases are also reported from Yeovil. In other districts of Dorset the disease continues to spread.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, SEPTEMBER 21, 1870.

THE BRITISH ASSOCIATION.

The address of the President of the British Association for the Advancement of Science—our Academy of Sciences—is always looked forward to with interest, and this year expectation has been on tip-toe as to the utterances of Professor Huxley. He has spoken, and his address will be everywhere read with intense interest—in many places with intense relief. He has admitted in set terms the doctrine that life, so far as we can trace, proceeds only from life. *Ex nihilo nihil fit* is a very old proverb, and after centuries of controversy science is coming round to recognise the truth of the adage. Not that Dr. Huxley altogether resigns the rather heterodox notion many expected him to advocate, for, after showing that science points clearly to the fact that life is the product of previously living organisms, he expressly stated that if he could look beyond the abyss of geological periods, he would anticipate seeing the evolution of living protoplasm from *not living* matter. We cannot dignify such an anticipation as a "philosophical faith." He does not deny that it is not a conclusion from the data before us. His own address throughout leads up to the very opposite conclusion, and the introduction of such a speculation jars upon us, as we calmly read his elaborate essay, like a loud discordant note amidst the murmur of soft melody. In fact, while Professor Huxley reasons carefully enough up to this point, and displays the docility of the philosopher to the teaching of science, here he appears to abandon himself suddenly to wild conjecture. Impatient of the limits imposed on human reason, he hazards a mere guess at the mystery which ever meets us. Of course, he is as free to guess as inferior minds ; but when it comes to guessing, it may well be that a child is as wise as a philosopher. Having said thus much, we need not follow Professor Huxley through his address. All our readers will find much in it to interest them, and we are glad to be able to present them in our present issue with a full *résumé* prepared for us by one of our own staff who attended the great scientific

congress at Liverpool, and who will further furnish us with a careful abstract of all the proceedings that especially interest our profession. This will exact a large portion of our space, but after all, the medical profession is unquestionably the most scientific, and a medical journal must of necessity have the largest number of scientific readers. Moreover, it is more important to have good reports of the British Scientific Association than of its feeble imitator, that confines itself to medicine only.

Notes on Current Topics.

About the War and Wounded.

The National Society has sent out sixty-two surgeons and sixteen lady nurses. It has forwarded 1,000 bales of material for their use, averaging some three tons per diem. The payments have been £20,000, and credit for abroad for £30,000 more.

In accordance with a resolution adopted by the Society of Medicine, of Marseilles, the medical men who have been called into military service, have been invited to place a list of their private patients in the hands of one or more of their brethren chosen by themselves, and the medical men who remain at home have undertaken charge of the patients for the benefit of their absent brethren.

The Prussian surgeons, it is said, have discontinued the use of charpie, and have replaced it by cotton wool, which is boiled with certain agents, and then dried in hot air.

The reduction in temperature on the Continent has caused the epidemics of typhus and of hospital gangrene to disappear.

The *Gazette Medicale de Paris* announces in its last issue that, in consequence of the impending siege, it ceases to be published for the present. The *Union Medicale*, on the other hand, announces that it will continue to be published and distributed to its Metropolitan subscribers until the bombardment (*Dii avertant*) shall render *communication* impossible.

Too good to be True.

The newspapers say that the Government intend to greatly increase the number of medical officers who are employed for the purpose of sanitary supervision under the Privy Council; in fact, the whole of the kingdom will be divided into sanitary districts, each under a medical officer with a salary of not less than £600 per annum. No doubt it would be true economy to prevent disease; but can we really hope for such a bold measure?

Winter Climates and the War.

We are assured by those who are personally acquainted with many inhabitants of Nice, that the disturbances there might have been anticipated, and that throughout the whole district annexed by Napoleon there is a dangerous excitement. It will be attempted to be shown by hotel and lodging-house keepers, and possibly by interested doctors, that only a few roughs have broken out and that they will be kept down. Prudent people will, however, refuse to locate themselves on the smouldering volcano, to say nothing of the difficulty of the journey. Mentone and Monaco are even more dangerous than Nice—in fact, a small rebellion broke out there last year. It is said by interested people that English persons and property are sure to be safe, but who can answer for such a mob of Socialists as that which a few days ago broke open the prisons at Nice and set the convicts free. We advise our bretheren to be careful how they recommend their patients to winter in any of the places named, and our advice is based on authentic statements by the last post that has reached London, and the representations of those who have had every opportunity of acquiring personal knowledge of the condition of affairs. Even Italy is safer than France. There are thousands of cases that would do very well on our own coast, and really this seems like a time when preference should be given to the many sheltered nooks of Old Albion.

Warm Clothing.

It behoves those of our brethren who have much night work, or long country journeys to make, to see after some additional clothing now that the season is altered and cold sharp winds invade us. How many of our hard-working practitioners fall victims at this season to diseases engendered through neglect, which a little foresight might have guarded against; when the miasma arising in fenny districts is most virulent, and the vicissitudes of the atmosphere from heat to cold most appreciable. Last winter the Messrs. McGee and Co., of High street, Belfast, introduced an admirable overcoat of their manufacture, which proved a great boon to the much exposed country practitioner. The nature of the material and the artistic workmanship revealed in its clever make and becoming shape, rendered it a general favourite as a most useful and comfortable garment. We hope to see Mr. McGee's coat reproduced this approaching winter, and worn by all threatened with chest affections.

Therapeutical Action of Cold Affusions in Typhoid Fever.

M. de Lambert, who has lately written at length on this subject, has arrived at the following conclusions:—

1.—Cold affusions are especially advantageous in typhoid, and the eruptive fevers.

2.—They act on the principal, and most constant phenomenon in these diseases, namely, the elevation of the temperature by diminishing it. They are, consequently, in the highest degree, anti-pyretic. They bring down the temperature from 0·5° to 3·0° (centigrade).

3.—They favour the restoration of a full, deep, and regular respiration.

4.—They stimulate the peripheral circulation by strong and rhythmical contractions of the capillary vessels, contractions caused by reflex action.

5.—They stimulate all the physiological secretions.

6.—They restore to the skin its suppleness, its moisture, and its healthy colour.

7.—They, in general, favour the appearance of the eruption, and recall it when it has disappeared.

8.—They calm cerebral agitation in awaking activity of the cerebral circulation; they suppress delirium, coma, and lessen prostration.

9.—They cause a general feeling of comfort, which allows the patient to sleep quietly.

10.—They diminish the frequency of the pulse by 8 to 20 or 30 beats.

11.—They relieve headache.

12.—Their anti-pyretic action lasts for two to six or eight hours.

13.—They should, as a rule, be repeated from two to four times in twenty-four hours.

14.—They are specially indicated in the severe cases of typhoid fever, or of one of the malignant eruptive fevers.

15.—They do not influence the duration of these diseases, but render them lighter, or lessen their severity.

16.—They are not indicated in all cases of these diseases without exception, they do not, therefore, constitute a general method of treatment to the exclusion of all other concomitant therapeutical means.

17.—They may be advantageously associated with application of cold bandages, or with the employment of cold lotion.

17.—Their application is easy, and is not attended by untoward results to the patient.

19.—Their methodical and rational employment is based on the principles of clinical physiology.

The Bone-Setter.

Our recent editorial annotation depicting the bone-setter, and showing the dangerous nature of practice followed by this worthy, together with the communication of Dr. Clarke, published recently in these columns, has been the means of eliciting much valuable information on the subject from various sources. Our attention has been directed to the following paragraph, demonstrating the ignorance of the bone-setting class, and published in the columns of an admirable contemporary, *The Lincolnshire Chronicle*:—

A Professional Opinion.—The following is a transcript, *verbatum et literatim*, of a certificate recently given by a gentleman of the profession known as that of a bone-setter. The original document may be seen at the office of this paper:—

The Milk of Diseased Cows.

We are informed by a well known physician, resident in a Midland county, in whose district the cattle have been infected with the *foot and mouth disease*, that he has traced cases of apthous ulceration of tongue and fauces, with a general disordered condition of system to the use directly, in many instances, of milk from diseased cows, and in others who consumed milk from a suspicious source. Upon enquiring further into the subject we find the milk given by cows suffering from foot and mouth disease is altered in character, as it is diminished in quantity. We are told the milkers notice its being ropy, and tenacious to the fingers, owing to the large quantity of mucus it contains. It is remarked to possess somewhat the appearance and taste of milk given by cows within a few weeks of calving. There can be no question of doubt respecting the alteration in character of the milk, and we believe we can implicitly rely upon the authority of our correspondent who assures us that the milk given by cows diseased is, if extensively used as an article of diet, sure to manifest its deleterious influence upon the system, and that delicate women and weakly children are more generally affected. In one farmer's house every member of the family suffered from *parasitic thrush*; they were consuming milk from diseased cattle, and the medical attendant ascribed the existence of *oidium albicans* to some *materies morbi* existing in the milk, for when the use of it was discontinued the mucous surfaces affected speedily recovered their normal state. So it has been noticed by others that when suspected milk was used and *aphthæ* were produced, that a discontinuance of the milk soon permitted the disease to yield to simple treatment. To direct the separation of infected cows, or to order that the milk which must be taken away from their udder, be given to pigs, is advice not likely to be followed since milk is so valuable a commodity, carrying with it so high a price in the market. We think, then, in every district the authorities should direct their attention to the subject, that they should enforce some stringent measure whereby the sale of diseased milk might be prevented, as we fear most persons are in happy ignorance of a disagreeable fact, and that when cows are infected the occurrence should be reported, and some understanding given or arrangement entered upon between the parties, whereby the sale to others, or the use by any of diseased milk may be prohibited and prevented. This is a subject of much importance, which we hope to find attended to by those whose province it is to regulate the sale and consumption of improper food.

Colour-Blindness and Railway Officials.

To Dalton and Herschel belong the credit of first directing attention to persons suffering from colour-blindness, who may even themselves be in happy ignorance of the fact, because of this peculiar condition of vision not necessarily defecting the eye or interfering with the ordinary requirements of sight. We understand that those practitioners who examine men for employment upon railways and who take the trouble of testing whether the person before him suffers from colour-blindness or not, discover it no unusual fact to find them erroneous in recognizing certain colour rays, and that the shades wherein most err are red, yellow, green and blue, the red being mistaken for yellow by some, the yellow for green, the pale green for cloudy white, and the blue for black, the very shades which all persons working upon, or connected with railways or holding situations wherein coloured lights are employed, as in vessels at sea, or light-houses should be perfect in, as a mistake might prove disastrous to many. Indeed, very few persons are perfect in their colour vision. Dr. Wilson, who is an authority on the subject, states that one person in every eighteen is colour-blind in some marked degree, and that one in every fifty-five confounds red with green. Any one of this fifty-five must needs be a dangerous person if entrusted with the working of coloured signals, accordingly it behoves railway companies to test periodically, through their medical officer, the condition of vision in detecting colours of their operatives, for if colour-blindness exists we know education of the eye or treatment will not improve it. We know a gentleman who always recognized light red as violet, and when light-

ning existed in the atmosphere the flash always assumed a violet hue to him. Men, then, who pace the deck of a steamer on watch, signal-workers and railway-guards should be even above suspicion of being colour-blind; for an obvious reason, and to avoid danger, their efficiency should be properly tested.

A Journalistic Nondescript.

If anything could render the position of the Council of the British Medical Association in relation to the journal, whose officials they are, more anomalous or less dignified than it is, the publications of that periodical for the last fortnight could not fail to do so.

The journal of the proceedings of the British Medical Association for the 11th instant contains, in an immense bulk of thoroughly unreadable matter, just one-third of a column of any matter relating to the Association. The remainder of the publication consisted almost solely of closely printed official regulations, and the issue of the 17th is largely occupied with similar matter.

We venture to inquire what may be the concern of the British Medical Association with such matter, and what is become of the proceedings of the Associations, Metropolitan and Provincial, which the journal is supposed to chronicle? and, lastly, what has become of the Council which permits the Association to be temporarily extinguished while the journal refreshes itself with a little trading?

The *Journal of the Society of Arts*, or the *Pharmaceutical Journal* are not permitted thus to set aside their duty, and, that the *British Medical Journal* should do so, conclusively proves that, in the Association, neither the Country Branches nor the Central Council are anything or anybody so long as the printer stops the way.

Over Crowding of the Irish Population.

By those who attach great importance to the influences, for good or for evil, of everyday domestic life on the uneducated classes, the condition of the Irish poor in respect of their dwellings may be quoted as accounting for the low degree of civilisation attributed to them. It is, indeed, hard to suppose that undisciplined minds, subjected at every moment to contact with squalor, irregularity, and slovenliness, shall be very deeply ingrained with respect for law, order and discipline. While we are quite of opinion that model dwellings cannot exist without model females to live in them, and that an improvident, lazy, or dirty household will infallibly convert the most charming of dwellings into a filthy grovelling cabin, yet it seems to be common sense that people who are really and willing to bring up their families in that cleanliness which is next to Godliness, ought to be afforded the chance of doing so, and not driven to herd in a filthy stye at an exorbitant rent.

The Irish Registrar General, in his last Agricultural report, says—

It is scarcely possible, both on social and sanitary grounds, to exaggerate the importance of improving the labouring classes; the Legislature has enabled the Treasury to grant loans for this most desirable object through the medium of the Board of Public Works. According to the census of 1861, the number of *fourth-class houses* in Ireland, each of which had but *one room for the entire family of* EVERY AGE AND SEX, was 89,374—and in these were living nearly *half a million* of persons.

It is evidently useless for the Treasury to put the means of providing improved dwellings at the disposal of money-grubbing tenement landlords, or lazy-minded tenants. Permissory powers are as useless, to such persons as Town Councils and Boards of Guardins. Why, then, should not a model lodging-house be provided at Government expense in every place where they are wanted, under Poor-law administration, and careful, but not officious, police control? The scheme at first blush looks feasible, and the objects are certainly worth the attempt.

Bristol and Clifton.

It is but fair to give prominence to the fact lately brought forward, that the worst slums of Bristol are in the Union of Clifton. This goes far to explain the disproportion observed in the health of the two places. Dr. Budd's attention is invited to the influence this fact would exercise on his statistics, which were supposed to show that there had been much less scarlet fever in Bristol than Clifton.

Our Navy.

The world has seen lately how much depends on the medical department of an Army. The Navy needs a medical service just as efficient. Yet it is a fact that men cannot be found to fill up the complement of navy surgeons. The public should be told why again and again. It is only because the authorities will not treat the medical staff as gentlemen, and will not keep the promises that have been made. England might have the finest naval medical service in the world by merely doing justice. Let the country know that on the slightest strain that service will surely break down through the refusal of the Admiralty to make the Navy, what it might be, the most attractive national service.

Life Assurance.

By the new Act, a company must not start without some paid-up capital, and must not cover bankruptcy by amalgamation. Thus two modes of swindling are guarded against. A more important provision is the regular publication of certified accounts. To publish incorrect accounts will be an indictable offence. Every policy holder will do well to satisfy his own mind by investigating the accounts of his office as soon as they shall appear, or, if he cannot comprehend the figures, submitting them to some friend who can. Intending assurers will have themselves to blame if they do not look into this matter before taking a policy.

The Bengal Medical Retiring Fund.

This is a fund which, when it started into existence many years ago, 1836, promised to medical officers of the Honourable East India Company's Service an annuity of £300 a year in rotation after seventeen years' service, provided that the applicant had paid the half value of the annuity. At first it was regarded as a great boon, but afterwards it was viewed with chagrin and vexation; now, by most of the subscribing members, most certainly by the juniors, it is looked upon as the curse of the service, as a dead loss, in fact, of £2,000 or £3,000. There are many juniors who will never obtain an annuity; unless, which

is not likely, they live far beyond the average age of man. And every sixpence they are now subscribing is passing away into a sinking fund, not one farthing's value of which can they or will they ever realize. The best placed members on the list of the fund cannot expect an annuity under twenty-six or twenty-eight years' service; the juniors may whistle for their's till doomsday.

The Delhi Gazette understands that the Governor-General in Council has been *memorialized* by a large number of subscribing members, who earnestly pray to be relieved of this penal incubus which must inevitably rob them of a large sum of money—the larger the sum the longer they continue to serve H. M. in India. There are many who would give up all claim to the fund, and to the money they have under compulsion subscribed to it, if they were only permitted to withdraw from it altogether and to cease to subscribe.

Tenure of English Poor-law Medical Appointments.

The Poor-law Board transmitted last week to the St. Pancras Guardians the following important communication in reference to out-door medical relief, and the construction to be put upon their recent order with regard to the permanency of appointment of medical officers. "Poor-law Board, Whitehall, September 8th, 1870. Sir,—I am directed by the Poor-law Board to acknowledge the receipt of your letter of the 1st inst., with regard to arrangements for affording medical relief in the parish of St. Pancras. The Board directs me to state that the provisions of the order referred to by the guardians only apply to medical officers who are appointed after the 29th instant, and that if the guardians prior to that date appoint the medical officers for a period of three months as suggested, their terms of office will cease at the expiration of that time. The Board, on the representation of the guardians, with reference to the temporary arrangements recommended by them, are prepared to assent to their proposal. The Board also direct me to state that they have been anxious to issue their order as to the regulation of dispensaries with the least possible delay, but that before doing so they considered it desirable that a certain number of dispensaries should be established and set in operation, so that the regulations might be framed with reference to the actual necessities of the case.—I am, sir, your obedient servant, Fras. Fletcher, Assistant Secretary.—To Mr. D. Fildew, Clerk to the Guardians, St. Pancras." Mr. Salter considered this communication satisfactory. He moved that it be received and entered upon the minutes, and that the out-door medical officers be re-appointed for a further period of three months, from the 29th of September to 25th December, 1870. The motion was carried, and the clerk ordered to write to the medical officers to know if they agreed to the arrangement.

The Velocipedist's Disease.

A correspondent enjoying an extensive field for observing professional velocipedists, directs our attention to the variety of diseases to which they are specially liable. Although our authority is pleased to designate the complaint *Velocipedist's Disease*, we find it nothing more or less than varicocele and a varicose condition of the veins of the leg. However, it is interesting to note that the working of a velocipede tends to produce so disagreeable a disease. We allow that a long continued obstruction of, or an undue amount of pressure upon the veins of the extremities will cause *varix;* still, we are inclined to believe that there must be some inherent weakness of structure as well existing. This opinion we find corroborated by a remark from your correspondent who states that the temporary pressure upon the veins through working the velocipede must be the cause, *per se*, for he observes when the pressure is removed and velocipeding dispensed with, that the tortuous condition of the veins of the scrotum and extremity recover their normal condition and all tenderness and swelling soon subsides. We recommend all who suffer from varix, or evince any sign or symptom of it appearing to lay aside their velocipede that further enlargement of the veins may be prevented, and if already distended that the contraction of their coats may be induced.

The Sanitary State of Lincoln.

We understand the sanitary state of Lincoln is in a very backward and deplorable condition. The appearance of the town built on a hill is apt to deceive, but a writer in the *Lincolnshire Chronicle* accounts for the bad health of the town to the houses being drained into cesspools, which store up the poison year after year. In only very few instances have these cesspools become filled, and consequently emptied because the sewage escapes through the porous layers of stone upon which Lincoln is built. Last week we learn enteric fever and scarlet fever broke out on the waterside. The medical officer states they are both of malignant character, and are probably occasioned by the putrid emanations from the river. Surely, with this testimony before them it is high time the local Board took action in the matter, and endeavoured to remedy an existing evil which is liable at any moment to break out virulently and affect the health of the whole community. It is not when disease presents itself, and poor people are infected that sewage wants attending to. We understand the Local Board are very obstinate in this matter. We recommend, then, as deaths occur from diseases traceable to wilful neglect of the gentlemen who sit upon the Board, that inquests should be held, and the thoughtless stupid members of it censured as they deserve. Some people require to be driven to do that which is proper. Let us hope the Board of Health of Lincoln will be quietly led by their medical advisers into doing that which is right, and has for its immediate object the welfare of the people in preserving the health of the town.

The Sewing-Machine and its effect on Health.

Communications from various sources reach us in corroboration of our remarks made recently on the Sewing-machine and its effect on health. The unfounded and absurd announcement promulgated by a contemporary that sewing-machines induced ovarian excitement of an undesirable character turn out as foolish as they prove groundless statements—the ephemeral supposition of some fertile imagination. The essence of our correspondent's letters is that frame-work-knitters—women who work stocking-frames—weavers in cotton-mills, and females who follow the occupation of machinists are, as a rule, very frequently the subjects as the case may be of menorrhagias, leucorrhœa, ovarian or uterine neuralgias, miscarriages, and unnatural labours; but we learn those who work the sewing-

machine, involve by their occupation, no more danger to health nor have any particular train of phenomena unnaturally increased than those who follow a sedentary occupation, and they account for this fact by the mild, agreeable, and less fatiguing nature of the employment compared with frame-work-knitting or calico-weaving. These conclusions arrived at by, and gathered from, men of large experience and great observation endorse, what may be termed, the pith of M. Decaisnes's communication laid before the Paris Academy in June last, who founded the tenor of his remarks after observing 661 workwomen.

Now that several medical men who have observed thousands of females so employed coincide with our Parisian authority, and bear us out in our observations, we cannot refrain charging our contemporary with heartless cruelty, and illogical sensation, in trying to injure a valuable form of employment. When the fox gets among the geese who will believe it after so much chimerical nonsense of the lowest order?

New Questions.

It is with great pleasure that we see that one of our respected contemporaries has devoted some leading articles to the subject of the *Functional Diseases of the Male Sex*. It has always been one of the marks of a want of supremacy in the medical art, that our profession has allowed its views on such questions to be over-shadowed by the miserable "purism" of the Judaiacal philosophy. There has been too, a sort of dominant priesthood among some of our fraternity, which has hitherto done the "dignity" for the rest, and kept us, of course, in wholesome ignorance and subjection thereby. Medicine must become henceforth a more positive science. It will not do for us any longer to try to make human nature square with the systems of manners framed long ago by ignorant priests. We are the true priests of the human body, and our duty is to find out, irrespective of all dogmas, what injures health, and how the *sound mind in a sound body* of the ancient philosophers is to be maintained. At present, the questions of male functional disease are treated by one or two members of our body, and, for the most part, left to the uninstructed or designing advice of "goody" tutors or traders. We must have no more of this; and hence, we congratulate our readers that there seems to be a day coming when nothing in medical art shall be considered "common or unclean." We shall endeavour soon to criticise the advice given in the articles referred to, and hope that some of our readers may join in the debate.

The English Poor-law Medical Officers' Superannuation Act.

At the request of a correspondent we publish the Superannuation Act which has just received the Royal assent, and also an Abstract of the clauses of the Act under which the rate of superannuation is regulated.

An Act to provide for Superannuation Allowances to Medical Officers of Unions, Districts, and Parishes in England and Wales, A.D. 1870.

WHEREAS it is expedient that provision should be made to enable superannuation allowances to be granted to medical officers of unions, districts, and parishes in England and Wales, who become disabled, either by infirmity or age, to discharge the duties of their offices:

Be it therefore enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

1. The board of guardians of any union or parish, and the board of management of any district, may, at their discretion, with the consent of the Poor-law Board, grant to any medical officer of such union, district, or parish, an annual allowance, under and subject to the provisions of the Act to provide for superannuation allowances to officers of the unions, passed in the twenty-seventh and twenty-eighth year of the reign of Her Majesty, chapter forty-two,* notwithstanding such medical officer shall not have devoted his entire time to the services of the union, district, or parish, and such allowance shall be paid out of the common fund of the union or district, or out of the poor rate of the parish, as the case may require, exclusively, and no contribution shall be made thereto out of any moneys voted by Parliament.

2. No allowance shall be obtained by any officer under this Act on the ground of permanent infirmity of mind or body unless a Poor-law inspector, or some person in that behalf authorised by the Poor-law Board, shall have first certified that in his opinion such officer has by reason of such infirmity become incapable of performing the duties of his office with efficiency.

Drugging the Drink.

Recent revelations disclose the fact that it is no uncommon practice for designing prostitutes who contemplate robbing some unfortunate wight entangled in their meshes, to drug the beer or porter being drunk in order to render their victim insensible that they may complete the object in view. With such a heartless and dangerous intention, we understand a certain class of prostitutes actually carries snuff regularly for the purpose of drugging as suitable cases offer and an opportunity is allowed them. The usual practice is to have the ale or stout "mulled," some ginger sprinkled over it and to this a piece of tobacco, or a tolerable dose of snuff is secretly introduced. We were told by an hospital patient who had the misfortune to be dosed, or in other words, poisoned, that after he drank a few mouthfuls of the liquor drugged, that he endured a rapid feeling of great depression, with the most intolerable nausea unaccompanied by vomiting, that he knew everything going on around, and while the cold perspiration trickled down his face, he had not the power left of moving

* Abstract of Clauses of the Act.—1. The Guardians of any Union or Parish, and the Trustees or Overseers of any parish incorporated under a Local Act, may, at their discretion with the consent of the Poor-law Board, grant to any officer who shall become incapable of discharging the duties of his office with efficiency by reason of a permanent infirmity of mind or body or old age, upon his resigning or otherwise ceasing to hold his office, an annual allowance not exceeding in any case two-thirds of his then salary, whether computed according to a fixed sum or to a poundage.

2. This allowance shall be payable to, or in trust for, such officer only, and shall not be chargeable with his debts or other liabilities.

3. No officer shall be entitled to such allowance on the ground of age who shall not have completed the full age of sixty years, and shall not have served as an officer of some union or parish for twenty years at least.

4. No grant shall be made without one month's notice in writing to every Guardian.

hand or foot. When being deprived of his purse and watch, he had an inward consciousness of the act being perpetrated, but did not possess the power to resist or call for assistance, and that it was only after being removed from the parlour of the public-house as drunk and incapable, that the intense sickness began to abate, and the great depression about the heart and chest to pass off. We have known it stated that when a number of young men meet together and they design the intoxication of a member of their party, that a pinch of snuff achieves their cruel object. In both cases that of the prostitute for gain, and that of the student for vulgar frolic; the practice is alike dangerous and criminal. The action of tobacco, its powerful sedative effect upon the heart, and the great depression it thereby induces, is only too well known, as it is too easily obtained for the practical purpose above described. However, we hope the police, and above all, public-house keepers, will be alive to the subject, and that magistrates will punish severely where the case is established.

We are enabled to announce that the next meeting of the British Association for the Advancement of Science will take place at Edinburgh.

We regret to hear that cholera is rapidly spreading at Havana.

The Baby-farming case is to be tried about the time our readers receive this number.

The Brentford magistrates have fined a farmer for not giving notice of the outbreak of foot and mouth disease among his cattle.

We underatand that the ex-Empress of the French, who is at present staying at one of our most healthy and fashionable watering places on the South coast, has almost recovered from the fatigue which had so materially affected her health, and, but for the annoyance she experiences from the obtrusiveness of the visitors who have flocked there since her arrival, would have made a much more lengthy stay. As it is, Hastings will shortly lose the presence of her ex-Imperial Majesty; and we sincerely trust that, profiting by the lesson this town has received, Torquay will pay that deference to the health and comfort of its illustrious visitor, as her unfortunate position and delicate state of health absolutely requires.

SCOTLAND.

Edinburgh.—It has been definitively arranged that the foundation stone of the New Royal Infirmary is to be laid on the 13th October by H.R.H. the Prince of Wales.

Glasgow.—Sir W. Stirling Maxwell, Bart., has given the munificent sum of £1,000 in aid of the University Building Fund.

Practical Method of disguising the Taste of Bitter Substances.—In the *Bulletin de Thérapeutique*, July 30th, 1870 M. Bouilhon suggests the chewing of a portion of liquorice root after taking sulphate of quinia, colocynth, aloes, quassia, and other bitters. The active principle of the liquorice, glycyrrhizine, seems to possess the property of nullifying and replacing tastes dissimilar to its own.

SPECIAL CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENT.

[THIRD LETTER.]

Paris, August 1870.

In a former letter I gave an account of the lectures of M. Charcot, at the Hospice de la Salpetrière, on the subject of disturbance of nutrition, caused by lesions of the spinal cord. In his next lecture the learned Professor spoke of certain cutaneous eruptions, arising sometimes in the course of progressive locomotive ataxy. M. Charcot observed that papular eruptions sometimes appeared with urticaria, h. zoster, and, more rarely, pustules. All of these eruptions had this in common, that they appear simultaneously, with certain exceptionally intense exacerbations of pain, "douleurs fulgurantes." The eruptions generally are seated on the course of the nerves, which are the seat of pain. The pains which are so marked in cases of sclerosis of the posterior columns of the cord, in all probability, he thinks, depend on the irritation they undergo in their passage through the interosseous foramina by some of the prolongations of the posterior roots. Another cutaneous affection, witnessed in like cases, is seen in the form of erythematous patches, on which soon are developed vesicular eruptions or bullæ, which soon turn to eschars. This secondary affection generally is seen on the nates; but may arise on all the parts of the trunk or limbs, which are for a long time submitted, whilst the patient is lying down, to a prolonged pressure. It is very different from all the very various eruptions observed on the nates in patients attacked with different diseases, all of which necessitate a long stay in bed. These eruptions, at one time like lichen, erythematous, pustular, or ulcerous, sometimes very like mucous plates, are most commonly occasioned by the frequent contact of irritating matters, such, for example, as urine. Just like erythematous and vesicular or bullous eruptions, these eruptions may become the starting point of veritable eschars. Their commencement, shortly after that of the primitive disease, and their rapid evolution, are two characters which only belong to the first.

On account of the interest attached to it, this affection would deserve certainly to be called by a proper name. The name "acute decubitus" has been proposed. Here are the first phenomena which occur in this affection in cases of apoplexy from hæmorrhage or softening:—1. At the outset there is simple erythema, sometimes of dusky hue, which yields to the pressure of the finger. It makes a striking contrast to the side opposite to the paralysed one, which remains free in cases of apoplexy from cerebral hæmorrhage. In rare cases we observe phlegmonous and very painful swellings, if the part has retained its sensibility. Next day, or shortly after that, the central part of the erythematous plate becomes the seat of one or more bullæ or vesicles, containing a liquid sometimes very abundant. These may appear on the heel, on the nates, the malleoli, the inner aspect of the knee, or the sacral region. The liquid is sometimes clear, sometimes reddish. The bulla bursts; the epidermis, raised up, is detached; and we then have before us a damp surface of lively red hue, or, in addition to this, strewed with bluish points or plates of a violet hue, which are caused by an infiltration of blood into the derma. The cellular tissue in such cases, and sometimes even the subjacent muscles, are invaded by infiltration of blood. These violet plates and the detachment of the epidermis extend rapidly in breadth, and soon at the points they occupy is produced a mortification, which, at first, is superficial, and then extends in depth. The eschar is formed, and the period of reaction and elimination commences, followed, in fortunate cases, by a period of reparation too often arrested in its development. Dr. Bright has figured in wax—and this figure is probably to be seen in Guy's Hospital Museum—the bullæ of this description observed in a case of paraplegia occurring from traumatic causes.

These eschars form a focus of infection, which occasions various accidents:—1. Putrid infection, whose capital symptom is a remittent fever, due to the septic intoxication which terminates so many spinal affections. 2. Purulent infection, with production of metastatic abscess. 3. Gangrenous embolia. In this last variety, thrombi, impregnated with gangrenous ichor, are transported to a distance, and give rise, when deposited in the lungs especially, to gangrenous metastasis, as described by Ball and Charcot in 1857. It must be remembered, however, that M. Foville has expressed the opinion, before these gentlemen, that a pretty considerable number of pulmonary gangrene cases observed among the insane were caused by the transporting into the lung of a part of the fluid which bathes the eschars. The mortification and ulcerative process goes on and attacks the deep tissues. Then the serous bursæ of the trochanters are sometimes opened, and the trochanters stripped of their periosteum, or the sacrum and coccyx are denuded. In this last case, the most grave complications may arise. In the first place, the pus and the ichor of the gangrene penetrate through the foramina, and, if the dura mater is intact, the fatty cellular tissue around it is alone bathed by the pus; or, again, if the dura mater is opened, we may observe the following accidents:—There may be simple ascending purulent meniugitis, or ichorous ascending meningitis. In the last case, a greyish fetid pus surrounds the meninges, and the cord itself, in its whole length; we find it at the base of the brain, in the fourth ventricle, the fissure of sylvius, and the lateral ventricles. The brain substance is tinged at its surface and sometimes in its depth with a clay colour, which has, on several occasions, been mentioned and described under the name of gangrene of the brain. But, in reality, this is merely a phenomenon of imbibition. This is so true, that in cases of cancroid of the face, which extend to the dura mater, this same clay colour has been remarked limited to the anterior lobes of the cerebrum at the point corresponding with the bottom of the ulcer. We observe, especially, cases of this kind in the apoplexy which follows on hæmorrhage into or softening of the brain; but they may occur also in meningeal hæmorrhage, in thickening of the meninges, and in cases where cerebral tumours give rise to apoplectiform attacks. It has its seat generally, or, at any rate, predominates, in these different circumstances on the nates of the paralysed side. It frequently comes on from the second to the fourth day, sometimes further on. On account of the conditions in which it arises, it rarely goes so far as to confirmed eschar. We, perhaps, never see it in cases which should terminate in a favourable manner, and, consequently, it constitutes a sign of the most distressing augury. This sign is scarcely ever fallacious; and as it is possible to remark its appearance from the very first day, it, on this account, is of great value in prognosis in difficult cases. A considerable diminution of the central temperature, remarked at the onset by means of the thermometer, is, as far as is known, the sole sign which, in cases of hemiplegia coming on suddenly, can rival, as far as prognosis is concerned, in importance with this.

Pressure cannot be looked on as an important element in the causation of such lesions, since this is equal for both nates; and frequently, although the patient is carefully turned on the non-paralysed side during the great part of the day, this precaution in no way modifies the production of the eschar. Besides, what, in such a case as this, can be the influence of a pressure which has only been exercised during two or three days? We cannot, again, invoke as a cause the contact of the urine, &c.; even when carefully prevented from soiling the patient, the eschar will arise. According to M. Charcot, the cause of this disturbance in nutrition will be found to reside in an irritation of certain regions of the cord, produced at a distance as a kind of echo, under the influence of the brain lesion. In cases where there is affection of the spinal cord, the position of this affection is variable, Sometimes, and most frequently, it is median or bilateral; and it is at the sacral region or at the region of the trochanters that eschars are formed. Sometimes it is unilateral—for instance, in the somewhat rare case of spinal hemiplegia—and then the eschar generally occupies the side opposite to the spinal lesion. And, lastly, all the parts which suffer the slightest pressure—the heels, the bodies of the limbs, or the internal aspects of the knee—may have lesions of the kind. As a general rule, it may be said that the spinal lesions which produce eschars such as these are the same as those which give rise to acute muscular atrophy and other troubles of nutrition of like kind. It is important to remark that all these consecutive affections appear often simultaneously, as if they arose from a common cause. We may mention, firstly, the traumatic lesions of the spinal cord. A rebel, whose case is mentioned by M. Vignès, received, between the ninth and tenth dorsal vertebra, a sword-cut, which wounded, especially, the left side of the cord. Soon after this, paraplegia ensued, chiefly on the left side. The twelfth day after the accident, there appeared on the left side an arthropathy, characterised by a painful swelling of the knee with hydrarthosis; and on the thirteenth day an eschar on the left nates. In the third place, fractures of the vertebral column may be referred to. In numerous cases cited by Brodie, &c., we see eschars appear on the first, third, seventh, or twelfth day, whether or not there was anæsthesia of the parts whose motion was paralysed. The formation of eschars is, in such cases, sometimes accompanied by symptoms of irritation of the cord, such as spinal epilepsy, passing convulsions, or acute pains. In all these cases just enumerated there is attrition, red softening of the spinal cord, and, in particular, of the grey matter to a certain extent; and it is to this circumstance that we must doubtless attach the production of the eschars as that of the acute muscular atrophy.

(To be continued.)

Correspondence.

DR. DRYSDALE'S PARISIAN LETTERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I think Dr. Drysdale will agree with me that we have both digressed from the original subject of Prostitution and the Contagious Diseases Acts, and taken unfair advantage of that universally-recognised and admired liberty and independence of principle which characterises the method upon which the MEDICAL PRESS is conducted, when we find ourselves at issue upon a religious question, which should not be argued in the columns of a scientific journal for very obvious reasons.

As far as that portion of Dr. Drysdale's first Parisian communication refers to me, I trust I may, in conclusion of the subject, be permitted space to reply, and in doing so, I cannot refrain expressing surprise at the ungenerous and inaccurate conclusions arrived at by my friend. I would not take the trouble of answering them were I not thoroughly impressed with the fact that there is no truer friend of Ireland than Dr. Drysdale himself. In the past he has proved it without doubt, and I can only account for his inaccuracies by the fact that he wrote confusedly and thoughtlessly in Paris amidst the din of the war drum and the revolutionary cry of red republicans.

1stly. I never attempted defending chivalrously the clergy of the Irish Church,—they are only too able to defend themselves when the occasion requires it,—but I did ascribe the spirit of true religion infused into the breasts of the people keeping down profligacy, and doing such successful battle against prostitution in Ireland. I might have gone further, and compared England, with its wholesale murderers, poisoners, and abortion-mongers, with much-maligned Ireland, where the worst crime is "*tumbling*" the tyrannical landlord in the hour of cruel oppression; but the galling chain of serfdom explains, whilst it excuses much that is done by him who is robbed of hearth and home, and driven from the soil of his fathers to take refuge on a foreign shore.

2ndly. The physiological error committed by Dr. Drysdale is of so delicate a nature that I dislike alluding to it; but there is no alternative left me. *It is the spiteful remark of a man who knows better;* accordingly there is no excuse for blunder. Because the Irish Church refuses to annul the holy tie of matrimony to suit those who advocate facility of divorce in preference to Him who taught that those whom God joins together let no man put asunder, Dr. Drysdale fires a single shot home to the hearts of the clergy as cruel and illogical as it will be pleasing to the enemies of true religion; but every physiologist knows the fallacy of the argument. Dr. Drysdale leaves no alternative between matrimony or sexual intercourse of some kind and the disgusting practice of masturbation. To the libidinous-minded, granted; but surely allusion to the dirty subject suffices, without further explanation of the absurdity and ridiculous nature of the unclean belief advanced. Dr. Drysdale might as well preach that the mammary gland of one of his fashionable lady patients in the West-End should be constantly secreting milk, as tell us that the testes should be ever in action, or that the *vesiculæ seminales* should be ever distended. Dr. Drysdale knows better. MacMahon's troops smashed their *chassepots* sooner than the invading Prussians at Sedan should possess them. Dr. Drysdale tries the same plan: catches at illusory straws when he finds his facility of divorce sentiments passing down so gracefully to Avernus.

I hope Dr. Drysdale will not consider me over severe. I could not deal with the subject otherwise than in a tone of hard dissent. I retain my high opinion of him as a physician of good ability, as a man who has done much to benefit his brethren and exalt his calling, and, above all, notwithstanding his ungenerous sneer across the straits of Dover, a true friend at heart of the Irish Celt, whom he has ever placed on the same footing as the Anglo-Saxon.

One word, and I have done. Dr. Drysdale will join with me in offering our thanks to the Editors of the Medical Press, who are ever ready to allow their valuable journal to be the medium of doing that which is impartial and just, regardless of sect or person.

It is the only journal our profession possesses as such: accordingly we should value it the more, and not take undue advantage of its independent workings. That we have both wandered from our original subject there is no disputing, whilst the accidental introduction of the religious element is to be deplored; but "out of evil springeth good."

I am, &c.,

J. Waring-Curran.

Osman House, Sutton, Notts., Sept. 14, 1870.

THE POSSIBILITY OF CELIBACY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—You, with your usual impartiality, will please give insertion to the following in your deservedly-popular and truly independent journal.

I don't undertake to answer for, nor have I the slightest intention of taking the pen from Dr. Curran's hand, who is able to use it in a masterly, well-tempered, unprejudiced, and gentleman-like manner; but, as an humble member of the profession, I feel impelled, by a sense of right and spirit of fair play, to pass a few remarks on the correspondence (which has been published in the Medical Press and Circular) between Drs. Waring-Curran and Drysdale.

I am inclined to think that Dr. Drysdale has dealt rather unfairly with Dr. Curran in making the broad assertion that Dr. Curran has chivalrously defended the clergy of his native country. Dr. Curran states that there must be *something* remarkable in that religion, which so characteristically fosters *virtue* (or chastity), and suppresses such an amount of crime. That is evidently, and without an approach to sophistry, the simple meaning of the sentence referred to.

Dr. Drysdale must have paid very little attention to the study of metaphysics, when he puts the celibacy of the soldier and priest on an equality (or in the same category). We all must admit that mind, education, circumstances, and the various contingents connected with our existence have a vast deal to do with, and exert almost a mesmeric influence, in the regulation of temperament and formation of habits.

It appears the greatest conceivable stretch of a biassed mind to institute a comparison between both classes, even admitting the truth of the line of the Roman poet, "Si naturam furca repellas, tamen recurrit."

The soldier, in most instances, is one who is reared up in an immoral atmosphere, so to speak, his unchecked nature and surrounding circumstances tending inevitably to develop the coarsest passions.

The Catholic clergy, on the other hand, are, from their boyhood, imbued with a love of chastity, and are selected by their parents from amongst their families as manifesting the keenest appreciation of *virtue;* and from the time they handle the Latin grammar until they finish their course of studies, they are removed away from all circumstances and associations which would cast a stain on a pure mind.

The course of studies they have to pursue comprises all the requisites for the development of the most refined and noblest attributes of the *thinking principle*, and make mind to dust superior, and, consequently, must impress them with a detestation of vice, and a disgust of that degrading habit which Dr. Drysdale would insinuate. In fact, the whole *preparation* for the *arduous* profession of their adoption consists of a *training* for warfare with depravity of the intellect, and they enter the arena of public life with the sole determination of suppressing sensuality in all its shapes and forms. I state these facts as being one who studied with a great number of the clergymen (of that Church which Dr. Curran has complimented), and sharply observed their propensities; and I am confident that they have as great an abhorrence of indulgence of the sensual proclivities as Dr. Drysdale has of *holy water*.

Introducing what may not be considered appropriate in a medical journal in this advanced age of ours, but which is always refreshing to a believer's mind, and which cheers him on his rugged path, viz., a text of Scripture, which production Dr. Drysdale may smile at as being a structure too complex for his way of thinking, complex as is his way of thinking on social questions:—

Matthew, xix chapter, 12 v.—"For there are eunuchs who were born so from their mother's womb, and there are eunuchs who were made so by men, and there are eunuchs who made themselves eunuchs for the kingdom of Heaven's sake. He that can receive it, let him receive it."

The profession would feel very thankful to Dr. Drysdale for an explanation of the foregoing, as he is such an adept in theological codes.

In reference to Dr. Drysdale's opinion of the theological dogma, "un peché mortel," to restrain the numbers of a family by any means save that of *abstinence*, although being a junior member of that profession which Dr. Drysdale so pre-eminently ornaments, I would consider any other means of restraining the numbers of a family as most deteriorating in the moral sense, and subversive of all the innate sense of delicacy and rectitude which actuates the human breast. As for this doctrine of the Catholic Church alienating most men and women from the confessional, I, for the life of me, cannot understand. I suppose he (Dr. Drysdale), being outside the pale of the Catholic Church, and being completely opposed to her tenets, cannot possibly be looked on as a high authority as to what may attract to, or alienate from, the confessional.

I maintain that, when medical men enunciate principles which are supposed to ameliorate the condition of, and raise their fellow men in, the social scale, they ought not to be of that class which, instead of tending to make the "honest man" the man of noble mien, would make him of acne-ornamented visage, with *nature frustrated* stamped on his brow.

I would respectfully suggest that Dr. Drysdale would leave theological problems and the weighing of sins, "un peché mortel," &c., to properly-accredited ministers of religion, and let them amuse themselves in doing so,—even if Dr. Drysdale does not believe in their office—and leave the improvement of his kind (although he intends well) to others until he may be inspired with other means to attain the object, besides those means that would upset the very principles which bind society together.

Yours faithfully,

W. F. Fenton,

L.R.C.P.E., L.R.C.S.I., &c.

Clogheen, September 3, 1870.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In your issue of August 31st, there appears a letter from Dr. C. R. Drysdale, a portion of which cannot fail to be extremely offensive to many Irish practitioners. I allude to that part in which he speaks of the Catholic clergy.

It will make but little difference to those gentlemen whom Dr. Drysdale condescendingly designates "our Catholic

brethren of the Church" as to whether or not he agrees with them on the two points to which he refers; but there is, at least, one member of the laity who considers it a deliberate insult to his religion to have any of its tenets spoken of as a "silly doctrine," and marriage, which is, in the eyes of Catholics, a most holy sacrament, treated of in such slighting terms.

With excellent taste and gentlemanly feeling, Dr. Drysdale classes together soldiers, who are, as a rule, the refuse of society, and priests, who are, as a rule, educated gentlemen, and just as incapable of the vice to which he alludes as are, I should hope, the unmarried clergy of any other denomination.

Dr. Drysdale states that Dr. W. Curran chivalrously defends the clergy of his native country and their dogmas. All honour to that accomplished gentleman for so doing. He has, at least, the hearty good wishes of an

IRISH DISPENSARY DOCTOR.

P.S.—I enclose my card, but not for publication.

*** We insert these letters as a set-off to the obnoxious statements of Dr. Drysdale's which our correspondents have unfortunately thought fit *more Hibernico* to convert into a religious controversy. The "Irish Dispensary Doctor," who is so good as to afford us the results of his valuable experience as to our editorial duties, and to demand an apology from us for giving space to Dr. Drysdale, appears to be quite ignorant that, while the responsibility of unsigned letters is ours (and we have, therefore, availed ourselves of our right to strip his own communication of unnecessary and irrelevant matter), we have no authority to refuse to an author who attaches his name to his communication perfect freedom of speech so long as his use of the privilege is neither immoral, libellous, nor nonsensical. We close the correspondence now in obedience to the recollection that we are, to a considerable extent, catering for the profession of an unfortunate country, where the very wind blows either Protestant or Ultramontane, and the air of Heaven is equally compounded of the bigotry of Orange and Green. If our correspondents will only let us alone, we do not desire to know that such a word as "religion"—that ill-used watchery of every sort of unchristian rancour—exists at all.—ED. M. P. & C.

THE WAR AND THE WOUNDED.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I send you an extract from a letter I received to-day from my son, who went out to Gelsenkerchen, a town near Dusseldorf, to assist in the care of the wounded sent to the hospital of that town.

Yours truly,

J. W. MARTIN, M.D.

Portlaw, September 6, 1870.

"I went, the morning after my arrival, to the hospital, when I saw more gun-shot wounds than may ever fall to my lot to see again in the course of my life.

"There were several curious wounds: one man received the ball under the right clavicle; it came out between the posterior edge of the scapula and the vertebræ, and from the position, must, I think, have passed through the apex of the right lung. He is, however, convalescent, and will soon be off to duty again. In another case, the ball entered the back of the hand below the wrist joint, and came out on the palmar aspect of the fore-arm near the elbow. Strange to say, there was no fracture or wound of large vessels, and he is recovering rapidly. A third received the bullet just above the axilla, it escaped at the elbow, passing very close to the axillary and brachial arteries, and it looks strange, when dressing him, to see the water syringed into the wound above escape below. Dr. Wheitz is very civil to me. I go to the hospital every morning, and dress any amount of wounds. There is one very bad case, where the bullet entered the knee-joint; but we can neither resect or amputate until the fever subsides, when I fear the leg must come off.

"The treatment is simple: all the wounds are syringed with decoction of camomile. Charpie is then applied, and covered with simple ointment and moderately tight bandage, and in this way the wounds recover very rapidly. Very few new cases have come since I arrived here, but we expect them every day. They have got up a small hospital of ten beds, of which I shall have sole charge.

"Your affectionate son,

"ALFRED H. MARTIN."

Gelsenkerchen, Sept. 2, 1870.

Use of Carbolic Acid.

THE medical journals of Germany are largely occupied with reports and discussions on Lister's method of treating abscesses and compound fracture, the balance of opinion being strongly in favour of it. A case is mentioned by Dr. J. Steinitz (*Inaug. Dissert. Breslau*), of poisonous symptoms being caused by the application of the acid to a large abscess of the thigh. After two days, severe vomiting came on; the urine was almost black, and showed distinct traces of the acid. After being omitted for four days, the same treatment was again resorted to with a good result.

In the report of the General Hospital in Vienna, for 1868, Prof. Hebra gives his experience of the use of carbolic acid internally in various skin diseases. He found the remedy generally well borne, even in large doses. In cases of psoriasis a cure is often attained in as short a time as three weeks. In prurigo the tormenting itching is mitigated in an astonishingly short time.

Medical News.

Apothecaries' Society of England.—At a Court of Examiners, held on the 15th instant, Mr. B. S. Ringer, of the Metropolitan Free Hospital, was admitted a licentiate. Messrs. A. R. Lee and Francis W. H. Popham, of University College Hospital, Joseph Shaw, of St. Bartholomew's Hospital, and Frank Wacher, of Guy's Hospital, passed the primary professional examination.

Metropolitan Poor-law Association.—It was moved by Dr. Dixon, seconded by Dr. Pinder, and carried unanimously, "That Dr. Dudfield's resignation be accepted with great regret, and that the best thanks of the Council be tendered to him for the able and willing services which he has at all times rendered to the Association, and also for the invariable courtesy and kindness which characterised the discharge of his duties as Honorary Secretary for the past four years."

Hambro' Wine.—Under the title of "Good News for the Faculty," Ridley's Circular of Sept. 10th says: "On the 1st inst. no less than 11,214, and on the 6th inst., 11,075 gallons of Hambro' "Sherry" were paid duty on at the London Custom House, upwards of 10,000 gallons on each day being cleared by one firm, Messrs. W. and A. Gilbey.

"Died from the Effects of Improper Food."—This somewhat remarkable verdict was recently recorded in the Brighton newspapers, and is worthy of notice, because it states the facts of the case under investigation upon the occasion of an inquest referring to the sudden death of an infant. Under similar circumstances the verdict is generally "Death from natural causes," the truth being that the "causes" are very *unnatural*, when death arises from ignorance or neglect of the grossest kind. In the case alluded to, the medical witness did his duty, and the verdict as above stated was the result. It would be well for humanity's sake if the members of the medical profession, when called upon to give an opinion, would, in every case of the kind, state the facts as they find them, and, when death occurs from intentional starvation, or the use of improper food, let us not have verdicts of "Natural death," or "Convulsions from teething," or any of the numerous apologies for verdicts of "Manslaughter," which in many cases would be the just and proper result of such inquiries.

Lady Doctors.—Lady Amberley has offered to women desirous of studying medicine a scholarship of £50 a year, tenable for three years, to be awarded next month at Edinburgh by competitive examination.

Lithotomy Forceps.—The last forceps constructed under the advice of the celebrated Surgeon M. Amussat, are so arranged that the branches when in the bladder, may be brought to a right angle with the handles, so as to seize hold of the stone in the fundus. The mechanism consists mainly in a rack worked at the junction of the branches.

NOTICES TO CORRESPONDENTS.

NOTICE.—We are compelled to hold over several interesting letters, amongst which is one from our Special Correspondent in Paris.

POOR-LAW MEDICAL REFORM.

To the Editor of "The Medical Press and Circular."

SIR,—Will you permit me, through your columns, to remind my professional brethren interested in this important question, that Dr. Brady has resolved, aided by a distinguished Member of the House of Lords, to introduce a Bill in the next Session of Parliament, having for its object a very considerable reform in the administration of medical relief to the poor, and largely affecting the status of Poor-law Medical Officers.

In order to strengthen his hands in every possible way, I would appeal to all my brethren who are in a position so to do, to forward me a statement of any facts which they may consider useful, in demonstration of the inefficiency of the present system, whereby vast sums of money are yearly squandered in dealing with the consequences of sickness, which applied to its prevention, would result in an enormous saving to the ratepayers. In using any such information, the names of the contributors will be in every case withheld, unless distinct permission to publish them be given.

As it is most desirable to collect any such information without delay, I would urge such gentlemen as are willing to assist, to communicate with me as early as possible.

I am, Sir, yours obediently,

33 Dean street, Sept. 10th, 1870. JOSEPH ROGERS.

CHAIR OF NATURAL HISTORY IN THE UNIVERSITY OF EDINBURGH.—In consequence of continued indisposition, Professor Allman has decided to resign the Chair of Natural History, which he has held since 1855. Dr. Allman suffers from a bronchial affection, and has been recommended a residence in the South of France. This resignation will be officially intimated to the Senators immediately, to allow the winter arrangements to be made. The names of several eminent men are mentioned as likely to seek the appointment. The Crown has the patronage of this Chair.

ROYAL INFIRMARY.—There has not been a case of typhus fever admitted since July 21st. The few cases of fever admitted since then have been principally relapsing, but some enteric.

GEOGRAPHY OF DISEASE.—We are glad to learn that the Lord Commissioners of Her Majesty's Treasury have intimated to Mr. Haviland, through the Registrar-General, their approval of a grant of money being paid to him for the expenses incurred by him in correcting the registration maps of England and Wales. By our advertising columns it will be seen that Mr. Haviland will give a course of lectures on the "Geographical Distribution of Disease," at St. Thomas's Hospital, during the approaching Winter Session.

A NEW CHAIR IN GEOLOGY AND MINERALOGY.—We hear that it is the intention of Sir Roderick Murchison to found and endow a Chair for the cultivation of these sciences at the Edinburgh University. Six thousand pounds is the sum named as likely to be given by Sir Roderick for this purpose.

CUI BONO?

To the Editor of "The Medical Press and Circular."

SIR,—"There is always some man of whom the human viscera stands in greater need than of any other person, who is supposed, for the time being, to be the only person who can dart his pill into their inmost recesses, and bind them over, in medical recognisances, to assimilate and digest." Granted; but what futile imagination ever could have conceived the ex-Emperor of unhappy France sending for one of the staff of St. George's Hospital, other than the editor of the "Roasted-Apple Association Journal." It is humiliating, but true, the lesson taught by our admirable contemporary, the *Graphic*, who very plainly tells us of certain persons not only circulating untruthful reports, but revealing, for the sake of vulgar applause, professional information which should be confidential. I commenced with Sydney Smith, and I terminated by reproducing his Mr. Brown, who, be it remembered, danced with such alacrity and vigour, that he threw the Queen of Naples into convulsions of laughter, which terminated in a miscarriage, and thereby changed the dynasty of the Neapolitan throne. I hope a similar fate is not impending the Roasted-Apple Association.

I am, Sir, CANTHARIDES.

Member of a *Vox et Prætera Nihil* Association.

PODALIRIUS.—You are quite correct. The author of the letter to which you refer labours under a delusion, and the editor of the Journal appears ignorant of the fact that a fractured collar-bone does not come within the extra system, and that the Poor-law Board do not sanction a fee for such an injury.

J. M. D., Halifax.—The "Midwifery Notes" are interesting, and will appear as soon as space permits. Shall be happy to receive the case of "Aortic Aneurism," of which you gave a slight outline, and sent us a photograph.

DR. ANDOTTS SMITH.—Your communication is accepted, and will appear as soon as space permits.

DR. MARTIN.—Thanks; proofs will be sent you in due course.

F.R.C.S. "On the Celibacy of Priests."—We are sorry to refuse insertion to your letter, but this is not a religious journal, and our space is already too much occupied with matters professional, for theological disquisitions. Our columns are open impartially to you, as to every member of the Profession, upon subjects pertaining to it. We having nothing whatever to do with the profession of your faith, and the fact of your belonging to *this* or *that* creed, would not influence us, or cause a departure from our firm rule of independence and impartiality. We commend to the attention of our correspondent the admirably temperate letter of Dr. Fenton in another column, and whilst we, perforce, allow reference to religion when it is affected by the question under discussion, we at the same time cannot permit a theological controversy.

CAUTION.—The Terras Tin Mining Company, Limited.—We think it right, in the interests of our readers, to caution them against persons calling themselves Messrs. Mackenzie and Co., Share Brokers, of Winchester Buildings, London, and advertising extensively in the country papers to sell shares in the above-named company "at £2 10s., which will be worth £10 within a month." An order for the insertion of their long advertisement in our columns was sent to one of our branch offices; but before allowing such of our friends as have money to invest to part with it in reply to so alluring an advertistment, we instituted enquiries, and find that the individuals who so pompously describe themselves as of Nos. 1, 2, and 3 Winchester Buildings, have—with the permission of a second party, who occupies an office about the size of a cupboard at the top of one of these houses—the privilege of receiving letters addressed as above, which, unfortunately for the poor victims, were not a few by Monday's post, they thus fleece the credulous, and by being *not known* when sought after, evade the law. We have, therefore, no hesitation in characterising the whole affair as "a gross swindle," and feel thankful that we are able in time to protect our subscribers from what has doubtless proved to many through the insertion of the advertisement in other journals, a *Tin Mining Company* of a very objectionable sort.

THE LADIES AND THE WAR.—Mrs. Josephine E. Butler, a clergyman's wife and a distinguished *lecturess* on syphilis and cognate sexual matters, has undertaken to *protest* the Prussian forces out of the field by her infallible *panacea* female votes, and has favoured us with a copy of the document to which she solicits signatures. We do not advise sensible Englishwomen to submit themselves to a similar snub to that administered by an Irish judge to a flippant lawyer who commenced a remonstrance, "My Lord, I protest." "Well, sir, protest, and go about your business.

VACANCIES.

University of Aberden—Three examiners for graduation in medicine.
St. George's Dispensary, London, W.—Hon. Physician-Accoucheur.
Leeds Public Dispensary—Physician.
Kirkaldy Union, Fife—Medical Officer.
Sherbourne Union, Dorset—Medical Officer.
Kells Union, Nobber District—Medical Officer. Salary, £100. (See advt).
Applecross Union, Ross—Medical Officer.
Tredegar Ironworks—Assistant Surgeon. Salary, Indoor, £100.
Westminster Hospital—Resident House-Physician. Board and lodging, but without salary.
Kidderminster Infirmary—House-Surgeon. Salary, £150, with residence.
Liverpool Dispensaries—Resident House-Surgeon. Salary, £140.
Kingsbridge Union—Medical Officer. Salary, £25, *to include medicines, attendances, surgical appliances, &c.*
Narbeith Union—Medical Officer. Salary, £35, with extras.
Leicester Dispensary—Two additional medical officers. Salaries dependant upon receipts from free members of the Association.
Surrey Dispensary—House-Surgeon. Election 26th inst.
Bolton Infirmary—House-Surgeon. Salary, £120; with residence and partial board.

APPOINTMENTS.

BAKER, O., L.R.C.P., House-Surgeon to the York County Hospital.
BUSBY, Mr. A. R., Resident Medical Officer to the Royal Hospital, Bath.
EVANS, O., M.R.C.S., Medical Officer for the Pentrefoelas District of the Llanrwst Union, Denbighshire.
FREEMAN, D., M.R.C.S. Surgeon to the St. George Dispensary.
FURLONG, Dr., Demonstrator of Anatomy at the Catholic University, Dublin.
HAYES, P. J., L.R.C.P.Ed., Senior Demonstrator of Anatomy at the Catholic University, Dublin, has been appointed Medical Registrar.
HOGG, A. J., L.R.C.P., House-Physician to St. Bartholomew's Hospital.
HORSFALL, J., F.R.C.S., Surgeon to the Leeds Public Dispensary.
HOYLE, R. C., L.R.C.P., Medical Officer to the Barnstaple Union.
MANNING, F. N., M.D., Inspector of the Insane of New South Wales, and Superintendent of the Hospital near Sidney.
SECCOMBE, E. H., M.B., Assistant Medical Superintendent of the Royal India Lunatic Asylum, Ealing.
TAYLOR, F., M.B., Demonstrator of Anatomy at Guy's Hospital.
THOMAS, Mr. A., a Junior Resident Medical Officer to the Royal Free Hospital.
WALKER, T. A., M.R.C.S., Resident Medical Officer Dudley Dispensary
WALL, Mr. A. J., a House-Surgeon to St. Mary's Hospital.
WHITTLE, A., M.D., Physician to the Stanley Hospital, Liverpool.

Marriages.

SARGENT—PEARCE.—On the 6th inst., at Holsworthy, Devon, Henry E. Sargent, M.D., of Poliphant, Launceston, to Anna Maria Clara, only daughter of Thomas Pearce, Surgeon, of Holsworthy.
STEPHENS—BENNETT.—On the 14th inst., at Falmouth, R. F. Stephens, Surgeon, of St. Austell, Cornwall, to Bessie, daughter of the late John Bennett, Esq., of Redruth.

Deaths.

FEARN.—On the 8th inst., at Samaden, Switzerland, S. W. Fearn, F.R.C.S.E., a Consulting-Surgeon to the Derbyshire General Infirmary, Derby.
HALL.—On the 4th inst., at Teignmouth, Mary, widow of the late Richard Hall, M.D., Surgeon to the 7th Dragoon Guards.
LEARED.—On the 7th inst., at 10 Old Burlington street, London, the wife of Arthur Leared, Esq., M.D.
MACAULAY.—On the 1st inst., at Liverpool, Dr. Duncan Macaulay, aged 78.
OWEN.—On the 8th inst., at Brixton, Lydia, wife of J. Owen, M.D.
STURGES.—On the 6th inst., Charles Sturges, M.R.C.S., L.S.A., aged 62,

DOWNPATRICK BOARD OF GUARDIANS.

PARLIAMENTARY GRANT FOR MEDICAL AND EDUCATIONAL PURPOSES.

THE Clerk read the following letter :—

Poor Law Commission Office, Dublin,
26th August, 1870.

SIR,—The Commissioners for Administering the Laws for the Relief of the Poor in Ireland transmit to you herewith a draft on the Bank of Ireland for the sum of £288 3s. 4d., being the balance of the amount payable to Downpatrick Union of the Parliamentary grant for medicinel and educational purposes in Unions in Ireland in the year ending 31st March, 1870, as shown in the accompanying statement, together with the amount of the deficiency in previous remittances on account of the grant for the year ended 31st March, 1869. The Commissioners observe that the statement for the year shows that the claim for medical purposes exceeds the estimate by £74 14s. 9d., which is mainly caused by the large expenditure for medicine in the workhouse, amounting for the year ended 25th March, 1870, to £215 16s. 10d., while the average expenditure for the three years ending 29th September, 1868, was only £109.

It also appears that in the Downpatrick Dispensary District the expenditure for medicine for the year ended the 25th March, 1870, was £71 4s. 10d., or 1s. 4d. per head on the number relieved for the year ended 29th September last, the average for all Ireland being only sevenpence.

It further appears that the cost of medicines for the Strangford Dispensary District has also been large, being £58 2s. for the year ended 29th September last, or nearly 2s. per head on the number relieved, viz., 592 ; and the Commissioners request that the Medical Officers of the Workhouse and of the Dispensary Districts referred to may be called upon for their observations on the subject. —By order of the Commissioners,

B. BANKS, Chief Clerk.

THE MEDICAL OFFICER AND THE BOARD.

The Clerk read the following letter addressed by the Commissioners to the Medical Officer of the Workhouse, and forwarded by them for the information of the Board.

Poor Law Commission Office, Dublin,
August 26th, 1870.

SIR,—The Commissioners for Administering the Laws for the Relief of the Poor in Ireland acknowledge the receipt of your letter of the 12th inst, enclosing an extract from the *Downpatrick Recorder* relative to the proceedings at the Downpatrick Board of Guardians on the Saturdry previous, and requesting the intervention of the Commissioners in a matter that may compromise, in your opinion, the lives of the persons under your care, as the proposal put forward by the Chairman, you state, will render you powerless to deal with your hospital cases as you think their exigencies may require.

In reply, the Commissioners desire to inform you that they infer from your letter that you consider yourself entitled, as Medical Officer of the Workhouse, to take a position independent of the Board of Guardians as to the indulgence of the inmltes in the case of stimulants, such as wine and whiskey, and other luxuries, such as tobacco and snuff.

The quantity of such stimulants consumed in Downpatrick Workhouse under your direction would appear to imply that their use is not entirely limited to the inmates of the sick and lunatic wards, as provided in Artice 19 of the Workhouse rules, and the Commissioners presume that the same remark applies to the use of tobacco and snuff by the inmates generally under your direction.

Thus you appear to have assumed authority to give orders to the Master for supplies of the two articles last mentioned, which authority you do not in fact possess ; and you will probably be held liable by the Auditor for the expense so incurred·

You will find from a careful perusal of the General Regulations for the government of Worknouses, that the Medical Officer is invested with adequate power to provide for the necessary treatment of the sick and lunatic classes, and with the privilege, also, of recommending changes in the diet of the othes inmates, or particular classes thereof, but that the Guardians alone have authority to give effect to such recommendations.

The Medical Officers of Workhouses gênerally have not found it difficult, under these rules, to ensure sufficient liberality at the hands of Boards of Guardians in these matters ; but the very worst way in which a Medical Officer can attempt to secure that object is to assume an authority independent of the Guardians which he does not legally possess. Neither is it right towards the ratepayers and their representatives that such liberality as may properly be conceded in regard to dietaries and stimulants should appear to be the result of the generosity of the Medical Officer in opposition to the views of tho Board of Guardians.

The Commissioners recommend you hereafter to govern your conduct in this respect by a careful compliance with the regulations in force for the government of Workhouses.—By order of the Commissioners,

B. BANKS, Chief Clerk.

LIMERICK UNION—WEDNESDAY.

DR. O'SULLIVAN said he would give the Board an opportunity of discussing the question again, and handed in the following notice of motion :—"I will move, on this day fortnight, that our County and City members be requested to lay the case of Dr. F. T. Porter (late Medical Officer of the Castleconnell Dispensary District) before Parliament, with a view of ascertaining whether "the Commissioners for administering the laws for the relief of

the poor in Ireland," exceed the power vested in them by summarily dismissing by sealed order Dr. Porter from his office without a sworn investigation, or affording him the necessary information to enable him to disprove the authorship of a certain anonymous letter, or letters (the alleged cause of dismissal), and if such arbitrary power had been given to the aforesaid Commissioners by law, that said law may be so altered as to afford the Poor-law Medical Officers of Ireland the same amount of justice granted to the most contemptible criminal, namely, a fair and impartial trial.

THE REGISTER.

The Chairman called the attention of the Board to two children who had been admitted to the hospital on a ticket of Dr. Kavanagh's, but who were deemed unfit cases for such a class of relief, by Dr. Phayer, and were sent into the body of the house. There father was alive but was sick, and he (the Chairman) thought the case one which should be dealt with by the Board as one of the class referred to in late discussions. A resolution had been passed on last board day stating that all cases which could be effectually dealt with at the dispensary should not be sent into the house.

The Master said they were two children who had been in and out of the house for the last two years. They were also occasionally in hospital and only recently discharged.

Mr. Delmege agreed with the chairman. The case was one which should be inquired into—it was one of that class which very much swelled the numbers in the house, and which were much complained of. He proposed the attention of the commissioners be called to the matter.

Dr. O'Sullivan said it appeared according to the Master's statement that the boys were constantly in and out of hospital, and the medical gentleman might have good reason for sending them back to hospital. He believed it would be right to hear what he had to say on the matter.

Mr. Cronin—I think we should have Dr. Kavanagh's explanation. He is one of our ablest and most experienced physicians, and would do nothing, professionally or legally, which he deemed to be incorrect. (Hear, hear). The least courtesy we could show him would be to postpone this matter until he has an opportuity of replying to a communication from us. I therefore propose the matter be communicated to him with that view. (Hear, hear).

Dr. O'Sullivan—And I second it.

Mr. Delmege said the case ought to be inquired futo, but it was right that Dr. Kavanagh's explanation should be heard. However, it appeared to be wrong that the boys were admitted into hospital.

Dr. O'Sullivan—That remains to be seen.

Mr. Browne said that the question for admitting such cases into the house at all would have to be discussed. There was no reason why the sick father should be retained outside and the children sent into the house.

Dr. O'Sullivan asked what evidence had they that the father was in such a state that he could be removed at all.

Mr. Cronin's resolution was then agreed to.

TIPPERARY UNION.

PAYMENT OF LAW COSTS OF VACCINATION PROSECUTIONS.

Mr. DWYER said, as regarded the summonses in vaccination cases, a case came before the Bansha Petty Sessions on the previous day, when Captain Dawson presided, and the professional gentleman engaged for the prosecution applied for 30s. costs

The bench had, however, reduced the amount to 7s. 6d., and 2s. 6d. for the fine and costs of court. It was said at the board that a small fine inflicted in a few cases would be a caution to persons not to infringe the law, in the case to which he referred the child had been vaccinated, but he was not brought for inspection at the end of eight days. The man swore that when the doctor told him to bring the child, after thirteen or fourteen days, he at once did so.

Colonel Purefoy observed that they were only losing time in discussing this matter, for they could not control the magistrates. In future they would not need a solicitor, as Captain Hamilton had said it was not necessary to have one. He thought it was perfectly right that persons who did not comply with the Vaccination Act should be summoned. In consequence of the attention paid to it in some districts there was no small-pox to be found, and if it were properly carried out the disease would be gone entirely.

Captain Dawson was sorry that the poor man at the Bansha sessions had been fined so much, but the magistrates could not act otherwise than they did. He had been sent to several times to bring in his child, but did not do so. Then when he was summoned he engaged an attorney to defend him, and the board had another to meet him.

At the request of Mr. Quillinan, the clerk read the commissioners' letter, stating that the prosecutions could be brought by the clerk or relieving officers, and not by the board as a corporate body.

CLONMEL UNION.

On the question of the Resignation of Dr. Prossor.—A discussion then arose as to whether the board had power to accept the resignation at all, and whether it should not first have been forwarded to the dispensary committee.

Mr. Shee said he thought it would be their duty to advertise, and proceed to elect a successor.

Mr. Davis read from the regulations that the power lay in the hands of the committee, and

Mr. Riall read from the Act of Parliament, showing that the guardians could elect.

Alderman Hackett suggested they should notify the resignation to the commissioners, and its acceptance by the board, and then wait directions from them as to the course to be followed.

Mr. Cantwell thought they could not accept the resignation before the committee.

The Chairman said it had been accepted, and signed by him.

It was finally agreed to direct the clerk to inform the secretary of the committee of the resignation, in order that he might take such measures as are necessary for the election of a successor to Dr. Prossor.

Mr. Thomas Cantwell then gave notice of motion that, in consequence of the resignation of Dr. Prossor, through ill-health, he would move that he get the usual superannuation allowance in accordance with the provisions of the Act.

Correspondence.

TO THE MEMBERS OF THE IRISH MEDICAL ASSOCIATION.

GENTLEMEN,—It has been long felt by myself and many of the profession, who have given their attention to the subject, that, instead of coming before the country as it were "in forma pauperis," when seeking by Act of Parliament for Superannuation Allowance, we should, in the first instance, have endeavoured to prove to the world that we were able and willing to make an independent effort for ourselves. The ancient's inculcated a wise principle of self-reliance in the adage, "The Gods help those who help themselves," and I am convinced, that, had we in the *Strength of Union* given evidence of that self-reliance, we should have carried the opinion of the country with us, and with it, a substantial recognition of our services, instead of being, as we were the long baffled and disappointed suers for the sparing and hard-handed bounty at length *wrung* from unwilling rate-payers; I ought not to use the word *wrung*, for by the careful omission of the compulsory clause, they have secured for themselves the power of denying the *pittance* authorized by law to those, who, however strong and just their claims may be, are not fortunate enough to possess sufficient local influence for commanding a majority among guardians, who, apart from such influence, will assuredly

weigh well the value of an additional farthing in the poundage-rate as against the just claims of their worn out officer.

They have the further power of ignoring any length of service, as a claim for Superannuation, if such service has been in *any Union* save the one where the claim is preferred, thus a man may have spent his professional life in the Poor-law Medical Service, and yet have been only just long enough in any one union to be looked upon as "*Nobody's Child.*" I endeavoured at a meeting of the Association last year to convince my medical brethren, that the Superannuation likely to be obtained by *the Act* then sought for, would be paltry and insufficient, even if we were able to carry a Compulsory Clause, but as a mere Permissive Bill it could prove nothing but a delusion and a snare ; I then suggested that the better course would be, to seek for the legalised establishment of a *Poor-law Medical Officer's Retiring Fund*, on the basis, and as far as possible on the plan of the Constabulary Fund : endeavouring at the same time to obtain, if possible, an Annual Parliamentary Grant, as an auxiliary aid to our self created Fund, equal to one third ? of the sum annually stopped from our salaries as contribution to the Fund. I was met by the objections, that the Bill was then too far advanced to be changed or withdrawn, that it was better to get in (through the Bill) the fine end of the wedge in the hope of driving it further at a future time, and that the taking of such a course in no wise prevented us from establishing such a Fund, which they, the objectors, thought highly desireable. Such were the opinions expressed by those gentlemen who had been exerting themselves for the passing of the Bill, and notably, of our worthy and esteemed President, Dr. M'Namara. Under those circumstances, and in the face of such an opposition I had to *subside* for the time, though unconvinced, but I think now, when it has been proved how *very fine* and *very weak* the point of our wedge is, how unlikely to be driven for any reasonable depth into the block opposed to us, how very inadequate the retiring allowance, even on the full legalized scale of the act, would be, either as a reward for long service, or as a means for maintaining an educated man through the years of his declining life, even if it were to be obtained as a certainty, through length of service or loss of health, how much less so, when the obtaining of it, being but permissive, is most uncertain.

The time has come when the Poor-law Medical Officers, should, as a united body, make an effort, if they would secure for themselves and those dependant on them, the means of a decent existence when the time for the active exercise of their profession has passed by. I select this time for bringing the subject prominently before the profession, knowing that the establishment of a Co-operative Fund for the benefit of Poor-law Medical Officer's Widows, is in contemplation, and will soon be brought under consideration. Now, nothing can be more laudable than the establishment of such a fund, but, as many of us are not married, and some of us never will be, such a scheme must of necessity be limited in its appeal for support, to those who will join it voluntarily, as Benedicts, actual or prospective, or such as sympathize strongly with those who are in that happy state. Feeling therefore, that a Superannuation Fund established on the Constabulary Fund basis, and to which all *must* contribute, would be a positive success ; and believing, that a Widow's Fund, by itself, and unconnected with the Superannuation Fund, would be much less likely to succeed, and *possibly* result in failure, I would strongly recommend, that both should go hand in hand, that the whole body of the Poor-law Medical Service be incorporated under the Benevolent Society's Act, having the style and title of the Poor-law Medical Officers' "Retiring Superannuation Fund and Widows Annuity Society," that the accounts of the Superannuation Fund, and those of the Widows' Fund be kept separately, that the contribution to the first shall embrace all Poor-law Medical Officers ; shall be compulsory, and by deduction from pay, as in the constabulary, while membership in the "Widows' Fund Branch," shall be voluntary, but that the contributions thereto shall be paid by members in a similar way as that to the Retiring Fund, that is. by deduction from pay as in the present Constabulary Offices Widows' Fund." I am not aware whether there be any legal difficulty in the way of conjoining the two Funds, under one and the same Co-operative Society, inasmuch as the working of them would be dissimilar : if there be, and that the difficulty be insurmountable, let us still have both, though separate, but I consider the subject of such paramount importance to the profession, as to be well worthy of our most serious consideration, and as well worthy any preliminary expenses for having the advice of counsel, the services of an actuary, and for the advising on, and consideration of, the subject, between a well selected committee of our profession, and those gentlemen who have had experience in, and are conservant with, the working of the constabulary and other similar Funds ? to such preliminary expenses I as an humble individual, will be most happy to contribute. I annex a crude sketch of rules for both branches of the Society, based upon the Constabulary system, but necessarily differing in some respects. I only mean them for an outline to be altered and filled up by the working committee, who may (should our plans prosper), have the organizing of the scheme. With every apology for this long and, in many respects imperfect, letter, and in the hope that it will draw the attention of abler heads and abler pens to a subject of such importance.

I have the honour to be gentlemen, your obedient servant,

R. M. TAGERT.

Carrickmacross, August 25th, 1870.

Sketch draft of Rules for "The Poor-law Medical Officers Retiring Superannuation Fund and Widows' Annuity Society."

No. 1.

Rules specially applicable to the Superannuation Fund.

1. That the Society be incorporated under the style and title of the Poor-law Medical Officers' Retiring Superannuation Fund and Widows' Annuity Society.
2. That its place of meeting shall for the present be the College of Surgeons, Dublin.
3. That the following persons with others, shall be Trustees of the Funds (*to be filled up*), and shall continue so to be, till removed by a majority of members present at a full meeting.
4. That it be compulsory on all Poor-law Medical Officers from the date of enrollment to pay, by way of deduction from their salaries, quarterly, or as such may be paid to them, 6d. per pound on their gross pay, towards the Retiring Superannuation Fund, this will give an annual income of about £2,000.
5. That in order to create a Fund, and to enable such medical officers, as may wish, to come under the more immediate benefit of the Society's Funds, it will be optional for such members to pay a sum on enrolment equal to years' contribution to the Fund, with interest thereon at five per cent.
6. That with the exceptional benefit to be secured to members by the optional payment under the foregoing rule, the amount of which benefit is to be settled by Committee, no member can derive any benefit who has not been years a contributor to the Fund.
7. That a medical officer of thirty years service, and over sixty years of age, may retire on full pay ? provided his contributions to the Fund, with compound interest thereon at five per cent, have amounted to the sum of.——
8. That a Poor-law Medical Officer of less than thirty years' service, voluntarily retiring from the Poor-law Medical Service, may either receive such amount of compensation, or annuity, as the Committee may deem fit, according to his length of service, or he may have the option of continuing a member for the residue of the thirty years by payment of his contributions as hitherto.
9. That dismissal from the Poor-law Medical Service may void membership, and be a bar to the receiving of any benefit from the Fund, subject nevertheless to the operation of the following rule.
10. That any member who may have been dismissed the service, or compelled to resign, by the Poor-law Commissioners can bring his case before a full meeting of the members, and should two-thirds of the members present and voting, find, after due hearing and consideration of the case, that the circumstances did not warrant his dismissal, the application of Rule 9 be remitted in his case, so far as the meeting may decide.
11. That all contributions to the Fund shall be paid in to bank to credit of the Trustees, who shall invest them for the benefit of the Society.
12. That voluntary gifts, donations, or subscriptions, in aid of this Fund, be received and duly placed to the credit of the Trustees, for the benefit of the Society.
13. That a Committee of Management be appointed, also a paid Secretary and Auditor.

No 2.

Rules specially applicable to the Widows Fund Branch of the Society.

1. That it be constituted and named "The Widows' Fund Branch of the Poor-law Medical Officers Superannuation Fund and Widow's Annuity Society," holding its meetings at the same place.
2. That its object be, to create a Fund, from which annuities will be paid to the widows of such Poor-law Medical Officers as shall have been members, and contributors, at the period of their death.
3. That membership in the Widow's Branch shall be voluntary, but while it is specially calculated for the benefit of married officers, the unmarried are eligible for membership on paying one-half the entry and contributions so long as they remain single.
4. That the rate of contribution shall be four-pence in the pound on their pay for each married member, to be paid in a similar manner as that to the Superannuation Fund.
5. That in order to create a starting Fund each member on admission shall pay as an entry fee, a sum equal to the amount of one years contribution (or an average sum of).
6. That the following gentlemen, with others, shall be Trustees to the Fund, and shall continue so to be, until removed by vote of a majority of members present, and voting at a full meeting.
7. That monies and contributions due to the Society Branch shall be lodged in bank to credit of the Trustees, who shall invest them for the benefit of the Society.
8. That voluntary gifts, donations, and subscriptions, may be received and duly lodged to the credit of the Trustees, and invested by them for the benefit of the Society in the same way as ordinary contributions.
9. That in consideration of the contributions paid into the Funds of the Society by members, the widows of such members shall be entitled to receive an annuity of £40, subject to revision from time to time by vote of a general meeting, and upon the calculation of an actuary. Such annuity to cease in the event of the widow contracting another marriage.
10. That should the wife of a member die before her husband, the amount which should have been paid to the widow, shall be paid in due proportion for the benefit of the orphan children, until the youngest attains the age of eighteen.
11. That medical officers retain the rights of membership, and all benefits dependant thereon, notwithstanding their retirement from the Poor-law Medical Service, on condition of their continuing to pay regularly the same amount of contribution as hitherto.
12. That any married Poor-law Medical Officers who shall neglect to avail himself of the opportunity of membership for six months from enrolment of the Society, can only join the Society afterwards by payment of a sum equal to the contributions he should have paid from the time he was first entitled to join the Society as a married man, together with double entry fee.
13. That all members on admission shall sign the deed of settlement, and any other covenants binding them to conform to the Society's Rules.
14. That a Committee of Management be appointed, also a Secretary and Auditor, and that separate accounts shall be kept for each member.

TO THE EDITOR OF THE IRISH MEDICAL ASSOCIATION JOURNAL.

Sir,—Your account of the proceedings at Castleconnell, co. Limerick, are calculated to awaken unpleasant reflections in the minds of Poor-law Medical Officers. If the Poor-law Commissioners can dismiss an officer on a charge preferred by an individual, or a clique, without a fair trial by sworn investigation, after the accused has demanded such, thereby clearly raising the question of his guilt or innocence, it surely looks *rather too* arbitrary in days when even-handed justice is the professed rule wherever the British flag waves and British law bears sway. Even the best conducted officer could not feel secure for a week if such high handed practice should or could be carried out. Because there are generally two parties, at least, to be conciliated in every Board, or Committee, and the doctor will find it hard, or impossible, to keep both on his side. Besides this, there is an evident antagonism between the interests of the poor on the one hand, and of the rate-payers (represented by the committee) on the other; and if the doctor insists on the former getting their dues, he treads on the corns of the latter, and is often discountenanced and persecuted.

The visits of inspectors once in one, three, or five years, useful as far as they go, seem of little use in correcting these evils, and the Commissioners (with great respect be it said) seem to know nothing about them. So long as matters go on smoothly, and the doctor can manage to conciliate his governors, so as to avoid complaints, he may do pretty much as he pleases, that is if he has a conscience or anything of that sort he will try to do his duty to the poor; but, if not, ———. But if a complaint be made by a committee man, or a guardian, woe to the unlucky doctor who has *managed so awkwardly* as to come into collision with one of these powerful potentates. However frivolous the charge, it must be fully met and answered, although it cost quires of writing (as you know a fool may start an objection or insinuate a complaint which a wise man will find it hard to answer), otherwise comes the sworn investigation with all its disagreeable concomitants, or it may be, as in this case, dismissal by sealed order. It is no wonder the medical officer (although the working bee of the system, and the man who knows most about it) is afraid to say or do anything which might give offence to one of those who can work him so much trouble at so little cost to themselves, and in whose hands is placed—not wisely—the regulation of his salary.

It is some little credit and comfort that among Dr. Porters's committee, one has been found to express himself in a manner which embodies the idea of perfect justice. Mr. Tinsley said—"I neither know, nor care for, Dr. Porter, but by all means let him have a fair trial," or words to that effect. That is spoken like a man of honour. Would there were many Mr. Tinsleys on Dispensary Committees! We should not then have the hole and corner work so much in favour in some quarters.

I am, yours, &c.,

"M. O. OF 18 YEARS' STANDING."

MONETARY QUALIFICATIONS FOR DISPENSARIES.

On the justice of the course which a persecuting clique have adopted towards Dr. Porter, of Castle Connell, and which the Poor-law Commissioners have considered themselves justified in countenancing and abetting, we have spoken freely in another part of this issue. We think it proper, however, to observe that the *Limerick Reporter* has put forth, in several successive publications, an argument in Dr. Porter's favour, which we think requires repudiation on the behalf of the Profession. It is stated that Dr. Porter paid the widow of the late Dr. Bomford £200 on assuming the appointment.

We venture to remark that this seems to us to be a reason which rather goes to palliate the act of the Commissioners in dismissing the medical officer. It would be a precedent destructive of the interests of the poor and the just claims of Poor-law Medical men, if such a taxation of the incoming officer were held in any respect to entitle him to special consideration, or to give him any lien whatever on the appointment. If his duties were neglected, or his official position infringed in any respect, the dismissal of Dr. Porter, or any other medical officer, would be perfectly proper; and as to the hardship he would suffer in losing his money, we should be disposed to say, serve him right!

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

PROFESSOR TYNDALL ON THE SCIENTIFIC USE OF THE IMAGINATION.

PROF. TYNDALL lectured on Friday evening upon the above subject in the Philharmonic Hall at Liverpool; it was one of the most important evenings during the whole of British Association meetings. Prof. Tyndall, upon coming forward, was greeted with loud cheers. He began by detailing the circumstances under which the lecture had been composed, and proceeded to give instances of the use that scientific men had already made of the power of imagination. In the phenomena of sound they travelled a very little way from downright sensible experience; yet still the imagination was to some extent exercised. The bodily eye, for example, could not see the condensations and rarefactions of the waves of sound. They were constructed in thought, and their existence as firmly believed in as that of the air itself. But their experience had to be carried into a new region, where a new use was to be made of it. Having mastered the cause and mechanism of sound, it was desired to know the cause and mechanism of light. The lecturer proceeded to show how, be the force of imagination and reason combined, the mysteries connected with the phenomena of light may be penetrated. He showed that in the atmosphere there are particles which defy both the microscope and the balance, which do not darken the air, and which exist, nevertheless, in multitudes sufficient to reduce to insignificance the Israelitish hyberbole regarding the sands upon the sea-shore. It could not be too distinctly borne in mind that between the microscopic limit and the true molecular limit there was room for infinite permutations and combinations. It was in this region that the poles of the atoms were arranged, that tendency was given to their powers, so that when these poles and powers had free action and proper stimulus in a suitable environment, they determined first the germ, and afterwards the complete organism. This first marshalling of the atoms, on which all subsequent action depended, baffled a keener power than that of the microscope. At all events, it was plain that beyond the present outposts of microscopic inquiry lay an immense field for the exercise of the imagination.

Alluding to the primordial germ theory which Mr. Darwin placed at the root of life in his "Origin of Species," he said the human imagination would infallibly look behind the germ and inquire into the history of its genesis. From the examination of the solar system, Kant and Laplace, came to the conclusion, that its various bodies once formed part of the same undislocated mass; in our day this hypothesis had received the independent countenance of spectrum analysis, which proved the same substance to be common to the earth and sun. Life could hardly have been present on the earth, how then did it come there. Two views offered themselves. Life was present potentially in matter when in the nebulous form, and was unfolded from it by the way of natural development; or it was a principal inserted into matter at a later date. After paying a passing compliment to the readiness of the clergy to receive and argue these theories, in which he said that the greatest cowards of the present day were not to be found among the clergy, but within the pale of science itself, Prof. Tyndall proceeded to observe that there were the strongest grounds for believing that during a certain period of its history the earth was not, nor was it fit to be, the theatre of life. Whether this was ever the nebulous period, or merely a molton period, did not much matter, and if he reverted to the nebulous condition, it was because the probabilities were really on its side. The question was this—did creative energy pause until the nebulous matter had condensed, until the earth had been detached, until the solar fire had so far withdrawn from the earth's vicinity as to permit a crust to gather round the planet? Did it wait until the air was isolated, until the seas were formed, until evaporation, condensation, and the descent of rain had begun, until the eroding forces of the atmosphere had weathered and decomposed the molten rocks so as to form soils, until the sun's rays had become so tempered by distance and by waste as to be chemically fit for the decompositions necessary to vegetable life? Having waited through these Æons until the proper conditions had set in, did he send the fiat forth, "Let life be!" These questions defined a hypothesis not without its difficulties; but they might rest secure in the belief that it could never be stormed and that it was sure if it yielded at all to yield to a prolonged siege. The process must be slow and secular which

commended the rival hypothesis of natural evolution to the public mind. For what were the core and essence of this hypothesis? Strip it naked, and we stood face to face with the notion that not alone the more ignoble forms of animalcular or animal life, not alone the nobler forms of the horse and lion, not only the exquisite and wonderful mechanism of the human body, but that the human mind itself—emotion, intellect, will, and all their phenomena—were once latent in a fiery cloud. Surely, the mere statement of such a notion was more than a refutation. But the hypothesis would probably go even further than this. Many who hold it would probably assent to the position that at the present moment all our philosophy, all our poetry, all our science, and all our art—Plato, Shakespeare, Newton, and Raphael—are potential in the fires of the sun. We longed to learn something of our origin. If the evolution hypothesis were correct, even this unsatisfied yearning must have come to us across the ages which separated the unconscious primæval mist from the consciousness of to-day. Surely these notions represented an absurdity too monstrous to be entertained by any sane mind. Why were these notions absurd, and why should sanity reject them? The law of relativity which played so important a part might find its application here. These evolution notions were absurd, monstrous, and fit only for the intellectual gibbet in relation to the ideas concerning matter which were drilled into us when young. Spirit and matter had ever been presented to us in the modest contrast,—the one as all-noble, the other as all-vile. But was this correct? Did it represent what our mightiest spiritual teacher would call the eternal fact of the universe? Supposing instead of having the foregoing antithesis of spirit and matter we had been taught to regard them as equally worthy and equally wonderful; to consider them in fact as two opposite faces of the self-same mystery. Was it not probable that our repugnance to the idea of primæval union between spirit and matter might be considerably abated? Without this total revolution the evolution hypothesis must stand condemned, but in many profoundly thoughtful minds such a revolution had already taken place. In substance, if not in word, their position as regarded spirit and matter was "What God hath joined together, let not man put asunder." He had thus led them to the outer rim of speculative science, for beyond the nebula scientific thought had never ventured hitherto; and he had tried to state that which ought in fairness to be outspoken. This evolution hypothesis was not to be flouted away contemptuously, nor to be denounced as wicked; and, instead of fearing the hypothesis, we should seek to steady ourselves in its presence upon our faith in the ultimate triumph of truth.

Its existence as a hypothesis in the mind was, we might believe him, quite compatible with the simultaneous existence of all those virtues to which the term Christian had been applied. For, granting the nebula and its potential life, there still remained to baffle and bewilder the question whence came they? The advocates regarded the nebula hypothesis as probable, and, in the utter absence of any evidence to prove the act illegal, they extended the method of nature from the present into the past. They accepted as probable the unbroken sequence of development from the nebula to the present time. They had as little fellowship with the atheist who said there was no God, as with the atheist who professed to know the mind of God. "Two things," said Immanuel Kant, "fill me with awe—the starry heavens and the sense of moral responsibility in man." And in his hours of health and strength and sanity, when the stroke of action has set in, the scientific investigator finds himself overshadowed by the same awe. Breaking contact with the hampering details of earth, it associates him with a power which gives fulness and tone to the existence, but which he can neither analyse nor comprehend.

As one of the local papers said the Professor ended his theme as if thinking aloud. He ceased, and the spell which had bound his hearers was broken, and an outburst of applause followed loud and long.

CHEMICAL SECTION.

This section was under the presidency of Professor H. E. Roscoe, B.A., Ph.D., F.R.S., F.C.S., who, in his address reviewed the progress of chemical science since the last meeting of the association in Exeter. The president pointed out that in spite of the numerous and important brilliant discoveries of which every year has to boast, we are really but very imperfectly acquainted with the fundamental laws which regulate chemical actions, and that our knowledge of the ultimate constitution of matter upon which those laws were based, was but of the most elementary nature. In proof of this he referred to the difference now existing among chemists as to the existence of atoms, some regarding it as the very life of chemistry; while others, while admitting that the theory explains certain chemical facts, are reluctant to accept it as true. Sir Wm. Thompson had not only come to the conclusion that matter is not infinitely divisible (and therefore that atoms exist), but had attempted to give an idea of their size,—"the mean distance between the centres of contiguous molecules is less than the hundred-millionth, and greater than the two-thousand millionth, of a centimetre." Professor Roscoe said he considered that the results of the mechanical theory of gases—which presupposed molecules—rendered the existence of indivisible particles more than likely. In this connection he referred to the death of Graham and his researches in molecular chemistry. The next topic was Dr. Andrew's (of Belfast) experiments with gases, which have upset the theory that the three states of matter, solid, liquid, and gaseous, were distinct, and dependent upon pressure or temperature. He had proved that a large number of, and probably all, easily condensible gases possess a critical point of temperature at and above which no increase of pressure can be made to effect a change into the liquid state, the body remaining as a homogeneous fluid, whilst below this critical temperature certain increase of pressure always effects a separation into two layers of liquid and gaseous matter. As examples of the power of modern methods of research, the president referred to the researches in solar physics of Frankland, Lockyer, and Zollner, the latter chemist having arrived at the probable absolute temperature of the sun's atmosphere as well as that of the internal molten mass. These results, said Professor Roscoe, are so interesting and remarkable as being arrived at by the combination of recent spectroscopic observation with high mathematical analysis, that I may perhaps be permitted shortly to state them. Starting from the eruptive nature of a certain class of solar protuberances, Zollner thinks that the extraordinary rapidity with which these red flames shoot forth proves that the hydrogen of which they are mainly composed must have burst out from under great pressure; and if so, the hydrogen must have been confined by a zone or layer of liquid from which it breaks loose. Assuming the existence of such a layer of incandescent liquid, then applying to the problem the principles and methods of the mechanical theory of gases, and placing in his formulæ the data of pressure and rate of motion as observed by Lockyer on the sun's surface, Zollner arrives at the conclusion that the difference of pressure needed to produce an explosion capable of projecting a prominence to the height of 3·0 minutes above the sun's surface, a height not unfrequently noticed, is 4,070,000 atmospheres. This enormous pressure is attained at a depth of 139 geographical miles under the sun's surface, or at that of 1-658th part of the sun's semi-diameter. In order to produce this gigantic pressure the difference in temperature between the inclosed hydrogen and that existing in the solar atmosphere amounts to 74,910 deg. Cent. In a similar way Zollner calculates the approximate absolute temperature of the sun's atmosphere, which he finds to be 27,700 deg. Cent.—a temperature about eight times as high as that given by Bunsen for the oxhydrogen flame, and one at which iron must exist in a permanently gaseous form. Among the more purely chemical subjects to which the president went on to refer were: the experiments of Julius Thompson, of Copenhagen, as to the heat of chemical combinations; the invention of a new galvanic battery by Bunsen, the electro-motive force of which to the most powerful battery now known is as 25 to 18; to the discovery in organic chemistry of a missing link among the oxy-sulphur acids—hydro-sulphurous acid H 2 So 2; to the metallic vandates which had been found to have a corresponding order of salts to the phosphates. In organic chemistry he referred at some length to the investigations on mellitic acid. The discovery of the sedative properties of chloral hydrate marked an era in medical chemistry second only to the discovery of the anæsthetic properties of chloroform. The chemistry of colouring matters had received an enormous impetus in the practical working of the brilliant discovery of the production of artificial alizarine, the colouring matter of madder. This discovery differs from all former results, inasmuch as it has reference to the artificial production of a natural vegetable colouring substance in enormous demand. During the past year much progress has been made in the practical working of the processes by which the colouring matter is obtained. The president referred in the last place to the utilisation of waste products in manufacture, and enu-

merated three valuable processes recently introduced into our most important chemical manufacture—that of alkali, Dr. Mori's method of recovering sulphur from the vat waste, Weldon's process for the recovery of black oxide of manganese, and Mr. Deacon's mode of producing chlorine from hydrochloric acid without the aid of manganese.

SECTION FOR BIOLOGY.

Professor Rolleston presided in this section, which was divided into three departments, that of zoology and botany, that of anatomy and physiology, and that of ethnology and anthropology.

Professor Rolleston, in his opening address, drew attention to the importance in the interests of science of trained students observing natural history, and he especially urged the necessity of local observations. He expressed a wish that there was in every district a Gilbert White to write its natural history, as White wrote that of Selborne. He urged the desirableness of establishing "field clubs," and expressed an opinion that it was to the development of provincial museums that we must look in the future for the extension of intellectual pursuits throughout the land. From these museums, while the chief object of them should be to obtain collections from the districts in which they were placed, he would not exclude foreign specimens, but he insisted upon the proper classifying and cataloguing of all specimens. While not depreciating scientific instruction as a means of training the mind, he cautioned scientific students against the neglect of literary pursuits. Proceeding to review the subjects which will be considered in the section, Professor Rolleston said that one of the most important of these subjects, that of spontaneous generation, touched upon certain susceptibilities lying outside the realm of science. He, however, reminded his audience that in the sectional discussions they had only to do with the scientific arguments bearing upon the questions; and he hoped that the committee would be supported by the members in excluding all extraneous considerations. Truth being one, all roads leading to it would assuredly converge sooner or later; their business was to see that the road with which they were particularly concerned was properly laid out. In this view he was glad to be able to fortify himself by the dictum of Archbishop Whately:—"The possessor of real faith will be fully convinced that whatever suppressed physical fact appears to militate against his religion will be proved to be natural, or else be reconcilable with his religion." The archbishop further said that if he were to found a church he would make it one of his articles that it should not be lawful to bring forward Scripture or religious considerations to disprove scientific theory, which only should be applied in the region of morals. He (the lecturer) wished that Archbishop Whately had founded such a church. (Hear, hear, and cheers.) This, and other testimonies which he quoted, were most important, but he could not forbear to point out what might seem to be a want even in the dicta of such men. They had allotted the privilege of error of teaching to the utterances of only one of the parties concerned; they had forgotten the woe which religious men and theologians had brought upon the world because of the offences which they, with ill-considered zeal, had created. They had left something unsaid which might be summed up in the homely caution that "there may be faults on both sides." He trusted that discussion upon the scientific aspects of these great questions would not be restrained, it being kept in mind that mutual forbearance might slacken progress as well as excite mutual jealousies. In conclusion, he expressed a hope that the association would adopt some means to carry out the suggestions he had made in the opening of his address. He would be more than satisfied, and all his objects would be fully accomplished, if only as much money could be obtained for these purposes as was lost to the people every year through suffering and death, occasioned directly by ignorance of scientific facts and principles relating to sanitary arrangements alone.

THE SOCIAL SCIENCE CONGRESS FOR 1870.

The annual congress of the National Association for the Promotion of Social Science was opened last Wednesday at Newcastle-upon-Tyne, when the inaugural address was delivered by the Duke of Northumberland, the president of the year.

His Grace, who was received with cheers, proceeded, after some opening remarks, to discourse with much eloquence on the suitability of Newcastle for the meeting of a congress assembled to discuss important problems relating to the improvement and welfare of the human race.

He then proceeded to review a number of social or socio-political topics of great general interest. The pressure on our space prevents us giving more than a few extracts from the duke's address, selected with a view to their suitability to our columns.

EDUCATION.

With regard to the instruction of youth, I think we may congratulate ourselves on the passing of a measure calculated to reconcile, as far as they can be reconciled, the advocates of the rival systems the merits of which have been so warmly contended for in the late discussions upon this much-debated matter. Yet the measure now become law must be considered rather as a preliminary preparation for the fulfilment of a scheme than a scheme itself. It has not proscribed religious, though it has dogmatic, teaching in the schools hereafter to be created by rating, and the country must be congratulated on having brought to bear the practical good sense of the nation on this all important point at a moment when the authors of the measure might have been induced to yield to pressure in the opposite direction. Holding the conviction that education in its proper sense is the fostering and directing the growth of the spiritual as well as intellectual part of man's nature (though I am somewhat loath to repeat what many will consider an universally acknowledged truism), I esteem it a miserable mistake to look on instruction, which is only conveying information, as satisfying the real requisites of society in this matter, which ought to be the fitting of the man, not only for the discharge of the duties of the station allotted to him here below, but for the far higher one he ought to aspire to hereafter—the education of the whole man, not merely the cultivation of the intellect.

Religious or Secular Education.—I must express my regret that those who were entrusted with the management of the Education Bill were induced to consent to the clause forbidding the teaching of any formulæ in the schools maintained by rates. It is not so much on account of my attachment to the Church of England that I lament it, as on account of its ignoring that which I hold to be a necessity with most minds—the adoption of some concrete form or creed by which religion can be engraved on the memory, if not on the heart. Abstract principles find no holding ground in ordinary intellects. Most men are not thinkers, and never can be, but an idea may be impressed on their minds and form a basis of action, upon which they may be quite unable to reason. To supply this groundwork is the office of definite religious formulæ. I am sufficiently narrow-minded to be convinced that there is not a sect which really believes in Christ whose doctrines would not form a better foundation for a man's life than a mere set of philosophic axioms, which, asserting no hold over the heart, impress themselves but very feebly on the ordinary understanding. The Sermon on the Mount, taught by mere human authority in the same way as the philosophy of Greece, would, I doubt not, have as little influence over a man's conduct as that exercised by the wisdom of the Athenian sages or the maxims of Confucius. That philosophy has failed to essentially ameliorate or elevate mankind, whilst the Christian religion, in spite of, and even perhaps through, the very antagonisms which have sprung up in the midst of the Christian Church, has had a power for good, to which, leaving out other proofs of a more general and cogent description, I hope our meeting here to-day is a true, though perhaps a feeble testimony.

Compulsion.—The question of compulsory education, properly so called, can hardly be said to have received a solution anywhere, and I may well hesitate to express an opinion upon it. Abroad its success has been extremely doubtful. In America it seems, to judge from their own statistics as well as from the authorities, both native and foreign, who have written on the subject, that apart from the character of the education given, the system can be but partially carried into effect from the difficulty of enforcing it on those to whom it is applicable; whilst, as might be expected, greater success has attended the more regular and despotic pressure of the German governments. In the crowded state of the population of this country, the difficulty of providing the means of subsistence is so great, and, with regret it must be confessed, the ignoring of the advantages of instruction so common, that

compulsory measures will be far more severely felt; and the more so from the entire freedom hitherto enjoyed, and in this direction too often misused by the people at large. I fear that, from the contemplation of society in America, one cannot conclude that the system of education in operation there has produced the beneficial effects which we hope to see result from our efforts. Making every allowance for the crowds of foreigners which, hardly landed from Europe, find themselves on a level with the native born, we cannot but mark the inclination to maintain the exploded errors of old European societies, and observe with sadness the same profound ignorance of the truths of political economy, the same ruinous inclination to consider capital as the enemy of labour, and, alas! the same propensity to violence and outrage which prevails so lamentably in certain sections of our own working classes, whilst neither morality nor sobriety appear to have been promoted in that proportion which the fond hopes of the founders of their educational system had promised to their posterity.

The Scotch Plan.—The plan pursued in the sister kingdom of Scotland presents in many respects a favourable contrast. It is rendered almost compulsory by universal usage and a deep conviction of its benefits, the best, indeed the only mode, in which one would, as a general rule, desire to see education made compulsory; and yet, deeply rooted as it is in the feelings of the Scotch people, and quite as successful as any other that can be instanced, it is a question whether its tendency has been to foster a spirit of religious charity and goodwill amongst the different classes of society, content with existing institutions, sobriety, and morality, to the same extent as it has engendered that spirit of critical disquisition and inquiry, as well as of self-reliance, energy, and frugality which are the peculiar characteristics of that people.

COMPETITIVE EXAMINATIONS.

The competitive examination, now the only mode by which entrance is to be obtained through the straight and narrow gate which admits to government employment, has two great disadvantages—firstly, that of being in itself a very unfair and unjust test as regards the candidate himself; and, secondly, of affording no proof of his real fitness for such employment. With respect to the first, it must be obvious that the candidate's success must depend quite as much on the attainments of his fellow competitors as on his own; it is complicated by the great variations unfairly introduced year by year into the standard by which those attainments are estimated, whilst there is on the part of the examiners a natural and ever-increasing propensity to raise their requirements. The result is a practice has been introduced too well known by the name of cramming—that is, gorging the memory with knowledge which the mind is not required or enabled to digest, so that success becomes a matter of memory rather than of intellectual power. As to the second point, the candidate who is successful too often brings to the service of government a mind and body exhausted by premature exertion, to whom the drudgery of the petty duties of official routine is disgusting, the more so as he is conscious of being fitted by superior attainments, if not by superior intellect, for far higher posts and occupations. These duties are, therefore, performed grudgingly and without spirit, and relinquished for any employment holding out brighter prospects than the niggardly pay doled out by the parsimony of the Government to its servants. It is not less doubtful whether this measure has been successful in producing the changes which it was supposed would result from it. The humble talent which it was one of the alleged objects of those who introduced the practice to bring forward for the higher offices, finds itself, as a general rule, placed at great disadvantage in the race with the richer class of competitors, to whom money must, as it does in other things, smooth and facilitate the road to the attainments required. May we not conclude that, after all, a less rigid rule would in reality be advantageous to all parties? Without advocating the practice of our transatlantic brethren, where any and every one, from the rail-splitter to the millionaire, may pretend to fill any office in the State, can it be desirable that Government employment in this country should be closed to every man who cannot, before he arrives at manhood, pass an examination which the highest medical authorities declare to be generally injurious to the body, and many well qualified to decide, have declared to be almost as detrimental to the mind and intellect. These are not solely my own opinions, but in my intercourse with men who have administered every department in the State, many of them foremost in the advancement of what are usually called Liberal ideas, they have expressed to me in private their concurrence in the views I now state, though they are too conscious of the hold that the present system has on the public mind to be willing to run counter to it. Possibly, however, and I trust it may be so, my words may find an echo in the breasts of some of those around me, whose minds refuse to bow before the tyranny of the popular creed of the day, or to be cramped by the teaching of a narrow and unpractical philosophy, which holds knowledge, however deep and solid, insignificant when weighed against multifarious attainment, however superficial, or versatility of genius, however useless for practical purposes. I will not dwell on the cruelty to the candidates rejected in competition from no fault of their own, and yet on whom the disappointment of failure and a certain stigma must rest, than which there are few things harder for the young to bear, or more injurious to their characters. Speaking in a general sense, it is not by confining minds to distinct channels of occupation, by immuring them within the close limits of particular callings and professions, ignoring all talent unless exercised in a particular groove—thus imitating under another form the long-exploded mistake which permitted no man to practise any trade, or as it was called, mystery, unless he belonged to some guild or association, hermetically sealed to all but those to whom the jealousy of the ruling members from time to time vouchsafed an entrance—that society will make progress in the solution of the great problem of maintaining and increasing the welfare of an ever-growing population. It is rather by giving as free scope as possible to the display of the talents and the exercise of the energies of the individuals composing it, and by removing impediments to the employment of such energies and such talents for the public benefit.

SANITATION.

No expense has been spared in bringing the necessary supplies of pure water to most of our cities and great towns. The difficulty of dealing with it after it has been rendered noxious by the uses to which it is there applied, and its consequent pollution with refuse matter of every description, is principally that of carriage. Some recommend its purification by filtering, which, supposing this effectually done, still leaves the trouble and expense to be incurred of conveying away the solid residue. Others, and I think it the more correct solution of the problem, recommend that the water should continue to convey its burden to sites where it can be allowed to deposit it as a fertilizing agent in the soil, and, whatever the cost in particular localities, this appears, on the whole, the most natural and the least operose of the schemes devised, and by the proof of experience effectual for the object desired. The state of the law with respect to the poisonous products which some manufactories discharge into the sewers, and which thus find their way into waters hitherto uncontaminated, will scarcely be thought sufficiently stringent by those who are exposed to suffer from this unwarrantable proceeding. I trust that the reading of some papers on this subject, which we may hope to hear from those of our members who have examined into this matter on behalf of the government, will demonstrate to all concerned that the prevention of the mischief is alike practicable and generally inexpensive; but at all events, it should be considered by the manufacturer as part of the cost of the processes, and as a first charge on the profits of his manufacture.

EMIGRATION.

The physical evils affecting the condition of the huge masses crowded into the comparatively narrow area of our large towns are hardly less palpable than the moral mischief consequent on this unnatural and unwholesome condition. But these latter, alas! admit of no more physical remedy, Palliatives must, of course, be applied in the shape of improved lodging, greater facilities for cleanliness and ventilation, better supplies of water, and, as far as possible, the enforcement of the provisions against the pollution of the air by smoke; but these are but palliatives which can only be carried into effect by a far more close and diligent system of supervision than is, or perhaps can be, at present exercised. It is a saddening thought that, raise the existing population to whatever pitch of comfort and prosperity you may, that very prosperity only invites the influx of the needier portion of that of the surrounding districts, and when the reverses to which all commercial and manufacturing societies are exposed take place, the new comers do not as a rule return to their original localities, but remain an ever increasing burden of want, wretchedness, and moral debasement on the communities into which they have migrated. What remedy is there? I see none, unless it be

the bridging over the distance, so to speak, between the labouring population of this country and those regions where the demand for labour is greater than the supply, by a regular and systematic plan of emigration, which shall, as far as possible, surround the emigrant on his arrival in another land with the same influences, institutions, and advantages as he leaves in the mother country. I am happy to see that amongst the subjects to be submitted to your attention this is likely to be fully canvassed, and that there are those amongst us who will bring to bear on it the experience of many years of foreign service in a great variety of our colonies. Hitherto government emigration may be said to have been confined almost entirely to the labouring class, and to the protection of that class its attention has been solely directed. No one thinks that it ought to have been less. But it may be a question whether it might not go further, and that by some admixture of emigrants of a higher class great benefit might not be conferred on both. It is generally held that without some capital a man above the rank of a labourer or workman is useless as a colonist. Is it possible to devise some course of special instruction and training by which such persons may be fitted to seek abroad a freer existence than that afforded by the only occupations which are open to them at home, overstocked as the market for their employment, and consequently ill paid as their service, is? But if this idea be held to partake a little of the visionary, no one will be inclined to dispute the advantages emigration offers to every one, whatever may be his antecedents, who seeks a market for the manual labour he cannot dispose of at home.

Original Communications.

A CASE OF RUPTURED UTERUS SUCCESSFULLY TREATED.

By Dr. Scott, of Bagnalstown.

On Thursday, the 28th of July, I was sent for to attend in her confinement a poor woman residing in the neighbourhood of this town. As I happened to be from home at the time, Mr. Borthistle, of the City of Dublin Hospital, who was on a visit at my home, kindly attended. On examining the case he found some symptoms of ruptured uterus, and knowing the woman to be in a dangerous condition, at once despatched a messenger for me. I arrived about four o'clock, p.m., bringing my midwifery instruments with me, and found the patient in bed. She was a thin, spare woman of about forty-five years of age, and the mother of five children. Her previous labours had been natural and of short duration. She always enjoyed good health. Her pains, I was told, set in about six o'clock the evening before, after a row she had with a neighbouring woman, but they were not troublesome until six o'clock in the morning, when there was a good deal of flooding. The waters came away about ten o'clock, and for two hours the pains were very violent. The nurse in attendance stated that she expected the birth of the child every moment as the head was well down on the perinæum. The patient was resting on her knees and elbows, and, during a very violent pain, she suddenly found something break (own words), and she described the rupture as something like the bursting of a bladder, with a rush of water in the lower part of abdomen. Labour pains at once ceased, but a more distressing pain set in about the pit of her stomach, with great tenderness to the touch, and sickness with inclination to vomit. On examining the abdomen externally, I felt the limbs of the child through the thin walls, about two or three inches below the ensiform cartilage; and, on examining per vaginam, I found the head had receded about four inches, which helped to confirm the diagnosis Mr. B. had made, that there was an extensive rupture, and that the child had partly escaped. It was my duty to deliver her immediately, but from circumstances over which I had no control, did not attempt to operate until after eight o'clock—remaining with her all the time. Previous to operating, I gave a full dose of opium with brandy. I had very little trouble in getting on the forceps, but had a deal of pulling before I delivered her of a very large male child, who was, of course, dead. As there was no hæmorrhage, I let the woman rest for about twenty minutes, then introduced my hand to take away the placenta, which I found over the right ileum floating in fluid. On gently pulling the funis, it came away, followed by about a pint of dark grumous blood. While my hand was in the abdomen I could distinctly feel the uterus firmly contracted. After giving her some stimulants with laudanum, I attempted to put on the bandage, but the tenderness of which she all along complained was so great, that she would not allow me to tighten it on her.

My young friend, Mr. B., suggested grain doses of opium, which I gave her every two hours, combined with two grains of the grey powder, and this she continued to take until the gums became quite tender; linseed poultices and stupes being kept applied to the abdomen. Immediately the gums were affected she began to get relief from the pain and tenderness. Her diet consisted of milk, chicken broth, &c., but no more stimulants were allowed, nor were they much needed. What appeared strange there was no lochia, or other discharge, during recovery. The woman is now quite convalescent (August 29th), and able to go about. The cause of the rupture I cannot say; there may have been some thinning at the seat of rupture, which could not resist the strong labour pains.

CLINICAL MEMORANDA.—SUBCUTANEOUS INJECTION OF MORPHIA CASES.

Reported by John Martin, M.D., M.Ch., Assistant-Surgeon to Mayfield Factory Dispensary.

The subcutaneous method of administering morphia has now so firmly established its claims to the favourable consideration of the Profession, that I feel it would be a task, quite superfluous on my part, to say much in its advocacy. No greater boon could have been conferred upon those, whose duty leads them to scenes of pain and anguish, than the power of giving *immediate* ease; and how often is it the lot of those, who in such cases, proper to its use, have called to their aid the hypodermic syringe and morphia solution, to see the agonies subside, even before the operation is concluded, and the worn-out sufferer sink into a quiet sleep. Such are, indeed, moments of happiness to those who love their Profession, for the good it is able to accomplish. In offering the following brief notes of cases, in which the good results obtainable from the hypodermic use of morphia were apparent, I do so merely to record my experiences for the encouragement of others, and as a contribution to the literature of this branch of therapeutics, for I am convinced as time goes on, that the subcutaneous administration of the *active principles* of medicines, will receive a larger and more deserved amount of attention than it does even at the present time.

First Case.—Anne McClelland, æt. thirty. Until about three years previous to commencement of present illness had been a weaver in a cotton factory; since leaving that employment has been a needlewoman. Has at all times been delicate and weak-chested. Health began to show decided symptoms of a break-up about three months previous to the date of present notes, July 10th, 1870, since when preliminary consumption has made rapid progress. During the last two months has suffered terribly from violent headaches, profuse perspirations, obstinate constipation, loss of sleep, wasting and extreme emaciation, and for the last ten days she has been losing her appetite, which up to that time had held good.

Physical examination showed that both lungs were universally and deeply implicated; loud bruits were to be heard over the mitral and aortic valves. There was no enlargement of the area of cardiac dulness. She was

dreadfully harassed with a racking cough, attended by muco-purulent expectoration. She had been over two months unable to stir from her bed, and signs of bedsores were becoming apparent. Altogether, she was in a state of the utmost misery, and death seemed the only possible relief to her sufferings. Opium and morphia failed completely in giving her any rest at night. I then commenced giving her subcutaneously every night one-third of a grain of morphia, first trying what effect it would have upon her with a quarter grain dose. This I continued until August the 17th, 1870, the date of her death, with the following results :—

1. Night sweats stopped ; felt quite cool all night ; immediately after the operation she felt a pleasant glow spread over her whole body, but this subsided after a little.
2. Slept well ; at first was a little thirsty.
3. The harassing cough greatly diminished.
4. Regained strength—being able after eight days to leave the bed, and sit up for a little every day, until about ten days before her death.
5. Appetite returned ; drank plenty of milk, whilst taking other nourishment, such as beef tea, &c.
6. Bowels, previously costive, acted regularly, requiring no medicine to move them.
7. Death came gradually, unattended by much pain or suffering, to the last the morphia giving her a good night's rest.
8. Any omission to give the injection was followed by a relapse.

This was one of the most forcible illustrations of the good effects of morphia given hypodermically. Though no other result but death could be hoped for in her case, yet it served admirably to smooth her path to the grave, giving her ease and comfort when she might have been suffering the most intolerable misery.

(To be continued.)

THE SEWAGE QUESTION.

SPECIAL REPORT.

(Prepared expressly for the MEDICAL PRESS.)

No. V.

THE WORTHING SEWAGE FARM.

THE sewage of Worthing is leased by the local board of the place to a company called the Worthing Land Improvement Society, who have contracted to take the sewage for twenty-one years on the following terms—namely, for the first seven years for nothing, for the second seven years at a rental of £10 per annum, and for the third seven years at an estimated value derived from the previous fourteen years' experience. The local board is under an obligation to deliver it, on the above terms, upon the land of the society, and the society have wisely agreed to take no more of the sewage than they like, and only when they like.

The sewage farm consists of about ninety-six acres, of which about eighty-three are under irrigation, half being pasture land and the rest Italian rye grass.

The soil is a very porous loam to the depth of from two to six feet, under which there is gravel lying upon chalk. The soil is, therefore, admirably suited for irrigation purposes.

The town of Worthing has a resident population of about 7,500, and it is so well drained and sewered that the flow of sewage during the day time is at the rate of 55,000 gallons per hour.

For the sake of economising the steam-engine power of the water-works, the whole of the sewage of the town is brought by gravitation to two sewage tanks or wells about thirty feet deep, adjoining the chalk wells from which the water-supply of the town is obtained, and it is lifted from these tanks by the water-works' engine to a height of about nine feet above the ground, and delivered by means of a wooden trough to the irrigation grounds belonging to the Land Improvement Society. In this manner about four-fifths of the day sewage, but none of the night, is distributed upon the land, which, as usual, is sodden and offensive. The composition of the sewage and of the effluent water was as follows :—

Constituents per gallon.	Raw sewage.	Effluent water.
	Grains.	Grains.
Total solid matter in solution.	30·33	40·67
Chloride of sodium . .	—	—
Organic matter . . .	2·37	1·25
Ammonia	0·235	0·089
Ditto organic . . .	0·075	0·021
Nitrogen as nitrates, &c. .	0·338	0·340
Oxygen required to oxydise	0·323	0·123
Matters in suspension . .	4·38	0·00
Organic matter . . .	0·87	0·00
Mineral ditto . . .	3·51	0·00

It is evident, from these results, that the sewage of Worthing is largely diluted with subsoil water, and that it is of little value for agricultural purposes ; but, diluted as it is, the Land Society do not take one-third of it, the rest being allowed to flow from the tanks into the Teville stream, which carries it into the sea to the eastward of the town. Time will show how far the undertaking of the company is a sanitary success, for the condition of the Teville is still very unsatisfactory, and the proximity of the sewage well to the water-supply well is, at least, suspicious.

As to the commercial profits of the undertaking, we could obtain but little information, but they ought to be considerable, seeing that the sewage is put upon the land and given to the company by the local authoritiy, and that the company can take it only when they choose.

No. VI.

THE SEWAGE MEADOWS AT CARLISLE.

THE population of Carlisle is about 31,000, and the sewage of the town amounts to about 800,000 or 900,000 gallons per day. It flows towards the river Eden by two outfalls, one of which still runs into the bed of the river, and the other is leased to Mr. McDougall, at a nominal rent, for fourteen or twenty-one years. The sewage from this outfall amounts to about 500,000 gallons a day, and it flows by gravitation to a well at Willow-holme, which is at the head of the irrigation fields. It is there treated with a solution of carbolate of lime in the proportion of two gallons of crude carbolic acid and 18 lbs. of lime to the day's sewage. The carbolate of lime runs into the sewage in a graduated stream, and the mixture is lifted by a Gywnn's pump, that is worked by a steam engine of eight-horse power, and discharged into a trough upon a rather high bank which skirts the farm for about half a

mile. From this trough it is distributed upon the land, wherever it is required, by moveable iron gutters, about six feet long and a foot wide, placed end to end. There are about forty of these discharges, and they are changed every twelve or fourteen hours, so that the whole of the land, amounting to about 120 acres, is thus irrigated at least three times a year. The land is entirely grazing land for sheep and cattle, and is let to a butcher of the town at a rental of £8 an acre.

The soil is composed to a considerable depth of disintegrated red sandstone, and is so porous that the sewage quickly disappears from the surface, and is lost in the subsoil water, there being no actual outfall into the river. To obtain, therefore, a sample of the effluent water, we were obliged to dig a hole in the ground and collect the subsoil water. This, together with a sample of the original sewage, was submitted to analysis, with the following results :—

Constituents per gallon.	Raw sewage.	Effluent water.
	Grains.	Grains.
Solid matter in solution . .	30·17	17·67
Chloride of sodium . .	—	—
Organic matter . . .	6·25	2·15
Ammonia	1·920	0·192
Ditto organic . . .	0·120	0·020
Nitrogen as nitrates, &c. .	0·036	0·103
Oxygen required to oxydise	0·780	0·278
Matters in suspension . .	3·62	Not ascertainable.
Organic matter . . .	2·17	
Mineral ditto . . .	1·45	

In this case the sewage was much below the average strength, and was evidently diluted to a large extent with subsoil water before it reached the works; and the effluent water obtained from the hole in the ground was also much diluted with river water, so that the purifying effect of the land upon it was not clearly discoverable.

One fact, however, of great importance was manifest, namely, that the addition of carbolate of lime to the sewage arrested its decomposition, and prevented it from being offensive when distributed over the ground, without injuring vegetation.

The commercial profits of this undertaking are not very clear, although we were informed by Mr. McDougall that he had spent about £1,800 upon the plant, &c., of the farm, and that he paid all the cost of distributing the sewage upon the ground, as well as the rent of it (£4 an acre); and that in return he obtained £8 an acre for the land. This was the condition of things in 1867.

SPECIAL CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENT.

(*Continued.*)

PARIS, SEPTEMBER, 1870.

HAVING now considered the influence of traumatic lesions of the spinal cord on the production of eschars, it remains to pass in review the spontaneous diseases of the spinal cord, and to discover which are those which more peculiarly favour its development. Intra-spinal hæmorrhage and acute central myelitis, both one and the other producing irritation of all the parts of the grey matter in a certain extent of its length, give rise, generally, to the rapid formation of eschars. On the other hand, eschars usually are wanting in cases where the grey substance is not affected in the central parts, but only in the area of the anterior cornuæ, as is seen in infantile paralysis and general spinal palsy. Diseases almost exclusively limited to the whole columns do not produce them. And we may say the same thing with respect to tumours, Pott's disease, or partial myelitis, which, in truth, alter the spinal cord in its whole thickness, but only for a very short part of its length. Thus, eschars in case of spinal disease are the consequence, not of absence of action of the cerebro-spinal centre, but of irritation of some of its parts.

Disturbance of the nutrition of parts consecutive on lesions of the nerve-centres have pretty frequently their seat in the joints. The differences which these articular affections present, according to the nature of the primitive lesions, authorise us to distinguish two principal groups of these. The first comprehends those resembling acute or sub-acute rheumatism, that is accompanied by swelling, redness and pain, sometimes rather acute and sometimes ending in effusion into the joints. Acute or sub-acute inflammation of the joints of paralysed limbs may also arise in myelitis, as is shown by the cases of Gull and others where joint affections developed themselves whilst eschars were arising. In the joint affections of hemiplegic patients, described first in 1846 by Scott Alison and then by Brown-Séquard, these are limited to the paralysed limbs, and particularly to the upper extremity. They occur more frequently after softening of the brain, more rarely after cerebral hæmorrhage. They habitually arise fifteen days or a month after the attack, at the moment of the appearance of tardy contractions, or even later than this. We easily comprehend the interest which these affections present in a diagnostic point of view, since acute articular rheumatism is an affection which is often bound up with certain forms of cerebral softening, and also sometimes appears after wounds. On the other hand, many spinal affections are wrongly attributed to rheumatism, because of the existence of joint complications. The clinical characters which make the latter easily recognisable are principally :—Their limitation to the joints of the paralysed limbs, and the co-existence of other disorders of nutrition of the same kind, such as eschars, and, when the cord is affected, acute muscular atrophy and cystitis, &c. The type of the second group of spinal joint affections is met with in locomotor ataxy. This affection coincides, it may be said, with the *début* of the ataxy. Without any external cause, a swelling of the limb may appear, generally without pain or fever. In a few days the general tumefaction disappears, but there remains at the level of the joint a swelling resulting from hydrarthrosis. One or two weeks after the invasion we find a crackling, which shows an already grave alteration of the articular surfaces. Consecutive luxations sometimes occur. These joint affections occupy most frequently the knee, the shoulder, or the elbow. The ends of the articulations become sometimes greatly wasted. Thus, in three months' time, the head of the humerus may become entirely destroyed. M. Charcot remarks that there is usually complete absence of any traumatic, or rheumatismal, or gouty cause for such phenomena. Volkmann has given it as his opinion that the joint affections of ataxic patients is simply the result of the distortion which the ligaments undergo; but they occur also in the upper extremity. The clinical characters of these joint affections are truly specific. The *début* is sudden, marked by a general swelling of the limb, not produced by ordinary œdema; the rapid alteration of the osseous surfaces, and, lastly, its appearance at a determinate epoch of the disease to which it is related, are all curious.

The following is the direct answer to the question as to the cause of the joint affection. Believing, as M. Charcot did, that it was, indeed, a lesion belonging to

the spinal affection, he found by minute examination that it could not be attributed to any lesion of the nerves of the periphery. He therefore believes that he has shown that the lesions of the grey matter of the cord are the origin of these joint affections in locomotor ataxy. It is not rare to see the grey matter affected in this disease; but generally it is only so in the posterior horns of the cord. But this was not the case in two cases of locomotor ataxia with joint affection, in which microscopic examination was made of the spinal cord. The anterior cornua were, in these two cases, remarkably atrophied; a certain number of nerve-cells, especially those of the external group, had disappeared without leaving any trace. The alteration, besides, was chiefly noticeable in the anterior cornu on the side corresponding to the articular lesion. It was seated in the cervical region in the shoulder-joint affection, above the lumbar region in the knee-joint affection. Above and below these points, the grey substances of the anterior cornua were healthy. From all of the foregoing, it is probable that the inflammatory process, primarily developed in the posterior columns of the cord, by extending itself gradually to certain regions of the anterior cornua, has been enabled to develope the joint affection. If this were the case, we might naturally be inclined to admit that the joint affections of myelitis and those ensuing after softening of the brain result from the invasion of these same grey regions of the spinal cord. In the case of cerebral softening, the descending sclerosis of one of the lateral columns might be looked upon as the point of departure of the diffusion of the inflammatory process. Remak and others have recently remarked, in progressive muscular atrophy, some joint affections which much resemble by their characters the joint affection of the ataxy. There is nothing which ought to surprise us in this, when we consider that a lesion of the nerve-cells of the anterior cornua of the grey matter of the cord appears to be the origin of progressive muscular atrophy.

THE BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

[LETTER FROM OUR SPECIAL CORRESPONDENT.]

Reception Room, Liverpool,
21st September, 1870.

THE Fortieth Meeting of this Association has, without doubt, been a special success. The previous Liverpool meeting had been held sixteen years before under the presidency of the Earl of Harrowby. The progress of the town, with its gorgeous buildings (unequalled out of London), is but typical of the stride that science itself has made in this term of sixteen years. The local papers seem to think "the present gathering not so remarkable for the presence of distinguished men as that held here on that occasion." We confess we do not see the point of this observation. When we meet in street or platform the familiar faces of Tyndall, Huxley, Murchison, Cobbold, Farr, Gassiot, Houghton, Jevons, Lyell, Lubbock, Lankester, Stokes (Cambridge), Rolleston, Richardson, Roscoe, Angus Smith, Thomson, Williamson, Grove, and many others who are the bone and sinews of progressive knowledge—can we wish for much more.

It is true that we missed the foreigners. This branch of the visitors forms one of the most admirable adjuncts of such meetings as these, but the iron grip of war has for a time barbarianized those great countries, Germany and France—the cradles of science—and Great Britain has on this occasion been thrown upon its own resources, and we must confess that it has done its duty well. Although restricted from this particular feast of Minerva, we have no doubt that science will, like the Phœnix, rise with redoubled vigour amongst our continental brethren.

The visitors at the Liverpool meeting had an opportunity of listening to perhaps two of the finest orators within the realms of science. The president is, perhaps, one of the best chairmen, or impromptu speakers, I have met, and it is really a treat to have dropped across him in a "Sectional Meeting." The palm of oratory must, however, be awarded to Tyndall, whose excellent constructive faculty, finely rounded phrases, and rich imagery, creates a feeling of intense pleasure to the listener. A slight touch of verbosity occasionally mars them, but what of that, it is no import. His discourse "On the Scientific use of the Imagination" is an *Essay* equally suited to quiet perusal as it was to delivery.

In the Chemical Section, on Tuesday last, Professor Williamson brought before the members present, the important question of Government Aid to Science. It seems that the Government Commissioners propose forming a college of their own for the Indian Service. He condemned this, and other contemplated recommendations. The feeling against Government monopoly of scientific education is strongly felt, as it should be, by the "B.A.s"; and, when we consider that the Commission was instituted at their request, their opinion, if firmly expressed, should have considerable weight. We want State aid, but not monopoly. We want development of talent, not a Government nomination.

The Geographical and Biological Sections, as usual, attracted a large concourse of outsiders. Letters, such as Sir Samuel Baker's, from the White Nile in Africa, and Sir Roderick Murchison's communication about Livingstone, could not fail in attracting all the non-scientific public.

Dr. Brown-Séquard, and his papers, created a considerable amount of interest, particularly as there was an attempt to condemn vivisection by practically stopping all grants for researches in which vivisection was used. As regards the use of vivisection for lecture demonstration, it is, perhaps, open to discussion, but that such can be prohibited in original research is absurd.

The prevailing topic at the Liverpool Meeting has been Biogenesis and its attendant phenomena—changes produced by germinal ferments—infectious diseases of the animal and vegetable life, &c. The term Biogenesis is used by Huxley to express the hypothesis that living matter always arises from the agency of pre-existing living matter.

The President's address was completely taken up with this and kindred subjects. The discourse of Tyndall was inseparably connected with them, whilst there were no less than twelve or more section papers all dealing with these interesting points of investigation. Mr. Tichborne entered into the chemical part of the question in the Chemical Section, which brought forth Professors Roscoe, Williamson, and Angus Smith.

The Committee Reports were elaborate and important, but it would take up too much space to do them justice, suffice it to say that all went on as merrily as marriage bells, and only one little point tended to mar the hilarity of the Meeting for 1870, it was the severe and sudden illness of one of the most valued and well-known members of the Association. His necessitated return to town cast for some time a gloom over the section, where he was so much respected.

Diphtheritic Paralysis.

DR. LEUBE reports a case (*Arch. f. Klin. Med*), in which in addition to the loss of motor power, there were lowering of the sensibility of the skin, and complete loss of sensation in the mucous membrane of the larynx above the free border of the vocal cords; whilst coughing was excited as soon as a sound was passed below the glottis. The difference is explained by the lower part being supplied by the tracheal branch of the recurrent as well as by the superior laryngeal nerve. The patient was fed for ten days by means of an œsophageal tube, and treated with strychnine, injected subcutaneously in doses of gr. 1-12 to 1-4 daily. There was rapid improvement in all the symptoms.

WEDNESDAY, SEPTEMBER 28, 1870.

BABY FARMING.

Margaret Waters has been found guilty, and sentenced to death. This conclusion to the case which has so long agitated the public mind is not surprising. From the details that had already been published, and from what we had otherwise learned, we were quite prepared for it. Until the trial had been held, we felt it right to refrain from the expression of such an opinion, but now there can be no reason for reticence. We may therefore freely state that we have no doubt that the case in question is only one of many in which traffic in human life is constantly carried on, and that some steps ought to be taken to put an end to such a scandal.

Before we offer our own suggestion as to the step we consider advisable, we may, however, stay to make one or two casual observations on the trial itself. In the first place we are not at all pleased with the professional evidence as related in the newspapers. We do not question that narcotics had been employed as believed by all the medical men who saw the infants. The symptoms were, in fact, unmistakable. But we object to the very positive terms in which some asserted that such agents should *never* be given to young people. Of course, everyone knows that the younger the child, the more susceptible is it to the influence of narcotics, and that they ought never to be administered except with great caution, and under medical advice. But we are free to confess that we have ourselves given opiates to infants with great success, and that we do not intend to exclude them from our pharmacopœia, although told rather flippantly that they kill babies "like a shot." Many years ago we related to a coroner our practice in this respect, and thereby saved a brother practitioner from an undeserved rebuke, which might have resulted from such positive testimony as that given in the case now under consideration. There is another point in this respect, everyone knows that many soothing syrups and other nostrums, freely sold by chemists, contain opiates, and are constantly administered without medical advice to young children by the most affectionate mothers. We admit the practice is to be reprehended as highly dangerous, and the public sale of such compounds is a disgrace. But the practice exists. Nay! Is so universal, that if minute doses of opium were generally fatal to babies, there would be few grown up people in these islands.

We may congratulate one witness that he did not countenance the absurd notion of the public that lime-water was added to the milk of these unfortunate infants with the view of poisoning them. Even baby farmers need not be painted blacker than they are, and it is quite possible that lime-water was used in good faith.

Let us guard against misunderstanding. We are not controverting the statement that drugging in excess was resorted to, to shorten the lives of the babies at Brixton—the evidence on that point is clear enough. There is, therefore, the less necessity for exaggerating the dangers of giving opium to children, and in a Law Court we do not like to see statements so sweeping as to exclude exceptional instances.

Having discharged a duty as Medical Journalists, in alluding to this part of the subject, we have no intention of following the other particulars of the case. The public has at last learned what many have long felt assured was the horrible practice. A case has been tracked home, and yet we do not think that it is an isolated one; nor do we believe it is the worst in existence. We are now brought face to face with a social plague-spot, that demands the earnest attention of all, and opens up many problems to which we have not to-day space to allude.

Nor is the subject new. These recent disclosures carry us back to the early part of last century, when, as described by Captain Coram, numbers of helpless infants were found exposed by the roadside. Indeed, we appear to have retrograded, for in those days there is reason to believe the little victims were the offspring of the poorer classes, in the present many of them evidently belong to persons removed from the immediate pressure of pecuniary difficulty. In the columns of this journal, we some years since, inserted a series of letters disclosing the nefarious practices of advertising quacks, who, under various aliases, ministered to the vices of the age and fleeced their victims. We have since helped to expose the evils of Baby-farms and the practice of Baby-farming, it is now our purpose to direct attention to the existence of a kindred evil, not less serious in its nature, and we fear even more murderous in practice.

From enquiries we have instituted, we have reason to know there are in London and its suburbs numerous establishments in which "ladies may receive every attention during confinement, and be assured of the strictest secresy." The mere fact of a woman seeking such a place, for her hour of trial is *primâ facie* evidence of the child being not welcome; for what female legitimately about to become a mother would desire to be amongst strangers at such a time? The proprietors of these establishments, well versed in the practice of their art, undertake all the duties of midwifery, and there seems to be little doubt, although legal proof may be wanting, that in some cases the infant never sees light but is ruthlessly stifled in its birth. These houses are well known to the police, who are convinced that it is from them that the still-born babes found in the neighbouring gardens must have come, but they are unable to prove it therefore are prudently silent. Yet, day after day, bodies are found in the streets

and squares of London, scores in each week, thousands every year, and nothing is done to check the practice.

We may be asked what can be done? As we have pointed out the evil we may be fairly called upon to prescribe the remedy. In the proceedings of the Commission of Inquiry into the Trade outrages in Sheffield, we have a precedent which it would be well to follow in the present case. As we have stated the police can point out the houses and find the occupiers. Cannot a Royal Commission be appointed to induce some of their accomplices by fear of punishment or hopes of pardon to disclose the working of the system, and devise some means for regulating such establishments by placing them under the inspection of competent medical officers?

Notes on Current Topics.

About the War and Wounded

Under the date of September 12th, 1870, a Paris Correspondent writes to us as follows :—

I suppose I must tell you something more about what is going on in this sad city, with respect to the ambulances. It has been noticed that the wounded soldiers who arrived recently at the terminus of the Strasbourg railway after the last combats, in place of being installed, as they generally have been, in closed railway compartments, are laid on straw in open waggons. This mode of transport is recommended by many doctors as being more wholesome, and is to be adopted whenever the weather is fine enough to permit of it. It is curious that waggon ambulances have not been adopted, like those made use of in the United States during the slave-war. Dr. Evans, of nitrous oxide celebrity, writes to say that, in that war a very large number of the wounded had to be transported by rail to the Northern States. Now, the shaking of ordinary carriages exposed more or less the wounded to painful tortures. Accordingly, in order to lessen or prevent these, a member of the Sanitary Commission devised the model of a waggon, which, by mechanical means, might assure the comfortable transport of the wounded. Twelve of these carriages, communicating between the army and the hospitals, were constantly in use. Litter-beds, which could be detached at will, without disturbing the patients, are disposed regularly on each side of the carriage, and hung by means of india-rubber bands which lessen the shocks. The ventilation was carefully attended to, and the light softly tempered. There were pipes for communicating with the surgeons and the male and female attendants. These latter had in their care, neatly packed, provisions of tea, coffee, and drugs; a neat stove for cooking was in the carriage, &c. Dr. Thurston, director-general of the Medical Department of the Army at Nashville, said he was persuaded that the rapid transport, the careful treatment during the journey, and the care of the attendants had saved many lives. And Dr. Barnam made the observation, that he had transported 20,472 patients by railway, and only lost one of them. It is a great pity that, as the French and German people have determined to kill each other for some reason or other, which I, as a non-fighting man, do not understand, the Army authorities had not been obliged to pass an examination in that admirable work *the Sanitary Commission of the United States.*

Dr. Savoye, an old M.P. here has put his house at Excideuil at the service of the wounded, and Clichy prison has been put to the same good destination. Versailles and St. Cloud palaces, too, are to be used for ambulances. So much for utility as against imperial splendours. There are four sedentary ambulances of the Parisian press, one at the Ecole des ponts-et-chausies, in the Rue des Saints-piers, another in the Avenue de l'Empereur (now I believe called the Avenue de Victor Noir), a third in the Rue de Courcelles and the fourth in the Conservation des Arts-et-metiers. Another ambulance of forty beds is established at Courbevoie by the inhabitants by private subscription, and the splendid chateau of the Central Society of Agriculture at Harcourt (Eure) has been made into an hospital.

An admirable writer in the *Mouvement Medical* advises that courses on diseases of armies and special lectures on bandages and the dressing of wounds should be carried on continually, and that there should be also lectures on the hygiene of camps at the same time. According to the *Debats*, there are a good number of the wounded soldiers from Reichsoffen now in the military hospital of Versailles. It is said that the stupid *intendance* has kept many military surgeons at Versailles, instead of allowing the patients to be attended to by civilians, and sending the surgeons to the Seat of War, when they were so greviously wanted recently. The best thing the poor senate did just before its dissolution, was to grant the whole of the vast space it had at its command for an ambulance. M. Nélaton, himself a senator, was to be the director-general of this great ambulance, and the physicians appointed were Dr. Boyer and Dr. Constantin Paul. It is said that thousands of Prussian soldiers are in the hospitals of Nancy and other towns, suffering from choleraic dysentery. Would that such miseries would soften the hearts of Bismarck and the fatalist King of Prussia, and make it more easy to make peace in this distracted land. A touching visit was recently made by the secretary of the ambulance of the Parisian Press, accompanied by other gentlemen to the wounded soldiers in the military hospitals in Paris, in order to ascertain which of these poor fellows would like to be sent home to their native villages and to assist them and their families in case of needy circumstances. This is to be done to all the hospitals for wounded throughout France. Verily, we advance in civilisation in some things although, we appear to retrograde in others. The following letter has been written to General Trochu (*Union Medicale.*)

"General, I take the liberty to recommend to all your solicitude the organisation of the surgical service of the Garde Nationale Mobile, which in a few days may be in face of the enemy. As it at present is constituted, each battalion has only an assistant major, chosen among the students, who are even materially unable to give in most cases any efficacious assistance. I have every reason to believe that if an appeal were made to the young doctors of the civil hospitals, they would not be long in sending in their names, too glad to be of service to their friends.

"Signed, Hourteloup."

It has been announced that M. Husson intended to retain all the "internes" in the Parisian hospitals. But whatever was his attentions, it is certain that most of the hospitals are wanting in these constituents of their staffs.

Russia, it is said has appointed a commission to create a medical reserve of 1,000 surgeons. How much better would it have been for the combatants had such a step been taken by them. We have already urged that this should

be done, and we would repeat that large numbers of our Army Surgeons ought to have been sent to gain experience in the field, and help the sick and wounded.

Cattle plague is seriously inconveniencing the Prussians, especially round Metz.

Fever, cholera, and dysentery are also committing ravages, the extent of which is being, as far as possible, concealed. When, after the war, the long list of dead is reckoned, it will be seen how terrible has been the havoc of disease.

The Irish assistance has been gratefully accepted by France.

Extraordinary cases are alluded to by many correspondents, and after the war is over we do not doubt that most valuable contributions to military surgery will be made. We are only sorry so few of our own military brethren have been sent to profit by the awful lessons.

Of the numerous letters from the Seat of War, communicated to the papers by the National Society, that of Dr. M'Cormack, dated Sedan, September 16th, and published in all the dailies last Saturday, will attract particular attention. Our respected *confrère* is chief of the Anglo-American Ambulance at Sedan, and his former contributions to our columns will make his name familiar to our readers. We regret we have no space for extracts.

The Liverpool Reports.

We cannot say much for the reports of the Liverpool Scientific Congress that have appeared in the papers. Is it the war that has upset the reporters, and made the staff look upon the Congress as a bore. Even *Nature*, to which we looked this year to supply such an account as we should like to see, has disappointed us. When we saw *Nature's* preliminary articles on Liverpool, we exclaimed, now at last we shall have an accurate and complete *resumé* of everything. But patience, perhaps another year we shall have peace, and then science may be better served. There is enterprise enough amongst us, and nowhere more manifest than in *Nature*, but here, we fancy, a golden opportunity has been thrown away. The journal of science, *par excellence*, was the one to give a perfect account of the Scientific Congress of the year.

Nephrotomy.

A new operation is likely to be introduced under this name. In the *Annales de la Soc. Méd. de Liège* are given the particulars of a case of successful excision of the entire kidney. The operator was Professor Simon, and the occasion was the following:—Having met with strong and extensive adhesions in a case of ovariotomy, M. Simon was obliged to excise at once the two ovaries and the uterus itself. The left ureter, involved in these adhesions, was divided, and from this, notwithstanding the cure, a double fistula resulted; one opening being situated below the umbilicus in the abdominal cicatrix, and the other in the stump of the cervix uteri and vagina. It being impossible to effect the occlusion of these fistulas by the autoplastic process, M. Simon attempted the extirpation of the kidney. Taking his stand on the fact that ovariotomy, uterotomy, and splenotomy are even more serious as regards the injury done to the peritoneum, and supposing that the function of the excised kidney might be performed by its fellow, he made some experiments so as to judge beforehand of the chances of this operation. Four dogs were submitted to it, of which only one died, the other three recovered. From this he concluded that life is compatible with the removal of a kidney.

On the 2nd of August, 1869, the operation was performed at the hospital of Heidelberg as follows:—The patient being chloroformed and laid on her back, a first incision of the integuments was carried from the lower edge of the eleventh rib to half-way between the twelfth and the crest of the ilium at a distance of some six centimétres outside the spinal apophyses of the vertebra. Then dividing layer by layer the subjacent tissues, the aponeuroses of the internal oblique and tranversalis muscles, he pressed down the external border of the sacro-lumbalis, along which the incision had been made, and the quadratus lumborum was divided. The kidney being thus exposed without the infliction of injury on the greater or less abdominal nerves, or on any important organ, its cellulo-adipose capsule was opened from above downwards, and the organ itself, isolated, enucleated with the finger, sprang out. A firm ligature was applied to the renal vessels, and the excision was made, leaving only a portion of the hilus intended to act as a *point d'appui* to the ligature, and to prevent it from slipping. A few sutures reunited the two edges of the incision. Forty minutes sufficed for the performance of this delicate operation.

Next day bilious vomitings, probably due to the chloroform, ensued without much fever. The urine was turbid, and in small quantity; there was suppression of the discharge by the fistula. Skin moist.

Pulse from 130 to 140 on the third day; symptoms of incipient peritonitis. No trace of the paralysis of the lower limbs observed in the dogs which had undergone Nephrotomy. No delirium. Local state satisfactory; pus in small amount and healthy; proud flesh at the bottom of the wound. Some points of suture were removed. On November (August?) 13th, there was no longer any fever, appetite good; the patient regained strength, and began to sit up. On the 29th, the wound had cicatrised, except the opening for the ligatures, discharging one or two drops of pus daily, the patient left hospital quite well some days subsequently.

"Peculiar" Idiotcy.

The direction of the learned judge that the jury should acquit the "Peculiar People" of criminal negligence in omitting to obtain proper medical aid for their dying child, appears, though no doubt strictly legal, as illogical and unmeaning, in the light of common sense, as the mania of the Peculiar People themselves. His lordship directed an acquittal because the medical witnesses would not swear that the child would certainly have recovered if due medical care had been given.

The evidence was thus literally at fault, because there was no absolute proof that the witholding of treatment was the certain cause of death.

But what witness can conscientiously swear to such a statement? Who can say that any patient would certainly have lived, or would certainly have died, if such and such things were done. Such a dictum does not belong to anything humane, and it seems therefore ridiculous to require from a witness any more specific declaration than that the child's chances of recovery were criminally prejudiced by witholding medical aid.

The Yellow Fever in Spain.

A most alarming report has come to us of the existence of a frightful epidemic of yellow fever in Barcelona in Spain, to which more than 1,000 persons had already succumbed.

A correspondent of the *Glasgow Mail* communicates to that journal a statement on the subject, which throw ridicule and doubt upon the statement and which we give *quantum valeat*, because it seems to us not in the least improbable that an outcry about fever might be discounted by the Spanish authorities at a very good price.

The correspondent says :—

"It has gone all over Europe that the yellow fever exists at Barcelona. So it does—officially. But I hear on excellent authority that it is not the real yellow fever of the tropics at all, but a 'relapsing fever,' such as prevailed in London a year or two ago—stimulated, no doubt, by the smells from the harbour, which has been dredged lately, and by the dirty habits and poor style of living of the inhabitants of the quarter in which it appeared. Nevertheless, the Board of Health (Junta de Sanidad) maintains that yellow fever exists, and Barcelona has been declared 'foul,' and placed in quarantine. Spanish officials love quarantine, for it gives admirable opportunities for corruption; and what do they care about the commercial losses of other nations? The Barcelonese fever was supposed to be brought by a steamer from Havannah. That steamer was notoriously in a suspicious condition, but its passengers were allowed to land on paying half a dollar a head! Now mark how an act of this kind—dishonest in itself—falls peculiarly hard upon foreigners. Soon after the arrival of the Spanish steamer just mentioned, and the panic consequent on the rumours of yellow fever, comes an English steamer from Marseilles, with a clean bill of health, and free from illness. The Junta de Sanidad immediately make her the scapegoat—the populace being enraged against themselves—and send her to Port Mahon for ten days' quarantine, on the pretext that, though having come clean from Marseilles, she had loaded in the Black Sea. By this measure a loss of hundreds is imposed upon the steamer's owners, and she has to run the risk of her cargo of wheat being spoiled.

Disease in Omnibuses.

Last Monday morning was very foggy in London. Getting into an omnibus we were a little surprised to find among the passengers (in its mother's lap) a child in a paroxysm of whooping-cough. Many are the reflections suggested by this incident. The explanation was that the child was on the way to one of the large hospitals. If whooping-cough, why not measles also, or scarlatina, or any other disease? The public is more interested than the Profession in this matter.

Nitro-Glycerine.

New interest is attached to this substance by the report of its employment in war. It is said that it may be kept in a condition in which it will be harmless by mixing it with alcohol.

A Baby Show.

Our attention has been directed to a disgusting exhibition, yclept a Baby Show, held at Clay Cross on Friday last, in the Auction Room of a Mr. Pearson. We know that Clay Cross is noted for the superior quality of its coal, but we were not aware the residents were so foolish, or that eighteen mothers could have been found mad enough to enter their last born as candidates in competition for a set of trays, the vulgar offering of some cheap John. However eighteen mothers did enter their children. Two persons were selected from a vast concourse of people —colliers, we presume, out for a holiday—whose society the auctioneer courts to weigh the candidates. The child of a woman named Collidge, weighing 28¼ lbs., stood first on the list of the eighteen; and the next weighed 25¾ lbs. We learn further Mr. Pearson presented each unsuccesssul child with a useful bread knife!—to eat its pap with? Is there no clergy in power at Clay Cross, or do they want the services of some indefatigable missionary who will try to civilize them? This baby-showing needs suppressing with an iron hand, and we hope to have no more of them.

The Operation of the Contagious Diseases Acts.

A report of the Chief Commissioner of Police to the Board of Admiralty on the Operation of the Contagious Diseases Acts in the Plymouth and Devonport district has just been presented to Parliament.

The Commissioner says these Returns show that 7,766 women have been placed on the Register, and that the following numbers have been removed therefrom, and for the causes stated :—

Left the district	2,558
Married	385
Entered homes	451
Restored to Friends	1,249
Died	107
Total	4,750

Leaving 3,016 still on the Register.

The Returns also show a decrease by one-half of the number of men in hospital for contagious disease.

In order to show the beneficial operation of the Act, I am desirous of calling particular attention to the effects produced at Plymouth. There has been, from year to year, at this station a steady and increasing diminution in the number of brothels, as likewise of prostitutes frequenting the same; the brothels have decreased from 356 to 131, and the number of prostitutes from 1,770 to 645.

When the Act of 1864 was first put in operation, over 300 of the youngest prostitutes left the neighbourhood. These were mostly country girls from the mining districts, of which there were then large numbers practising prostitution at Plymouth and its neighbourhood; and as many as 12 and sometimes 18 herding together in one house, in the utmost filth, wretchedness, and disease, and in such a condition of privation that clothing had often to be obtained for them by the police before they could go with decency through the streets to the hospital.

As a proof that the places of those giving up prostitution are not filled by new comers, whole streets in which many, and in some cases most, of the houses were brothels, and the principal part of the inhabitants prostitutes, before and some time after the first Contagious Diseases Act came into operation have now but one or two prostitutes living in them.

For example, Castle street, Plymouth, and Castle Dyke lane adjoining, which formerly contained 132 prostitutes, have at the present time *two* prostitutes only living in them.

The following particulars, extracted from the Register at Plymouth, show the beneficial effect of the Act up to the 26th March, 1870 :—

Entered homes - - - -	203
Restored to friends - - -	693
Married - - - - -	161
Left the district, and, in many cases believed to have returned to their friends - - - -	658

And in addition to the above, more than 500 young girls, found in houses of ill-fame, have left the district and returned to their friends on being spoken to by the police, before being brought under the provisions of the Acts.

The same results are observable at other stations only in a less marked degree ; for instance, at Woolwich:—

Entered homes - - - -	68
Restored to friends - - -	102
Married - - - - -	45
Left the district - - - -	287

Whilst the decrease of disease amonst the women is likewise remarkable. I may mention Chatham ; the disease in—

1868 was - - - - -	70 per cent.
1869 „ - - - - -	18 „
1870 „ - - - - -	6 „

Clandestine prostitution, particularly amongst married women and servant girls, has much diminished ; this, in all probability, proceeds from the fear of being brought under the operation of the Act.

The improvement that has taken place in the persons, clothing, and homes of the common women, as regards cleanliness and order, is most marked. Many of the women formerly looked bloated from drink, whilst others were greatly emaciated, and looked haggard through disease. Their language and habits are greatly altered—swearing, drunkenness, and indecency of behaviour have become quite exceptional ; the women now look fresh and healthy, and are most respectful in their manner ; in fact, these poor creatures feel that they are not altogether outcasts from society, but that there are people who still take an interest in their moral and physical welfare.

William C. Harris,
Col. Henderson, C.B. Assistant Commissioner.

Submitted for the information of the Lords Commissioners of the Admiralty.

E. Y. W. Henderson,
Commissioner Metropolitan Police.

The Cost of the Highgate Infirmary.

The finance committee of the guardians of the poor of St. Pancras have just made a return of the entire cost of the Highgate Infirmary, about which so much uproar was created at the commencement of last year, when it was declared by the opponents that a sum of £100,000, would scarcely cover the outlay. From the return which has been furnished by the guardians to the managers of the Central London Sick Asylum district, it appears that the total cost of this large establishment, ready to be handed over to them, is £49,659 8s. 6d. The managers have referred the statement to a committee to report, when the cost will be subdivided and apportioned between the several parishes forming the district, and the parish of St. Pancras be recouped the difference between the entire cost and there own share of it.

The Naval Medical Service.

The following is the abstract of the meritorious services which have recently secured promotion in the Naval Medical Service for the following officers :—Staff-Surg. H. Slade entered the service on the 4th of June, 1847, and was employed as assistant-surgeon on the Coast of Africa, Home, and East Indian Stations. He was promoted for services in the Burmese war ; and served as surgeon on the East Indian, Home, North American and West Indian, Baltic, South-East Coast of America, and Australian stations. He distinguished himself on two occasions by his attention to the wounded after the actions of Pakehinahina and Gate Pah in New Zealand, in 1864 and 1865. Staff-Surgeon William Bennett Dalby, M.D., entered the Navy on the 12th of May, 1846, and served as assistant-surgeon on the Home and Mediterranean stations, and at Plymouth Hospital. As surgeon, he was employed during the Russian war at Therapia Hospital, and subsequently on the Home, Cape of Good Hope, and West Coast of Africa stations ; at Haslar Hospital, and as medical officer in charge of the naval cadet's sick quarters at Dartmouth, where he his still serving. He has been specially commended for his services on several occasions. Staff-Surg. Ahmuty Irwin entered the Navy on Jan. 4, 1851, and served as assistant-surgeon at Plymouth Hospital, on the South-East Coast of America and the Mediterranean stations, and with the Naval Brigade in the Crimea, where he was severely wounded. As surgeon, he has been employed on the Mediterranean, Home, West Coast of Africa, East Indies and China, and North American and West Indian stations. His name was mentioned in the *London Gazette* as being continually under fire when attending the wounded at the capture of Ningpo from the rebels in 1862. Mr. Irwin is now serving at Plymouth Hospital.

Damp Churches.

It is surprising at this season of the year, when people are most affected by atmospheric changes, the apathy or indifference which exists in country places of having the damp, sepulchral air of churches, locked up during the other six days of the week, improved by heating before the congregation assemble. We have known persons predisposed to thoracic affections, suffer severely by sitting in cold churches throughout the morning service. All we can say is, that when the temperature and condition of the atmosphere of churches are neglected, that it is an essential of great moment overlooked , and that persons coming to worship are thereby made to suffer, not through incaution on their part, but owing to utter carelessnes on the side of those who should know better. Our remark will meet, it is hoped, with the attention which the importance of the subject demands.

A Pestilential Swarming of Aphides.

Owing to the long protracted drought, turnips, cabbages, and other varieties of vegetables, have been seriously injured by the "fly." It was expected when rain came that the insects would have been washed away, and thus de-

stroyed, but instead, they seem to thrive the more ; and, during the last few, warm, sunshiny days, the atmosphere has been literally filled with these entomological creatures. We learn that in agricultural districts where turnips are cultivated, and that in towns where the sanitary arrangements of the locality are defective, and the sewage insufficient, that swarms of *aphides* swarm the air from noon to sunset, making it uncomfortable and injurious to the people since they find their way into their eyes, mouth, and nose. We understand where these prevail in such superabundance that thoracic diseases are very prevalent. We believe districts bordering on the sea are exempt from this pestilential swarming of aphides, so prevalent in the Midland Counties.

The Skins of old Silk Hats for the Wounded.

We know of no better substitute for lint than the skins of old silk hats, if washed and dried after being removed off the hat. We have known them used in preference to lint, and we are surprised to think that so many are put aside as valueless when such excellent use might be made of them at any time, but more especially at the present moment when lint, and everything pertaining to it, is in such earnest request by the humane for dressing the wounds of the injured soldiers in the Franco-Prussian War. There are few households in which a few old hats are not to be disentombed. We recommend their skinning, washing in soft water, and drying slowly, and afterwards being forwarded to those whose mission is catering for the poor stricken down soldier, and we promise that they will be found of great utility in the hospitals, and of much value to both surgeon and patient.

Nice and Mentone.

Last week we felt it our duty to warn medical men against advising patients to winter in Nice, Mentone, Monaco, &c. As we predicted, the attempt has already been made to represent these places as quite safe, and even the English Consul has written to make light of the disturbances that have occurred. It would be easy to imagine that very sad scenes might take place without our consul knowing much about it in his summer retreat up the mountains. But, admitting that the disturbances have hitherto been slight, we repeat that ever since its annexation to France, Nice has been but a smouldering volcano that may at any moment burst forth. Present events are certainly exciting, and we have received notice of several violent demonstrations in the Southern towns of France. But besides the danger of anarchy, which seems to rapidly increase, it is not to be forgotten that there is considerable difficulty in the mere journey, and even supposing peace to be shortly proclaimed, famine in many districts may bring famine prices throughout the country. On the whole, we repeat our advice to select from the numerous English winter resorts, and for this year at least forego continental travel.

A Correspondent's Reward.

One of our correspondents who has, within a few weeks, interested himself in the controversy as to the possibility of celibacy, informs us that he has received from an anonymous donor, of the tender sex, as an offering in acknowledgement of his courageous defence of those on whose charity doubts were thrown, a pearl necklace, with a silver crucifix attached, which the fair donor says has been blessed by His Holiness the Pope. This spiritual treasure was enclosed in a rather material and undignified envelope—a pill box—and with it a very strong and thoroughly feminine denunciation of the correspondent who originated the presumed slander.

Army Medical Department.

The United Service Gazette understands that a new grade of commissioned officers is likely to be established in the Army Medical Department. At present there are but two captains of orderlies employed in the service, one at Netley, and the other at Woolwich. It is the duty of these gentlemen to superintend the servants in the hospital, and to relieve the principal medical officers of many of those executive functions which tie the hands of the doctors in the smaller hospitals. It has been proposed, therefore, that in all hospitals of any size, such as garrison, camp, and general hospitals, there shall be an officer to supervise under the principal medical officer, and that his rank shall be ensign, lieutenant, or captain, according to the accommodation for patients in the building. It is stated that these appointments will be offered to assistant and deputy purveyors, both on the active and half-pay list.

Dispensers at the Naval Hospitals.

The United Service Gazette says that all dispensers now in the service who pass the examination ordered for their class will receive the new rates of increased pay. Those dispensers who do not pass the prescribed examination will retain their old rates of pay, and receive in addition a sum as store allowance.

Spermatic Disease.

We regret to observe the following advertisement in our contemporary *The Boston Medical and Surgical Journal* :—

"IMPROVED SPERMATORRHŒA RINGS—of pure silver, for preventing and curing Nocturnal Emissions. Price $3—to physicians, $2. They can be sent by mail in a letter.

"Sold by E. M. SKINNER, Chemist, &c., 287 Tremont street, a little south of Boylston street, Boston, Mass."

Such appliances, as we have already shown, only tend to keep up the disease, by producing local irritation and the concentration of the mind on the subject. Such an advertisement should not be admitted into the columns of a medical journal.

The Obstetric Position.

Whilst the universally recognised obstetric position in Great Britain is having the woman placed on her left side, with the buttocks near to the edge of the bed, the knees raised upwards towards the abdomen, and the chest bent in a downward and forward direction towards the knees, we regret to be informed that the very disgusting and dangerous position of keeping the patient in a kneeling posture, with the head and elbows resting on a chair, is very generally followed in the County Palatine of Lancashire, and some parts of Cornwall. In the important towns of Blackburn, Bacup, Todmorden, and Burnley, we learn with horror that not only do the midwives practice

this method of delivery, but that, in only too numerous instances the doctors countenance it, whether from its being a custom of the country insisted on by the women, and practised with the twofold object of convenience and pleasing, or that the position is considered to facilitate parturition, we are not prepared to say. But, in raising our protest against a brutal habit, disgusting in the extreme; for surely it is a degrading sight to see a woman on her knees, leaning upon a chair before her, with a shawl tied around the abdomen, which, upon the occasion of a labour pain, is tightened by the attendant, who places a knee upon the patient's back, and pulls upon the knotted shawl with all vigour. We are alarmed at the after consequences, when the delivery of the child is effected, and the placenta removed; the woman is undressed of her everyday garments, new linen put on, a binder adjusted, and then walked off to bed, hence flooding is very usual—and who can wonder at its occurring? We give the Lancashire people every credit for cleanliness, and for thrift; but in exposing their women at the time of parturition to great danger, for the sake of saving a little additional washing, we highly censure them. We do not advocate the parturient going early to bed—every practical accoucheur knows the time when they ought, and he deserves much censure indeed if he patronises delivery in the manner we write about, in order to condemn. It is usual, we know, in protracted cases, for the patient to be allowed to suffer a pain or two kneeling, but to deliver them in that posture is literally disgraceful. In some parts of Cornwall the same practice exists. If medical men would only refuse to assist or deliver in that position, and take the trouble of explaining the danger consequent upon it, we believe the disgusting practice would die out.

The Tread-Mill.

Of all forms of punishment the tread-mill seems the most absurd, the most unhealthy, and unprofitable. It is one of the last remnants of a barbarian age, which we hope soon to see abolished, and a more useful, yet less rigorous system, combining profitable labour with healthful employment, introduced into our prisons. There are many dark tales, never disclosed, of horrible occurrences which take place on "*The Mill*," or disgusting consequences attending the irksome and monotonous "*tread*," which the turnkey never reveals. Fainting men, with broken shins, may be accused of laziness or carelessness; but when human beings taken off this horrible wheel of punishment have been known to die quickly, it is high time the subject was investigated, and some philanthropic Board of Superintendence would abolish the present wheel and suggest some-more healthful method by way of substitute and precedent for other gaols. Sydney Smith, as long back as 1824, lucidly directed attention to this irksome, dull, monotonous, and disgusting tread-mill, where a man does not see his work, does not know what he is doing, or what progress he is making. We cannot do better than quote his exact words. "There is no room for art, contrivance, ingenuity, and superior skill—all which are the cheering circumstances of human labour. The husbandman sees the field gradually subdued by the plough; the smith beats the rude mass of iron by degrees into its meditated shape, and gives it a meditated utility; but the treader does nothing but tread, he sees no change of objects, admires no new selection of parts, imparts no new qualities to matter, and gives to it no new arrangements and positions." The system of punishment, with an attempt at labour combined, is simply ridiculous, whilst it is not only cruel, but dangerous, entrusting the management of the wheel, and the persons selected to be put upon it, to ignorant turnkeys.

Correspondence.

MORE MEDICAL TESTIMONY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Dear Sir,—The valuable and interesting matter contained in the accompanying correspondence, which I have had with one of the oldest and most respected members of your Profession in this city, will be, I trust, in your estimation, my sufficient apology for requesting you to give it a place in your columns. Your readers, and the general public, will see in it, a further evidence in justification of the strong opinions expressed during the past quarter of a century or more, as to the injurious effects of alcohol on the human frame; and as to its utterly ruinous effects on all classes of society in a moral point of view. The address on this subject, in both its physical and its moral aspects, delivered so long since by my respected friend, comprises those arguments which might be expected from an enlightened physician, anxious at that early day in the Temperance reformation, to give public warning of the terribly deleterious effects and influences of alcohol on the health and morals of the people. And I consider the publication of the opinions of "Medicus" in the present day, peculiarly valuable, because it affords such good additional evidence to the truthfulness of the abundant similar warnings which have been given to an apparently paralyzed public, utterly unconscious of the folly,—I might say insanity, they are guilty of, in using alcohol as a common beverage. May this evidence be rapidly multiplied, and with similar right-good-will, by medical men, and other scientific men; until intelligent men shall be made ashamed of themselves for showing so bad an example to the ignorant, by using this poison as they now do; and until the manufacturers and retail dispensers of it, shall be made to fear the danger of a strong expression of public displeasure—such as is evinced in America,—for the mischief they are doing to society, and for which the wealth they accumulate should be considered by them, a miserable compensation. And it is only a few out of the large number engaged in this injurious trade, that are successful even in this regard; to the many, I have good reason for believing it is a source of loss instead of again.

I am, my dear Sir, very truly yours,

James Haughton.

35 Eccles street, Dublin, September 9th, 1870.

Saturday, September 3rd, 1870.

My dear Sir,—Your temperance papers (for which many thanks) remind me that I am no recent convert to the cause of temperance. More than thirty years ago, when I delivered at the Dublin Institution, Sackville street, a few Lectures on the best mode of improving the health of the working classes, in which I dwelt in the strongest terms on the evils occasioned to both soul and body by an indulgence in alcoholic drinks, and every recurring year since has convinced me of the soundness and propriety of the views then advanced. I feel thoroughly satisfied that the tissues of our frame, can be nourished, supported, and fitted for their proper functions, by good beef and mutton, eggs, milk, &c., together with the various vegetable compounds furnished by an allwise and bountiful Creator, and that all this assimilation may be effected without the aid of any artificial stimulant, whether in shape of small beer or sparkling champagne. It is said wine is the milk of old age. I am inclined to reverse it further, and maintain that good new milk is the wholesomest and best treatment for advanced life, milk being in fact white blood, and possessing all the elements of nutrition, but like the air we breathe it is not properly estimated by mankind. Either the stomach is in a sound normal condition or it is not, if in a healthy condition the proper stimulant is good healthy food, if not in a healthy state, assuredly alcohol is not the suitable remedy. Alcoholic drinks are only calculable as it were to provoke the digestive organs to accomplish, what they are incapable of effecting. Suppose your servant came in to you and said, "Sir, the horse won't take

his oats. I want a glass of whiskey, to assist his digestion." You are, I am aware, too polite to him, even to give him a rude answer, but in place of that, you would naturally say, "Well, James," or whatever the name may be, "since the horse is averse to take his oats, there must be something wrong with his intestinal canal. Give him a mash of bran, and a day or two of rest, and all will be right."

But I feel my dear Sir, I should apologise for entering so fully on a subject that you have so long, so eloquently, and so effectually advocated, but I have now, I may say at the close of a long and anxious life witnessed so much crime, so much *domestic* misery occasioned by this vile propensity that I cannot avoid giving expression to my feelings. It is only within the last few weeks, I was called to visit a widow lady, left with two lovely children with ample means; every comfort that money could produce. She fell into this deplorable practice, and when last called to her, I found her stiff and cold. She had passed away in a state of beastly intoxication. In several cases, after every expedient that could be thought of, a lunatic asylum becomes our only resource.

But to turn from this revolting, heart-rending subject, I greatly fear your excellent suggestions for the establishment of peace are not likely to be followed out. What a strange compound is man? One hundred thousand human beings, have been sent before their Creator, with feelings of rancour and hatred in their hearts, and all for what? Some paltry slip of territory, the right to which could readily be adjusted by arbitration. Verily the heart of man, as the Scriptures informs us is a nest of unclean birds. What we all want is Charity. "My commandment is that you love one another as I have loved you. He that loveth his neighbour hath fulfilled the law" (Rom. xiii.). "By charity alone," says St. Augustin, "the children of God are distinguished from the children of Satan." But I must bring to a close this long, prosy rambling detail, and by way of a little enlivenment, I shall conclude by giving you an anecdote, recorded by the Marquis of Lansdown. His lordship went up to pat a horse, which he had just before corrected with a whip, when he was checked by the warning voice of the groom. "Don't go near him, my Lord? They bear malice for all the world like Christians!"

Yours truly,
"Medicus."

My Dear Sir,—I felt greatly obliged by your long and most interesting letter. It must be a very pleasant reflection to you to know, that the opinions you held and lectured on years ago respecting the dangers resulting from the use of alcoholic liquors, are at length becoming the general sentiment of the Medical Profession. What we have now to contend with is, the scientific feeling that alcoholic liquors when used in very small quantity, are beneficial,—but the craving desire for them which pervades all classes (the rich quite as madly as the poor), and which, like the use of tobacco and other stimulants injurious to man,—overbears all sense and reason, and causes the slaves of these habits to attribute their ailments to any cause rather than to the real destroyer, which has gotten them so completely in his power. In order to help on the progress of truth in regard to this matter, I would like to make your excellent remarks public, and as your *name* would add great weight to them, I ask your permission to publish it also.

Very truly yours,
James Haughton.

35 Eccles street, Dublin, September 3rd, 1870.

Tuesday, September 6th, 1870.

My Dear Sir,—A few hurried lines written in an unreserved gossiping kind of way, and in the midst of professional engagements of one kind or another, could hardly be expected to assume a costume suited to the keen discerning eye of a fastidious public. Moreover, at my advanced period of life with one foot in the stirup, as Sancho Panzas says, or as we say in Ireland, with the daisy quilt ready to receive you at a moment's warning, I am, I confess, although my sentiments are pretty well known to the profession and in a small way to the community at large, on the all important subject of temperance, averse to place myself in a prominent position before the public. Repose, tranquillity, retirement, are more suited to my tastes; I am, therefore, averse that my name should be attached to any document on the subject. If, however, the scanty materials in your hands are at all calculated to promote an object so meritorious, and which you have so much at heart, I am willing you should give them publicity under an assumed name, or *nom de plume* as we say.

Well now, as we are on the subject of temperance, there is one question I should like to ask. Suppose the object fully accomplished—How is the revenue of the country to be met? No doubt you would have your working classes better clad; their abodes better furnished; their children instead of infesting our streets in a state of semi-nudity, while their mothers, as I have repeatedly known, are tippling behind our attractive spirit casks in the neighbourhood. Your gin palaces would be abolished, and instead, you would have vaccine institutions or in plain English, you would have the honest dairyman, instead of being hustled up in an obscure corner, assume his proper position, dispersing the wholesomest nutriment ever offered by the Almighty, for the support of man. Look all through Creation. What do we find, but milk in some forms, furnished by the bountiful hand of the Creator, for the support of the young of all animals in their helpless, feeble condition. All this is very true, but still they are not *excisable* articles, and I confess I do not see clearly, how the deficiences are to be supplied in the event of the suppression of the manufacture of all alcoholic drinks? With great respect,

Believe me, my dear Sir, yours very truly,
"Medicus."

P.S.—"Medicus" has started a difficulty on the question of Revenue, in case the advocates of "Permissive Bill" legislation shall be successful in carrying their measure, which demands a few words in reply from me.

When that measure shall be enacted, it will only come into effect gradually, throughout the kingdom; leaving ample time to the Chancellor of the Exchequer to regulate his Budget from other sources. A much smaller revenue will then answer all his purposes, as the expenses needed for governing the Nation will obviously be much smaller in amount.

Our local taxation will be greatly lessened; as we shall then have few criminals to punish; little poverty to relieve; and not one half the sickness and insanity which must now be provided for, to guard against. These happy results are already experienced at Saltaire, and in numerous other places in England. And in Ireland, in the County Tyrone, and in the town of Bessbrook, both on a large scale (comprising about 14,000 inhabitants), and throughout the United Kingdom, upon many private estates, the details of which it would occupy too much of your space to enter upon.

The sum now destroyed annually in great Great Britain and Ireland, by the use of poisonous alcoholic compounds, amounts to nearly two hundred and thirty millions of pounds sterling. When the operation of the "Permissive Bill" shall direct this enormous sum, out of ruinous, into improving, channels of expenditure, it is obvious that the revenue of the kingdom must be improved by the change; and also, that no good national work need be set aside, or postponed, for want of ample funds for its accomplishment.

These are a few of my reasons for supposing that the fears of "Medicus" on the subject of Revenue, are groundless; and also for the opinion which I often give public expression to, that to the cruel and most indefensible liquor traffic, may be fairly traced nearly all the crime and poverty which afflict the land.

James Haughton.

Obituary.

WM. CHOWNE, M.D., F.R.C.P.

The subject of this brief notice became a member of the College of Surgeons in 1813, and soon after commenced practice in the populous district of Holland in Lincolnshire. In 1827, he graduated in the University of Edinburgh, left his country practice, and became a member of the College of Physicians of London, at which College he obtained his diploma of Licentiate in 1833. Soon after he commenced practice in London, and was elected to the office of Physician Accoucheur to the St. George's and St. James's Dispensary. This office, however (in which he was succeeded by Sir James Eyre) he resigned, in order to become a candidate for that of Assistant Physician to the Charing Cross Hospital. The election terminated in Dr. Chowne's favour, and from

that time up to 1869 he has taken a most active share of the duties, both of the hospital and the medical school attached to it. He for many years occupied the obstetric chair, giving the whole of the lectures in this department as well as a portion of those upon Medical Jurisprudence.

Dr. Chowne was President of the Westminster Medical Society in its palmy days, and was one of the few who stood by it in its difficulties, when its home was the Hunterian Museum in Windmill Street. He also lent it valuable service upon its recovering its prosperity at the epoch when the good understanding always existing between the Westminster Medical Society and the Medical Society of London, led to a union of the two; which the high repute and the orthodox character of each rendered the more easy. The two societies by this arrangement became joint proprietors of a valuable library of many thousands of scarce and important volumes; of a freehold property, the bequest of the late Dr. Lettsom; and of two medals annually, (a gold and a silver one) bequeathed by the late Dr. Fothergill also to the Medical Society of London. The negotiation of this union was conducted by a deputation from each society, and Dr. Chowne, who was chosen as a member of the deputation on the part of the Medical Society of London, greatly assisted the happy issue.

Dr. Chowne was much liked as a teacher. His profession appears to have been a labour of love to him; and from the cares and duties of a most active life he managed to snatch sufficient leisure to devote himself to a long-cherished idea for the amelioration and improvement of our sanitary regulations, and, ere his demise, the adoption by sanitary reformers of his ideas, must have been highly grateful to him.

THE LATE MR. JOHN GUY OF SWINDON.

Another pupil of Abernethy has passed away in Mr. Guy, of Swindon, who, after a career of half a century, in which he had earned the love of the community in which he moved, reposes from his labours. His son who had succeeded him in practice, died last December.

MR. BRETT.

The death is also announced of Mr. E. S. Brett, of Bridlington, in Yorkshire, where he had practised nearly forty years.

DR. FEARN, F.R.C.S.

Samuel W. Fearn, of Derby, has also passed from among us. He was a very skilful operator, and one of the first to amputate through the knee-joint. He had successfully also removed the upper and lower jaw, and on three occasions had removed the os calcis.

NOTICES TO CORRESPONDENTS.

DANGEROUS NAMES.

Dr. De Chaumont and Count Wallowicz, both in our Army, and both British citizens, were to go to the war, but others have been substituted—it is said, on account of their names. The *Edinburgh Courant* thus writes about it:—

"'What's in a name!' Treachery—breach of neutrality—national complications—possible precipitation of Britain into war—and all sorts of impossible things. So, at least, thinks Earl Granville, who really seems to be in a chronic state of consternation lest he should give offence to one or other of the combatants on the Continent. The noble Lord has just given the last finishing touch to the ridiculous and nerveless character of his foreign policy by countermanding the journey of a respectable citizen of Edinburgh (who, as staff surgeon, had been appointed to proceed on a medical mission to the seat of war), because that gentleman happened to bear a French patronymic! Dr. De Chaumont cannot be allowed to perform a service, for which he is peculiarly qualified, because Earl Granville, forsooth, is afraid Count Bismarck may be offended by the sound of his name! To complete the farce, it only requires that his Lordship should, with his usual amiability, be induced to reconsider his decision, and to provide Dr. De Chaumont with a note of introduction to Bismarck, somewhat after the following apologetic fashion:—'Dr. De Chaumont, whom we send to gather information which may be useful to our wounded in the future, is the very best man we have for the purpose; but, as he, though a British subject, is of French extraction, and was baptized by a French name, I beseech you not to eat him—for he really could not help it.' Clearly Mr. Disraeli was wrong when he said that national politics were now conducted on parish principles. Even Bumbledom will wield its wand of authority with more firmness than Lord Granville can muster to stiffen the seals of office between his trembling fingers."

ETIQUETTE.

To the Editor of "The Medical Press and Circular."

Sir,—Allow me to agree with the remarks of your correspondent, "Cantharides," on the subject of the "Roasted-Apple Association," and to ask—Medical Press and Circular excepted—if the editors of certain professional journals, who preach etiquette and presume to teach us how to perform our duties, practice etiquette themselves, that is, the professional etiquette of the journalist? Does it consist in shutting the portals of their organ to those whose only sin is the fact of their contributing to other papers? Is it professional etiquette to be told, "If you write for us alone, we shall gladly accept your MSS., but you must confine yourself to us!" This does not altogether refer to the "Roasted-Apple Association." Has the Wandering Jew heard of the *Persian Iris*, which appears only to some to possess a sweet perfume, whilst to the majority it is scentless. God knows we are sick of this green *agrafias* and orange-coloured *auriculas*. We want sincerity of principle as much as we detest cliqueism and jealousy.

I am, &c.,

Another Member of the Roasted-Apple Association.

THE RELATIVE VALUE OF DEGREES.

To the Editor of "The Medical Press and Circular."

Sir,—You would greatly oblige by submitting the following to the columns of your valuable paper. Being a medical student myself, and desirous of knowing the best school or college from which to take a degree, I should wish to know whether the Dublin Schools of Anatomy, or the degrees granted by them, are looked down upon in England or the Colonies. Hoping that some of your readers may afford me information,

I am, &c., &c., De Burgh Griffith.

*** The Licenses of Irish Corporations and Universities occupy the highest position, and confer on their holders prestige quite equivalent to those of any English body. For English Poor-law appointments, the London College of Surgeons, and Apothecaries' Hall, are *de rigueur*, and would give to their Licentiates a higher consideration than Irish diplomas.—Ed. M. P. & C.

The pressure on our space caused by the proceedings of the two Scientific Congresses, compels us to hold over several original communications, letters, and other material.

Correspondents not answered are requested to look at "Notices" the following week.

Dr. Ross.—Report received.

J. B. Browne.—Proofs shall be sent.

F. R. S.—The Sewage Question came up both at Liverpool and Newcastle.

R. S.—Notes of the case would be acceptable. Brevity is no objection—quite the contrary.

LL.D.—You are quite justified in naming your qualifications and appointment in the title-page of your book.

A Poor-Law Doctor.—The fee seems to us very moderate.

A Celibate.—We cannot insert your letter. It is not medical, not even physiological, but purely theological, and so quite outside the range of a medical journal. The controversy is closed, as you could have noticed in our last impression. It was necessary to admit replies to a phrase which might offend some, and which, had we not accidentally overlooked, we should not have inserted.

Mr. Haviland.—The abstract has been received.

F.R.S.—Our contemporary is quite mistaken.

Hygienicus.—The matter is being discussed by the Social Science Congress, and some report will be furnished in our columns.

Mr. Hind.—Your request will be complied with.

VACANCIES.

West Riding Lunatic Asylum, Wakefield.—Assistant Medical Officer. (See advertisement.)

Sevenoaks Union.—Medical Officer. Salary £35, with extras.

Northumberland County Lunatic Asylum.—Assistant Medical Officer. Salary £85.

Central London District Schools.—Resident Assistant Medical Officer at Hanwell. Salary £100, with board and residence.

Liverpool Dispensaries.—Resident House Surgeon at £140, and two Assistant House Surgeons at £103 per annum, each with residence, &c.

North Riding.—Gaol Surgeon. Salary £100, inclusive of medicines.

Kidderminster Infirmary.—House Surgeon. Salary £100, with residence.

APPOINTMENTS.

Burge, F. J., sen., M.R.C.S., Medical Officer for the Hammersmith District of the Metropolitan Mutual Aid Society.

Douglas, A. E., M.D., Medical Officer for the Warrenpoint Dispensary District of the Newry Union, Co. Down.

Duke, S., M.D., Medical Officer for the Camberwell New-road District of the Metropolitan Mutual Medical Aid Society.

Eagar, R., M.D., Resident Superintendent to St. Luke's Hospital.

Fussell, E. F., M.B., M.R.C.P., Assistant-Physician Sussex County Hospital.

Greene, R., L.R.C.P., Assistant Medical Officer to the Sussex Lunatic Asylum, Haywards heath.

Hilliard, H. C., M.D., Medical Tutor and Demonstrator of Anatomy to Queen's College, Birmingham.

Huston, R. T., L.K.Q.C.P.I., Medical Officer for District No. 4 of the Holsworthy Union, Devon.

Jervis, C., M.R.C.S., House-Surgeon at St. Mary's Hospital.

Kempe, C. P., M.R.C.S., Medical Officer for the Camden-town District of the Metropolitan Mutual Medical Aid Society.

Pottle, J. R., M.R.C.S., Medical Officer for the City-road District of the Metropolitan Mutual Medical Aid Society.

Rosser, W., M.B., M.R.C.S., Resident Medical Officer to, and Lecturer on Chemistry at, Trinity College, Glenalmond, Perth.

Timothy, P. V., M.D., Medical Officer for the Finsbury District of the Metropolitan Mutual Medical Aid Society.

Turner, G. E. W., L.R.C.P.Ed., Assistant Medical Officer at the Cotonhill Lunatic Asylum, Stafford.

ANALYTICAL REPORT
ON
BEBE'S DUBLIN XXX PORTER.
By MR. TICHBORNE, F.C.S., &c.,
Apothecaries' Hall, Dublin.

FROM the evidence given before the Parliamentary Committee, and from the published reports extant, it would appear that most of the great porter brewers do not adulterate. The nearest approach to anything of this kind would seem to be in the use of salt, and that only to a moderate degree. It is, however, equally well known that, as a rule, the porter is not bottled by the brewers, but by men who make bottling a special business; or, what is more frequently the case, it is bought in the wood by the publicans, or retailers, and bottled by them. It is self-evident that the name of a good brewer upon the label is not always a guarantee for the quality of the porter.

The object of the present report is to examine the quality of porter sent out by one of the best known bottlers in Dublin. The bottles were labelled, "*Guinness's Dublin Stout, XXX, Brewed for Exportation. Bottled by John Bebe.*"

We give the result in a tabular form :—

(Specific gravity, 1·0195.)	Grains per gallon
Alcohol (proof spirit)	7,630
Solid matter	4,816
Saccharine matter	2,300
Ash	126
Albuminous substances (nitrogen, 132 per cent.)	574
Acidity (acetic acid)	245

It is evident from the above analysis that this bottled porter represents fairly Guinness's XXX stout, a genuine and pure porter containing more than the average quantity of alcohol.
